> He left me pretty much alone, but we had nice discussions about physics and became better acquainted. He gave me one personal lecture that I remember well: "You know, Hans, the thing is this, either you do good physics or you do really creative applications. I would hate to see you, as my student, making nothing out of technology but doodle signs, so to speak, and nothing really creative." I told him about my ideas on the turbine for aircraft and he said, "When you have something which really revolutionizes technology by employing physics, this is fine, but don't do mediocre stuff." He encouraged me very much to go into the applications area because "You have a flair and a talent for that."

Ohain's independence in proposing and pursuing his doctoral dissertation research topic was central to Pohl's written evaluation of that dissertation when it was completed [Conner 2001, p. 23]:

> The light relay constructed by Mr. von Ohain has meaning, not only for the technical purpose specified in the work, but is also adaptable for application in many physical tasks. Mr. von Ohain conceived the idea for this design entirely on his own and carried out the physical investigation of the relay's characteristics with a refreshing self-reliance. With the completion of the work, not only has he pulled off a great experimental undertaking, but also demonstrated the ease with which he could apply his knowledge of theoretical physics to practical problems. I can without reservation recommend a grade of "Very Good" for Mr. von Ohain's work.

Similarly, Wernher von Braun was able to pursue his own ideas for rockets as a doctoral dissertation, with the support of Erich Schumann as his advisor [Neufeld 2007, p. 68]:

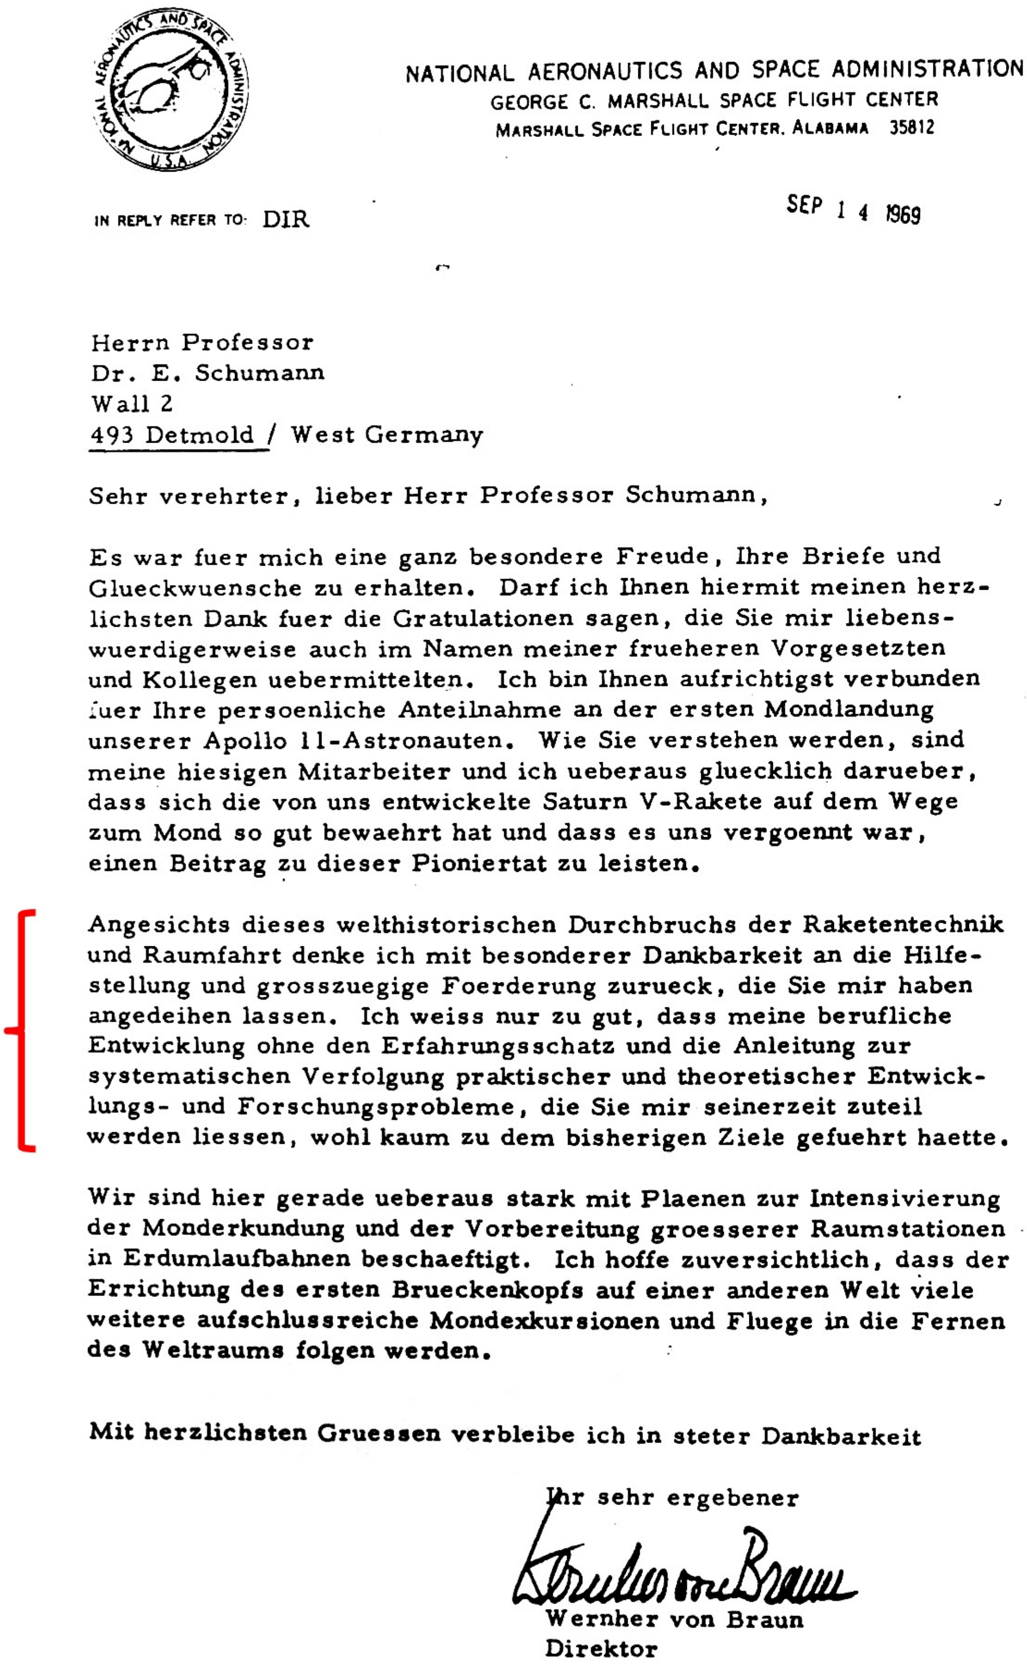
> As spring finally came to northern Germany, von Braun completed his University of Berlin physics dissertation, “Design, Theoretical and Experimental Contributions to the Problem of the Liquid-Fuel Rocket,” in mid-April. A major section on the theory of combustion in a rocket engine can fairly be described as physics, but most of the typescript was actually an engineering treatise on his rocket motors, the A-1 vehicle, and the test instrumentation. Ordnance considered the work so sensitive that the dissertation was given a cover name, “Regarding Combustion Experiments,” a boring and opaque pseudotitle that would appear in his graduation paperwork and on his doctoral diploma. Schumann and Wehnelt, his two examiners in physics, were so impressed with the work that they gave it the Latin distinction “*eximium*”—extraordinary, the highest possible grade.

As shown in Fig. 10.7, in a 14 September 1969 letter (after the first manned moon landing), Wernher von Braun wrote to Erich Schumann [Bundesarchiv Militärarchiv Freiburg N822/6]:

> Angesichts dieses welthistorischen Durchbruchs der Raketentechnik und Raumfahrt denke ich mit besonderer Dankbarkeit an die Hilfestellung und grosszuegige Foerderung zurueck, die Sie mir haben angedeihen lassen. Ich weiss nur zu gut, dass meine berufliche Entwicklung ohne den Erfahrungsschatz und die Anleitung zur systematischen Verfolgung praktischer und theoretischer Entwicklungs- und Forschungsprobleme, die Sie mir seinerzeit zuteil werden liessen, wohl kaum zu dem bisherigen Ziele gefuehrt haette.

> In view of this world-historical breakthrough in rocket technology and space travel, I think back with special gratitude to the support and generous encouragement you have given me. I know only too well that my professional development would hardly have led to my present goals without the wealth of experience and guidance in the systematic pursuit of experimental and theoretical development and research problems that you gave me at the time.

Just as von Ohain and von Braun were allowed to pursue their own revolutionary ideas as students, once they received their Ph.D.s, people like Ernst Heinkel (p. 2009) gave them the freedom and resources to continue to pursue their own ideas. The other creators were similarly successful in being able to continue to pursue their own ideas.



NATIONAL AERONAUTICS AND SPACE ADMINISTRATION

MARSHALL SPACE FLIGHT CENTER, ALABAMA 35812

IN REPLY REFER TO: DIR

SEP 14 1969

Herrn Professor
Dr. E. Schumann
Wall 2
493 Detmold / West Germany

Sehr verehrter, lieber Herr Professor Schumann,

Es war fuer mich eine ganz besondere Freude, Ihre Briefe und Glueckwuensche zu erhalten. Darf ich Ihnen hiermit meinen herzlichsten Dank fuer die Gratulationen sagen, die Sie mir liebenswuerdigerweise auch im Namen meiner frueheren Vorgesetzten und Kollegen uebermittelten. Ich bin Ihnen aufrichtigst verbunden fuer Ihre persoenliche Anteilnahme an der ersten Mondlandung unserer Apollo 11-Astronauten. Wie Sie verstehen werden, sind meine hiesigen Mitarbeiter und ich ueberaus gluecklich darueber, dass sich die von uns entwickelte Saturn V-Rakete auf dem Wege zum Mond so gut bewaehrt hat und dass es uns vergoennt war, einen Beitrag zu dieser Pioniertat zu leisten.

Angesichts dieses welthistorischen Durchbruchs der Raketentechnik und Raumfahrt denke ich mit besonderer Dankbarkeit an die Hilfestellung und grosszuegige Foerderung zurueck, die Sie mir haben angedeihen lassen. Ich weiss nur zu gut, dass meine berufliche Entwicklung ohne den Erfahrungsschatz und die Anleitung zur systematischen Verfolgung praktischer und theoretischer Entwicklungs- und Forschungsprobleme, die Sie mir seinerzeit zuteil werden liessen, wohl kaum zu dem bisherigen Ziele gefuehrt haette.

Wir sind hier gerade ueberaus stark mit Plaenen zur Intensivierung der Monderkundung und der Vorbereitung groesserer Raumstationen in Erdumlaufbahnen beschaeftigt. Ich hoffe zuversichtlich, dass der Errichtung des ersten Brueckenkopfs auf einer anderen Welt viele weitere aufschlussreiche Mondexkursionen und Fluege in die Fernen des Weltraums folgen werden.

Mit herzlichsten Gruessen verbleibe ich in steter Dankbarkeit

Ihr sehr ergebener

Wernher von Braun

Wernher von Braun
Direktor

Figure 10.7: 14 September 1969 letter from Wernher von Braun (after the first manned moon landing) thanking Erich Schumann, who had been his Ph.D. advisor in the 1930s [Bundesarchiv Militärarchiv Freiburg N822/6].

It is interesting to note that this frequent (but not universal) style of mentorship in academia was similar to the frequent (though not universal) style of management in science and engineering companies, suggesting that this tendency was a general (but not universal) element of German-speaking culture. For example, immediately after World War II, Allied investigators visited the Leitz company and wrote a glowing report about what they found [BIOS 1436 pp. 10–11]:

> 60. The main items of production at the time of inspection, besides the Leica camera, were binoculars, projection apparatus and microscopes. The microscopes included the H. Powder Binocular, Students, Panphot and Ortholux. [...]
>
> 61. The Leitz factory is a well-run, happy organisation, this being due in no small measure to the family nature of the business and to its importance in the neighborhood. Discipline is strict without being severe and one gets the impression of great interest by employees of every grade in the work being performed.
>
> 62. This pride in workmanship and the just pride all have in their world-wide reputation for quality work is the permeating spirit of the place and helps greatly to offset apathy caused by the present dismal state of the country.
>
> 63. The products coming from the Leitz works are equal to any turned out before the war although in some cases the finish is inferior due to poor materials, especially paints and enamels.
>
> 64. The team came away with the impression that the Leica camera is still worthy of its pre-eminent position and that the skill of the craftsmen is very much in evidence in the Leitz factory.

Thus many German-speaking companies, like many German-speaking academic labs, treated junior members as craftsmen who should be aided and rewarded in developing their own skills and given their proper place. In the modern U.S. system, unfortunately too many senior people in both academia and industry seem to consider students or employees to be interchangeable, disposable units whose primary purpose is to enrich the professors or executives at the top (see Section 1.1 and references therein).

10.2.4 Average Age for Final Degree

The ages at which the German-speaking creators received their highest degrees (not counting those whose education was delayed by factors such as war, work, or illness) tended to be remarkably low by modern standards, or even by the standards of the early U.S. research system. A major reason is that in the older German-speaking world, students could (and very often did) graduate from the Gymnasium (the German-speaking equivalent of a U.S. high school) at age 18 or so, then directly enter a doctoral program at a university and receive their final degree four or so years later.[2] In contrast, students in most of the modern world (and even in the early U.S. research system) typically spend many years earning a bachelor's degree (and often a master's degree) between the time they graduate from high school and when they finally enter a doctoral program. Modern doctoral programs can also be much longer than those in the earlier German-speaking world, although that does not necessarily mean that they are better.

As a representative data set to illustrate this pattern of ages for final degrees, one can consider scientists who were educated primarily or entirely in the German-speaking world and:

1. Won a Nobel Prize in Physiology or Medicine prior to 1991 (Table 10.3, choosing this cutoff date to exclude most of those who were educated after 1945).

2. Won a Nobel Prize in Chemistry prior to 1991 (Table 10.4).

3. Won a Nobel Prize in Physics prior to 1991 (Table 10.5).

4. Created certain major innovations but did not win a Nobel Prize (Table 10.6, to pick some representative major creators who worked in fields such as engineering, mathematics, earth science, and other areas not considered for Nobel Prizes).

In order to keep the data set focused on the German-speaking educational system, scientists who had some of their training in that system but a significant part of their training outside that system (e.g., Americans such as Irving Langmuir who completed their education in Germany, or Germans such as Ernst Chain who completed their education outside the German-speaking world) are omitted from these tables.

Unless otherwise noted, all of the individuals in these four tables graduated with a Ph.D. Where noted, some received an M.D. (especially among the winners of a Nobel Prize in Physiology or Medicine). As indicated in the tables, a handful of these individuals (such as Albert Einstein) graduated with a final degree that was not a doctorate. As also noted, a few individuals were delayed in receiving their final degree, due to military service, war disruptions, serious illness, or work obligations.

---

[2] See for example: Arnold 1882; Ash 1997; Beier 1902; Ben-David 1992; Brown 1911; Herrlitz 2009; Paulsen 1906, 1908; Röhrs 1995; Russell 1899; Schrader 1893; Schwinges 2007.

Students could graduate at any time of year, depending on when their doctoral thesis was completed and approved. In most cases only the year of graduation and not the exact date was readily available. In such cases, the graduation was assumed to have occurred on average in the middle of the year, and the students' ages at graduation calculated accordingly. Any errors caused by this assumption should mostly cancel each other out when averages are taken over entire groups of people.

Nobel Prize	Name	Born	Graduated	Age
1901	Emil von Behring	15 March 1854	1878	24 (M.D.)
1905	Robert Koch	11 December 1843	January 1866	22 (M.D.)
1908	Paul Ehrlich	14 March 1854	1882	28 (M.D., work)
1909	Theodor Kocher	25 August 1841	March 1865	23 (M.D.)
1910	Albrecht Kossel	16 September 1853	1877	23 (M.D.)
1914	Róbert Bárány	22 April 1876	1900	24 (M.D.)
1922	Otto Meyerhof	12 April 1884	1909	25 (M.D.)
1924	Willem Einthoven	21 May 1860	1885	25 (M.D.)
1927	Julius Wagner-Jauregg	7 March 1857	1880	23 (M.D.)
1929	Christiaan Eijkman	11 August 1858	13 July 1883	24 (M.D.)

Table 10.6: Ages at final degree for selected scientists who were educated primarily or entirely in the German-speaking world and created major innovations but did not win a Nobel Prize.

Table 10.7 summarizes the average ages at graduation for the scientists from Tables 10.3–10.6, excluding those whose education was delayed by war, work, or illness. These German-speaking creators tended to receive their highest degree at:

- Between ages 22 and 23 for a Ph.D. This pattern holds across all fields, as illustrated by the examples in Tables 10.3–10.7.
- Between ages 23 and 24 for an M.D. In the German-speaking world, obtaining an M.D. generally required about one year longer than obtaining a Ph.D.

Using these same methods, Section 11.2.4 analyzes the ages at graduation for scientists who were educated primarily or entirely in the United States and won a Nobel Prize in Physiology or Medicine, Chemistry, or Physics prior to 1991. For ease of comparison, the results of that analysis (again excluding those whose educations were delayed) are also summarized here in Table 10.7. As may be seen, on average those U.S.-educated scientists took approximately two years longer to complete their education than their contemporary counterparts from the German-speaking world. A two-year head start on an independent research career can be quite significant, especially when those are two years when the scientists are at the peak of their creative powers and energies, and presumably less hindered by obligations to family and bureaucracy than they would be later in their careers.

As a further comparison, the current situation in the U.S. educational system is even worse. For those receiving a doctorate in 2017, the median age at graduation was 31.6 [https://ncses.nsf.gov/pubs/nsf19301/data]. That is nearly a decade older than students who received a Ph.D. from the earlier German-speaking world.

Category of people	**Age at graduation from German-speaking world**	**Age at graduation from U.S. system**
Ph.D., Physics Nobel 1901–1990	23.2 years	25.1 years
Ph.D., Chemistry Nobel 1901–1990	22.4 years	24.7 years
Ph.D., Medicine Nobel 1901–1990	23.6 years	25.2 years
M.D., Medicine or Chemistry Nobel	23.8 years	25.0 years
Final degree, all science Nobelists	23.0 years	24.9 years
Ph.D., non-Nobel sample	22.4 years	—
Ph.D., Nobel + non-Nobel sample	22.7 years	25.0 years
M.D., Nobel + non-Nobel sample	23.8 years	25.0 years
Final degree, Nobel + non-Nobel sample	22.9 years	24.9 years

Table 10.7: Ages at final degree for selected scientists educated in German-speaking and U.S. systems.

A modern observer might object that students need to learn much more now, yet physics, chemistry, mathematics, engineering, and other fields had already been well developed by the early twentieth century, and German-speaking students took extensive coursework in them. For example, Hans Bethe's university transcripts show that he took the courses listed in Table 10.8 [Schweber 2012, pp. 402–403, 419–420]:

Differential and Integral Calculus I with Exercises
Higher Arithmetic
Exercises for Higher Arithmetic
Experimental Physics I
The Experimental Foundations of Atomistics
General Chemistry I (Inorganic Chemistry)
Accounting with Exercises
Mechanics
Exercises in Mechanics
Experimental Physics II
General Physical Chemistry
General Chemistry II (Inorganic Chemistry)
Seminar on Inorganic Chemistry
Inorganic Chemistry Laboratory
The Mechanical and Electrical Properties of Matter
The Foundations of Modern Physics
Organization of People and States
Differential Geometry
Special Topics in Theoretical Physics (Quantum Theory, Theory of Relativity)
Modern Spectroscopy
Physics Laboratory for Beginners
Electrochemistry
Chemical Thermodynamics
Seminar on Inorganic Chemistry
Chemical Laboratory in Inorganic Chemistry
Differential Equations in the Real Domain
Exercises in Differential Equations
Mechanics
Advanced Experimental Physics I: Mechanics, Acoustics, Heat
Exercises in Advanced Experimental Physics
Universal Physical Constants and the Methods of Their Determination
Exercises in Theoretical Physics
Physical Laboratory for Advanced Students
General Chemistry II: Atomics
Chemical Laboratory in Inorganic Chemistry
Continuum Mechanics (Carathéodory)
Physical Chemistry II
Chemical Forces and Constitution
Partial Differential Equations of Physics
Exercises—Partial Differential Equations of Physics
Theory of Magnetism
Theory of Band Spectra
Dispersion of Light and X-Rays
Physics Exercises for Advanced Students
Psychology
Introduction to Politics
Electrochemistry
Experiments in Electricity and Light
Theoretical Physics Seminar
Exercises—Mechanics
Selected Problems in Quantum Theory
Experimental Physics for Advanced Students
The Political Parties of the Reichstag
Colloid Chemistry
Experimental Methods, Properties, and the Theory of Crystal Lattices
Continuum Mechanics (Sommerfeld)
Exercises—Continuum Mechanics
Structure of Matter
Electrodynamics
Exercises—Electrodynamics
Quantum Mechanics
Physics of the Sun
Optics
Wave Mechanics
Theoretical Physics Seminar (Summer 1927)
Theoretical Physics Seminar (Winter 1927)
Theoretical Physics Seminar (Summer 1928)

Table 10.8: University courses taken by Hans Bethe.

Lest one worry that the quality of the above courses may not have matched their quantity, it should be noted that the classes on Bethe's transcript were personally taught by Walther Gerlach, Otto Hahn, Arnold Sommerfeld, Wilhelm Wien, and other scientific luminaries.

Bethe's university transcript is fairly typical for German-speaking science students of that time. The courses in a Gymnasium were so extensive, so advanced, and so rigorous that German-speaking students graduated at age 18 or so having already learned much of what modern students learn after high school for their bachelor's degree. Moreover, doctoral dissertations at German-speaking universities tended to focus much more on the novelty of the student's ideas and solutions than on how many years the student had toiled on that research. That allowed students in German-speaking doctoral programs to still spend several years taking a wide range of university courses. In contrast, many modern doctoral programs only allow students to take a few courses before they are expected to spend many years on the research assembly line for the rest of the program.

One might try to argue that modern Ph.D. students accomplish much more than students in the older German-speaking world by spending more of their university years doing research. However, the dissertation research of the German-speaking creators resulted in some of the seminal papers in their fields, whereas modern Ph.D. students may spend years toiling away primarily to pad their Ph.D. advisor's CV with extra papers that few people ever read.

The net effect is that the German-speaking creators were free to pursue independent research careers on average approximately two years sooner than their contemporary peers in the United States, and nearly a decade sooner than modern U.S. scientists. Relative to modern scientists, that means not just nearly a decade of additional work, but nearly a decade of additional work performed when the scientists were at their peak energy and creativity in life, and also generally less weighed down by family and professional obligations. That difference is demonstrated by the dramatic accomplishments of most of the German-speaking creators by the time they had reached 31 or 32 years old, the age at which average Ph.D. students are just finally graduating in the modern United States.

In fact, the real difference is even larger than that. Many (though certainly not all) of the German-speaking creators were able to conduct truly independent research as soon as they obtained their doctoral degrees, if not before. In contrast, scientists who receive a Ph.D. or M.D. in the modern U.S. system typically then have to spend many years following older supervisors' instructions in postdoctoral jobs (often multiple postdoctoral jobs in a row), residencies, or entry-level positions at corporate or government laboratories.

In 2020, the average age at which Ph.D. scientists received their first National Institutes of Health (NIH) research project grant was 43, and the average age at which M.D. scientists received their first NIH research grant was 46 [https://nexus.od.nih.gov/all/2021/11/18/long-term-trends-in-the-age-of-principal-investigators-supported-for-the-first-time-on-nih-r01-awards/]. **Thus many German-speaking creators achieved scientific and creative independence two whole decades in life earlier than scientists in the modern U.S. system.**

As discussed in more detail in Chapter 12, this data suggests that one way to improve the modern innovation system would be to eliminate redundancies between high school and undergraduate education, streamline the graduate school educational process, greatly lower the average ages at which scientists receive their final degrees and their first financial grants, and give young scientists much more independence during their most energetic and creative years.

10.2.5 Interdisciplinary Approach

Scientists who made major contributions to multiple disciplines, and fraternization among scientists from different disciplines, were much more common in the older German-speaking world than in the modern world. That interdisciplinary approach apparently facilitated production of and support for innovators and innovations.

Although broadly supportive innovation systems did not begin to assume a coherent form in the German-speaking world until the early nineteenth century, there were many examples of individual German-speaking creators who arose earlier, and who served as role models for the much larger numbers of later creators. Most of those early role models were strongly interdisciplinary, and they were revered by the German-speaking world for that trait (among others). As shown in Fig. 10.8, some examples included:

- Athanasius Kircher (German states, 1602–1680), who conducted groundbreaking research on geology and microbiology, analyzed Egyptian hieroglyphs, and built novel clocks, image projectors, and musical instruments [Findlen 2004; Joscelyn Godwin 2009].

- Gottfried Leibniz (Saxony, 1646–1716), who made major contributions to math, physics, engineering, computing machinery, geology, paleontology, biology, economics, philosophy, and other subjects [Antognazza 2009].

- Leonhard Euler (Swiss, 1707–1783), who did seminal work in math, physics, engineering, astronomy, optics, fluid mechanics, logic, and other areas [Calinger 2015; Richeson 2008].

- Johann Wolfgang von Goethe (German states, 1749–1832), who was revered for his novels, plays, poetry, memoirs, and studies in geology, paleontology, botany, color, and other fields [Douglas Miller 1988].

- Alexander von Humboldt (Prussian, 1769–1859), who made major contributions to botany, geography, meteorology, archaeology, and other subjects [Wulf 2015].

- Wilhelm von Humboldt (Prussian, 1767–1835), Alexander's older brother, who did important work in linguistics, philosophy, and political science, but had the greatest impact on the development of all levels of education in the German-speaking world [Borsche 1990].

These and other early multidisciplinary role models had a profound impact on the developing German-speaking innovation systems, making the German-speaking world especially enthusiastic about training, employing, and celebrating multidisciplinary scholars. In particular, Wilhelm von Humboldt's ideas were central to the German-speaking education and research systems. As already noted (see p. 1965), those ideas of Bildung included (1) promoting learning for its own sake, not just to enter a career, which encouraged education that was much broader than was actually needed by any specific job, and (2) promoting lifelong learning, long after leaving formal schools, which allowed a person to explore more and more fields over the course of a lifetime.

Figure 10.8: Some examples of very early, highly influential interdisciplinary scholars in the German-speaking world included Athanasius Kircher, Gottfried Leibniz, Leonhard Euler, Johann Wolfgang von Goethe, and the brothers Alexander and Wilhelm von Humboldt.

As a result of this longstanding and deeply ingrained multidisciplinary culture in the German-speaking world, there were a large number of creators in the nineteenth and twentieth centuries who made major contributions to multiple fields. Tables 10.9–10.10 list some representative examples. Even scientists who only worked in one field frequently rubbed shoulders with those in other fields, as students, as professors, at seminars and conferences, and in the coffeehouses outside of work. All of these interactions served to promote new insights and innovations within fields and cross-fertilization of ideas between fields.

That broad, interdisciplinary approach is in stark contrast to the microspecialization that is widespread in modern education and research.

Creator	**Fields of creations**
Otto Ambros	Magnetic recording, synthetic rubber, organophosphates
Manfred von Ardenne	Television, electron microscopes, radar, nuclear physics, plasma physics
Heinrich Barkhausen	Magnetic recording, radar
Emil(e) Berliner	Microphone, record player, helicopter
Friedrich Bessel	Astronomy, mathematics
Felix Bloch	Solid state physics, NMR/MRI, nuclear physics, radar
Konrad Bloch	Cholesterol metabolism, hormones, fatty acid metabolism
Karl Braun	Radio, television, radar, semiconductor devices
Adolf Butenandt	Hormones, gene mutations
Peter Debye	Photons, solid state physics, solution chemistry, polymers, X-ray diffraction
Max Delbrück	Quantum electrodynamics, radiation, DNA mutations, bacteriophage
Krafft Ehricke	Rockets, nuclear engineering, solar system
Walter Elsasser	Quantum physics, nuclear physics, geomagnetism, systems biology
Anton Flettner	Teleoperated robots for land, water, and air; rotor ships; helicopters
James Franck	Photoelectric effect, nuclear physics, photosynthesis
Otto Frisch	Quantum physics, nuclear physics, laser scanning
Gustav Fritsch	Neuroanatomy, zoology, astronomy, ethnography
Herbert Fröhlich	Solid state physics, biophysics
George Gamow	Nuclear physics, cosmology, genetic code
Carl Friedrich Gauss	Mathematics, astronomy, electromagnetism, telegraph
Thomas Gold	Astronomy, biophysics, aerospace engineering, geophysics
Peter Goldmark	Television, phonograph, magnetic recording
Hermann Grassmann	Math, physics, linguistics
Helmut Gröttrup	Avionics, rockets, chip card
Erich Habann	Radar, rockets, semiconductors
Hermann von Helmholtz	Vision, hearing, electromagnetism, thermodynamics
Ulrich Henschke	Prostheses, neural interfaces, cancer brachytherapy, flight simulators
Gerhard Herzberg	Molecular spectroscopy, molecular structures, free radicals
George de Hevesy	Chemistry, nuclear physics, biomolecule isotope labels
Fritz Houtermans	Nuclear physics, astrophysics, geophysics

Table 10.9: Some examples of German-speaking creators who made contributions in multiple fields.

Creator	**Fields of creations**
Gustav Franz Hüttig	Nuclear physics, radar, rockets
Theodore von Kármán	Solid state physics, aerodynamics, R&D strategy
Gustav Kirchhoff	Circuits, spectroscopy, elements, thermal radiation
Richard Kuhn	Vitamins, organophosphates, antibiotics
Hermann Lehmann	Hemoglobin, pharmacokinetics
Ernst Mach	Aerodynamics, optics, relativity, hearing/balance
Hans Mauch	Jets, prostheses, neural interfaces, space suits, aviation controls
Walther Nernst	Thermodynamics, chemistry, solid state physics, acoustics
John von Neumann	Mathematics, computers, physics, economics, etc.
Heinrich Olbers	Astronomy, mathematics, ophthalmology, vaccination
Rudolf Peierls	Solid state physics, Manhattan Project
Auguste Piccard	Atmospheric science, cosmic rays, oceanography
Michael Polanyi	Physical chemistry, materials science, medicine, economics, philosophy, epistemology, etc.
Eugen Sänger	Space shuttles, ramjets, antimatter propulsion
Rudolf Schoenheimer	Biomolecule isotope labels, cholesterol/atherosclerosis
Erwin Schrödinger	Quantum physics, color vision, theoretical biology
Erich Schumann	Acoustics, shaped explosive charges, nuclear physics, rockets, biological weapons, chemical weapons
Werner von Siemens	Sea mines, telegraph, electric elevator, dynamos, speaker, trolley
Leo Szilard	Nuclear physics, statistical physics, molecular biology, etc.
Edward Teller	Nuclear physics, physical chemistry, climate change, etc.
Stanislaw Ulam	Nuclear engineering, computers, mathematics, bioinformatics
Rudolf Virchow	Cell biology, pathology, sanitation, archaeology
Herbert Wagner	Wings, jet engines, smart bombs, missiles, nuclear engineering
Hellmuth Walter	Rockets, aircraft, submarines
Emil Wiechert	Electron, electromagnetic fields, seismography, geophysics
Eugene Wigner	Physical chemistry, nuclear engineering, particle physics
Richard Willstätter	Chlorophyll, chromatography, gas mask filters, enzymes
Karl Zimmer	Nuclear physics, DNA mutation
Fritz Zwicky	Jet propulsion, astrophysics, ionic crystals and electrolytes

10.2.6 Scientific Leadership and Decision-Making Style

During the nineteenth and early twentieth centuries, German-speaking areas in Europe often tended toward rather autocratic styles of government, with examples including numerous regional monarchies before 1871 and some afterward, Otto von Bismarck, Kaiser Wilhelm II, and the Third Reich [Berghahn 2005; Fullbrook 2004; Kitchen 1996; Mann 1968; Thomson 1962]. Perhaps because of this culture, the German-speaking research world during this time was also populated by a number of autocratic leaders. Of course, an autocratic scientific leader can do great harm if that individual is personally malicious and/or scientifically incompetent, as demonstrated by the profoundly negative impact of Joseph Stalin's hand-picked biology leader Trofim Lysenko (1898–1976) on real biologists and real biology research in the Soviet Union for many decades. However, if autocratic scientific leaders are very well-intentioned and well-informed, they can potentially bypass a number of bureaucratic obstacles, champion promising ideas and talented scientists that might otherwise be overlooked by the crowd, and push rapid and sustained progress in key areas of research. The German-speaking research world appears to have greatly benefited from a number of such "enlightened despots" or technocrats during the nineteenth and early twentieth centuries.

These enlightened despots had different individual styles, various opportunities, and differing levels of success. They were all imperfect in their scientific judgment and/or personal character. Indeed, some of them had profound moral flaws that certainly should not be countenanced, let alone emulated. Nonetheless, like their counterparts in the 1940s–1960s U.S. research system (Section 11.2.6), each of these German-speaking despots had three characteristics that could also be useful in the modern research system:

- The strong and direct support of very high authorities (in many cases to the very top of the government).
- A keen eye for revolutionary innovators and innovations.
- The ability to directly offer steady employment and funding for any innovators and innovations they deemed worthy, essentially unencumbered by any bureaucratic processes for application, review, approval, renewal, etc.

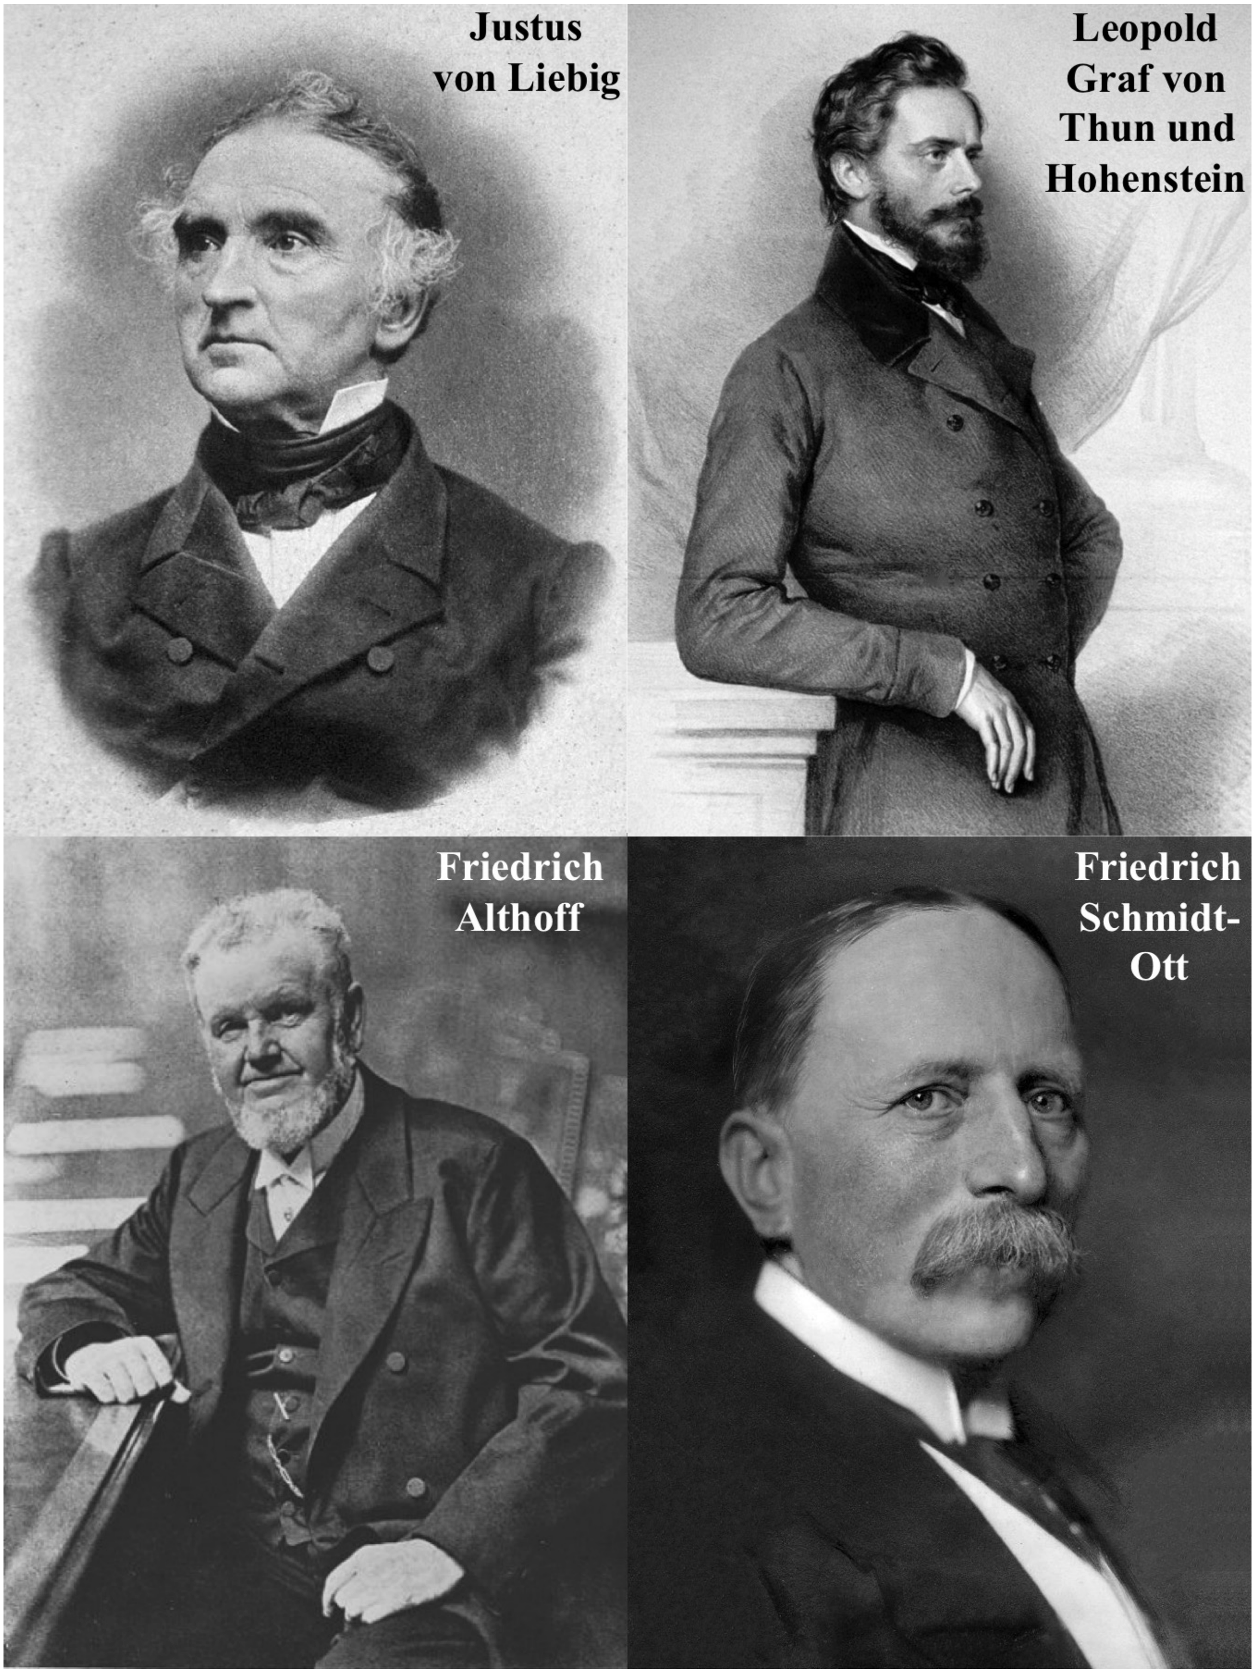
There were many examples of such enlightened despots in the German-speaking world; just a few are given in this section.

Justus von Liebig (German, 1803–1873), shown in Fig. 10.9, is considered the founder of organic chemistry and made major discoveries in biochemistry and botany. However, he made an even greater impact by designing the first formal university teaching curriculum and research program for chemistry, successfully lobbying for government funding for it, and recruiting and training over 700 students. Thus he was the father of all of the chemistry research and education system for which Germany became so famous, and the earliest of the enlightened scientific despots presented here. In the next century, the Nobel-Prize-winning chemist Fritz Haber wrote of von Liebig [Farber 1961, p. 537]:

> He felt in himself the call for an accomplishment for which no man's strength and life span could be sufficient. He meant to build up chemistry, of which there was nothing in Germany, and outside of Germany only a modest knowledge in the realm of inanimate nature, so richly and splendidly that there would be order, light, coherence, and system. Through his example and his teaching he meant to show the direction and pave the way for young people, the path which led to an understanding of the events in animate nature, and a new flourishing of industry. What he wanted has become in our day the common will of a great branch of science that he created. What we have gained was accomplished because the succeeding generations stood on his shoulders.

Leopold Graf von Thun und Hohenstein (Austrian, 1811–1888), also shown in Fig. 10.9, was the Austrian minister of education 1849–1860. In that capacity, he had a great impact by reforming Austrian universities and other schools and by hiring very innovative scientists and engineers. *Encyclopedia Britannica* summarized his approach [EB 1911, https://en.wikisource.org/wiki/1911_Encyclopædia_Britannica/Thun-Hohenstein]:

> At first he threw himself with great energy into the task of building up an adequate system of schools. He summoned experienced teachers, Protestant as well as Catholic, from Germany, established middle and higher schools in all parts of the empire, superseded the antiquated textbooks and methods of instruction, and encouraged the formation of learned societies and the growth of a professional spirit and independence among the teachers. It is noticeable that at this time he insisted on the use of German in all schools of higher education. [...] His high social position, his influence at court, his character, as well as his undoubted abilities and learning, not often in Austria found in a man of his rank, gave him great influence.



Justus von Liebig
Leopold Graf von Thun und Hohenstein
Friedrich Althoff
Friedrich Schmidt-Ott

Figure 10.9: Examples of scientific "enlightened despots" who had a very large impact on the German-speaking world: Justus von Liebig, Leopold Graf von Thun und Hohenstein, Friedrich Althoff, and Friedrich Schmidt-Ott.

Friedrich Althoff (German, 1839–1908), shown in Fig. 10.9, was perhaps the most important enlightened scientific despot in the history of the German-speaking world [Baumgart 1980; vom Brocke 1991b; Sachse 1928; Senn 1993]. Althoff's major position was the Prussian minister of culture for a quarter of a century, 1882–1907, in which capacity he held state government funding power over educational and research institutions within the Prussian state of the larger unified Germany. Yet because Prussia was the founding and most powerful state of unified Germany, and because Althoff had so many powerful connections and was so talented with Machievellian political methods behind the scenes, his power was immense and reached throughout the German-speaking world, even assisting Arnold Sommerfeld in Bavaria.

Althoff gave direct financial and political support to a large number of scientists who ultimately made major discoveries, many of whom in turn also acted as enlightened despots to offer financial and political support to later talented young scientists. Some scientists and engineers who directly benefited from Althoff's support included:

- **Emil von Behring (German, 1854–1917)**, who would win a Nobel Prize in 1901 for developing therapeutic antibodies.
- **Paul Ehrlich (German, 1854–1915)**, who would win a Nobel Prize in 1908 for his work on immunology and therapeutics.
- **Heinrich Hertz (German, 1857–1894)**, who demonstrated electromagnetic waves and laid the foundation for everything from radio to radar.
- **Felix Klein (German, 1849–1925)**, shown in Fig. 10.10, who introduced a number of innovations in mathematics but even more importantly built up the University of Göttingen as a major research and educational center with direct assistance from Althoff.
- **Robert Koch (German, 1843–1910)**, shown in Fig. 10.10, who would win a Nobel Prize in 1905 for studying bacterial infections.
- **Walther Nernst (German, 1864–1941)**, who would win a Nobel Prize in 1920 for physical chemistry.
- **Max Planck (German, 1858–1947)**, shown in Fig. 10.10, who would win a Nobel Prize in 1918 for quantum physics, handled all theoretical physics papers in the major physics journal, *Annalen der Physik*, almost single-handedly from 1895 until 1943, and educated and supported a large number of young scientists including Max Abraham, Walther Bothe, Gustav Hertz, Erich Kretschmann, Max von Laue, Julius Lilienfeld, Walther Meissner, Lise Meitner, Fritz Reiche, Moritz Schlick, and Walter Schottky.
- **Ludwig Prandtl (German, 1875–1953)**, shown in Fig. 10.10, who pioneered mathematical aerodynamics and was also a strong political advocate for the same agenda as Althoff.
- **Arnold Sommerfeld (German, 1868–1951)**, shown in Fig. 10.11, who pioneered much of quantum and solid state physics, and who found, mentored, and supported a vast number of talented young scientists including Karl Bechert, Hans Bethe, Peter Debye, Paul Epstein, Paul Ewald, Herbert Fröhlich, Erwin Fues, Ernst Guillemin, Werner Heisenberg, Walter Heitler, Helmut Hönl, Ludwig Hopf, Walther Kossel, Adolf Kratzer, Herbert Krömer, Alfred Landé, Otto Laporte, Wilhelm Lenz, Wolfgang Pauli, Linus Pauling, Rudolf Peierls, Walter Rogowski, Werner Romberg, Rudolf Seeliger, Heinrich Welker, and Gregor Wentzel.

Wilhelm Ohnesorge
Ernst Heinkel

Figure 10.11: More examples of scientific “enlightened despots” who had a very large impact on the German-speaking world: Arnold Sommerfeld, Carl Duisberg, Wilhelm Ohnesorge, and Ernst Heinkel.

As just one example of the enormous impact of Althoff on individual careers, Paul Ehrlich wrote the following note of gratitude to Althoff on 27 July 1907 [Sachse 1928, p. 235]:

> Ich persönlich danke Ihnen meine ganze Karriere und die Möglichkeit, meine Ideen nutzbringend auszugestalten. Als Assistent herumgeschubst, in die engsten Verhältnisse eingezwängt—von der Universität gänzlich ignoriert—kam ich mir ziemlich unnütz vor. Ich habe nie einen Ruf an die kleinste Stelle erhalten und galt als Mensch ohne Fach, d. h. vollkommen unverwertbar. Wenn Sie da nicht mit starker Hand und genialer Initiative für mich eingetreten wären, wenn Sie mir nicht mit rastlosem Eifer und gütiger Freundschaft die Arbeitsmöglichkeiten zurechtgemacht hätten, unter denen ich mich entwickeln konnte, wäre ich vollkommen brachgelegt gewesen.

> I personally thank you for my entire career and the opportunity to make my ideas useful. As an assistant pushed around, squeezed into the tightest conditions—completely ignored by the university—I felt rather useless. I never received a call to the least position and was considered a person without specialty, in other words completely unusable. If you had not been there for me with a strong hand and ingenious initiative, if you had not showered me through untiring zeal and benevolent friendship with employment opportunities, through which I could develop myself, I would have been totally broken down.

In 1911, the German sociologist and political economist Max Weber summed up both the enlightened and the despotic aspects of Althoff's approach to scientific management, as well as their legacy in the German-speaking world [Baumgart 1980, p. 9]:

> Es ist sehr schwierig über diesen Mann zu sprechen. Er war wirklich nicht nur ein guter Mensch im spezifischen Sinne des Wortes, sondern er war ein Mann von sehr weiten Gesichtspunkten,... dem die deutschen Universitäten Dinge verdanken, die in gewissem Sinne unsterblich sind... Und in personaler Hinsicht kann nicht nachdrücklich genug betont werden...: Nepotismus gab es unter ihm nicht... Aber... die Mittel, mit welchen die preußische Unterrichtsverwaltung arbeitete, waren die denkbar rücksichtslosesten. ... Der Einfluss des Althoffschen Systems hat direct korrumpierend gewirkt.

> It is very difficult to talk about this man. He really was not just a good man in the specific sense of the word, but he was a man with a very broad point of view, ... to whom the German universities owe things that are unending in a sense... And in personal terms it cannot be stressed strongly enough...: there was no nepotism under him... But... the means by which the Prussian educational administration worked were the most ruthless conceivable. ... The influence of Althoff's system has had a directly corrupting effect.

Althoff also played a critical role in establishing several whole research institutions, including the many Kaiser Wilhelm Institutes (which had an enormous impact on all scientific fields in the following decades, and became the Max Planck Institutes after World War II), the Koch Institute for Infectious Diseases (Berlin), the Institute for Serum Research and Therapy or the Georg-Speyer-Haus (Frankfurt), the Institute of Hygiene and Experimental Therapy (Marburg), the International Association Against Tuberculosis, the University of Münster, the Royal Academy in Poznan, the Gdansk Institute of Technology, the Wroclaw Institute of Technology, and the early plans of what would become the Friedrich Loeffler Institute on Riems island after Althoff's death. Likewise, Althoff greatly expanded several existing institutions, including the University of Berlin, the University of Göttingen, and the Berlin Charité research hospital.

As already noted, many of Althoff's scientific protégés, such as Felix Klein, Max Planck, Ludwig Prandtl, and Arnold Sommerfeld, became enlightened despots themselves, greatly advancing different parts of the German-speaking research world (Figs. 10.10–10.11). As covered below, Friedrich Schmidt-Ott was arguably Althoff's most powerful and most influential protégé, even though he was not a scientist (just as Althoff was not a scientist). Thus Althoff's protégés, and the people whom they supported, exponentially multiplied the effect that Althoff had on the German-speaking world.

Friedrich Schmidt-Ott (German, 1860–1956), shown in Fig. 10.9, was Friedrich Althoff's assistant for many years. When Althoff retired and then died, Schmidt-Ott continued to play the same role that Althoff had, through his positions in several science funding organizations. Schmidt-Ott was the Prussian minister of culture (like Althoff before him), president of the Emergency Association of German Science (Notgemeinschaft der Deutschen Wissenschaft, which he helped to establish in 1920), a vice president and member of the advisory boards of the Kaiser Wilhelm Institutes, and chairman of the Donor Federation of the Emergency Association of German Science (Stifterverband der Notgemeinschaft der Deutschen Wissenschaft, which he also helped to create in 1920).

In an interview with István Hargittai, the DNA pioneer Erwin Chargaff (see p. 93) recounted his interaction with Schmidt-Ott. The episode also serves as an excellent example of how the enlightened despots made funding decisions [István Hargittai 2000–2006, Vol. I, p. 24]:

> *[Interviewer] How did they decide who should get support?*
>
> It was very different. They didn't believe in peer review, and neither do I, for that matter. I can tell you about my case. I was told by Martin Hahn that if I wanted to supplement what the Department paid me, I should make an application to the Deutsche Notgemeinschaft for a grant. A certain amount would then be branched off to supplement my salary, and I could buy chemicals, etc. I made an application and got an invitation in writing to see, and this was incredible, the chief of the Notgemeinschaft who wasn't even a scientist. His name was Schmidt-Ott and he was an orientalist. I was let into the office of His Excellency, and he made me sit down and we started talking about what books I was reading at that time. Then he asked me about my plans and I told him that I had written a proposal about my work on polysaccharides of tubercle bacilli and so on. He asked me what was a polysaccharide. I explained and then he said that I would soon hear from him. Three days later I had the grant. This is not as stupid as it may seem. If you get the right people they don't have to spend too much time on it. I find it silly when they call this proposal valuable and the other proposal not valuable. Most proposals are half so and half so because one doesn't know yet, and if it is good it may still not work. So the peer reviews are completely useless except that they grow into old boys networks. I think the most important is to get the general behavior, the general way of thinking of the person rather than to decide that this is a marvelous problem. They are not marvelous except in lucky hands, in very gifted hands. The hands you can't look at in a proposal.

As illustrated by the following examples, other enlightened scientific despots at that time or later appear to have arisen independently of Althoff, again perhaps because of the generally autocratic government style that was pervasive in that region at that time.

Carl Duisberg (German, 1861–1935), shown in Fig. 10.11, ran one of the first large corporate research programs at Bayer and then engineered the creation of the even larger research and development entity, I.G. Farben, by the merger of Bayer with other companies, ultimately resulting in a whole range of innovative medical, chemical, and materials science products. Historian Ulrich Marsch described the impact of Duisberg's strategy [Marsch 1994a, pp. 56–59]:

> When IG Farben was founded in late 1925 the organization of research was not a major issue. Decentralization of research had been practiced by all constituent companies for more than forty years was thus simply continued. [...]
>
> IG was under control of the technical men: members of the Managing Board and the key Technical Committee. A decisive element in the technical structure of IG became the TEA-Büro, though it was never meant to play that role. Here the scientific and technical directors of the works and laboratories met and proposed via the Technical Committee, TEA, new projects or investment. We have also seen that the decision to place a product on the market was made by scientifically trained middle managers (heads of works laboratories, and technical commissions) after the successful completion of tests and application processes. Unlike DuPont, where salesmen were more involved in future products, at IG the scientists were in charge.
>
> There are even more differences between IG and DuPont that are worth noting. As it was put recently, IG had a much "leaner" management with fewer hierarchies between production and administration, and especially a closer contact between researchers, research directors and the top management. The project and budget system and the absence of a rigid controlling system of the laboratories' expenses exemplify the relative autonomy of the scientific men inside IG Farben. Also, the existence of independently working individual scientists within the organized research work of the large laboratories and the close contact between those scientists and the research directors shows the importance of the individual scientist right into the 20th century and casts doubts on the absolute priority of team work stressed today. [...]
>
> The argument that the absence of a centralized Research and Development Department at IG caused strategical disadvantages is somewhat misleading: all major German chemical firms before 1925 had grown that way. Putting the main focus only on the Main Laboratories means telling only a small part of the whole story. It was the close connection between research and production and the parallel existence of centralized scientific laboratories, scientific works laboratories, product works laboratories and many technical stations that built the basis for the success of the German chemical companies for more than forty years. IG continued this tradition successfully. The innovative process happened in many locations, and the more research and application sites there were, the more likely was invention and innovation.

Wilhelm Ohnesorge (German, 1872–1962), shown in Fig. 10.11, studied physics as a university student yet made a career in the German Post Office (Reichspost). From that position, he single-handedly turned the Post Office into a strong sponsor of a wide variety of innovative research on particle accelerators, isotope separation, fission reactions and explosives, radar, television, electron microscopy, robotics, and other projects. Ohnesorge gave strong financial and political support to scientists including Manfred von Ardenne, Siegfried Flügge, and others. Helmut Joachim Fischer, a physics Ph.D. who was highly placed in the SS, gave a good description of Ohnesorge [Helmut Fischer 1988, pp. 133–134]:

Die Reichspost hatte von jeher technische Aufgaben zu bewältigen und stützte sich daher auf umfangreiche Forschungs- und Entwicklungsarbeiten auf dem Gebiet der Fernmeldetechnik und anderer für das Postwesen nützlichen Techniken. Dafür gab es in Darmstadt ausgedehnte Laboratorien neben dem Reichspostzentralamt in Berlin-Tempelhof, dessen Präsident Prof. Gladenbeck war.	The Reichspost has always had to cope with technical tasks and therefore relied on extensive research and development work in the field of telecommunications technology and other technologies useful for the postal system. To this end, Darmstadt had extensive laboratories alongside the Reichspost central office in Berlin-Tempelhof, whose president was Prof. Gladenbeck.
Diesen vorgegebenen Rahmen sprengte der ehrgeizige Reichspostminister Ohnesorge. Er hatte einst bei Lenard Physik studiert und interessierte sich allgemeiner für wehrwissenschaftliche Probleme und schaltete zu ihrer Bearbeitung Mitarbeiter und Einrichtungen der Reichspost ein. Reichspost-Forschungsanstalten entstanden in der Nachbarschaft von Berlin in Kleinmachnow und in Miersdorf. Sie betrieben naturwissenschaftliche Grundlagenforschung, und das Institut in Miersdorf unter Dr. Banneitz befaßte sich sogar ernsthaft mit Kernphysik, wobei die Herstellung einer Atombombe angestrebt wurde. Überdies spannte Ohnesorge, der über genügend Geldmittel verfügen konnte und auf die Hilfe des Reichsforschungsrates nicht angewiesen war, auch Hochschulinstitute (wie etwa in Heidelberg) und zudem den tüchtigen Privatforscher Manfred von Ardenne mit seinem eigenen Laboratorium in Berlin-Lichterfelde für seine Forschungsziele ein. Sowohl in Miersdorf als auch im Institut Ardennes begann der Bau je einer 60-Millionen-Volt-Zyklotron-Anlage und von Hochspannungsgeräten, die mit einer Million Volt arbeiten.	The ambitious Reichspost Minister Ohnesorge went beyond this rigid framework. He had once studied physics with Lenard and was more interested in military science problems in general and called in employees and institutions of the Reichspost to deal with them. Reichspost research institutes were established in the vicinity of Berlin in Kleinmachnow and in Miersdorf. They carried out basic scientific research, and the institute in Miersdorf under Dr. Banneitz was even seriously concerned with nuclear physics, with the aim of producing an atomic bomb. In addition, Ohnesorge, who had sufficient funds at his disposal and was not dependent on the help of the Reich Research Council, also employed university institutes (such as Heidelberg) and the capable private researcher Manfred von Ardenne with his own laboratory in Berlin-Lichterfelde for his research goals. Both in Miersdorf and at Ardenne's Institute, construction began on 60 million volt cyclotron facilities and on high-voltage equipment operating at one million volts.

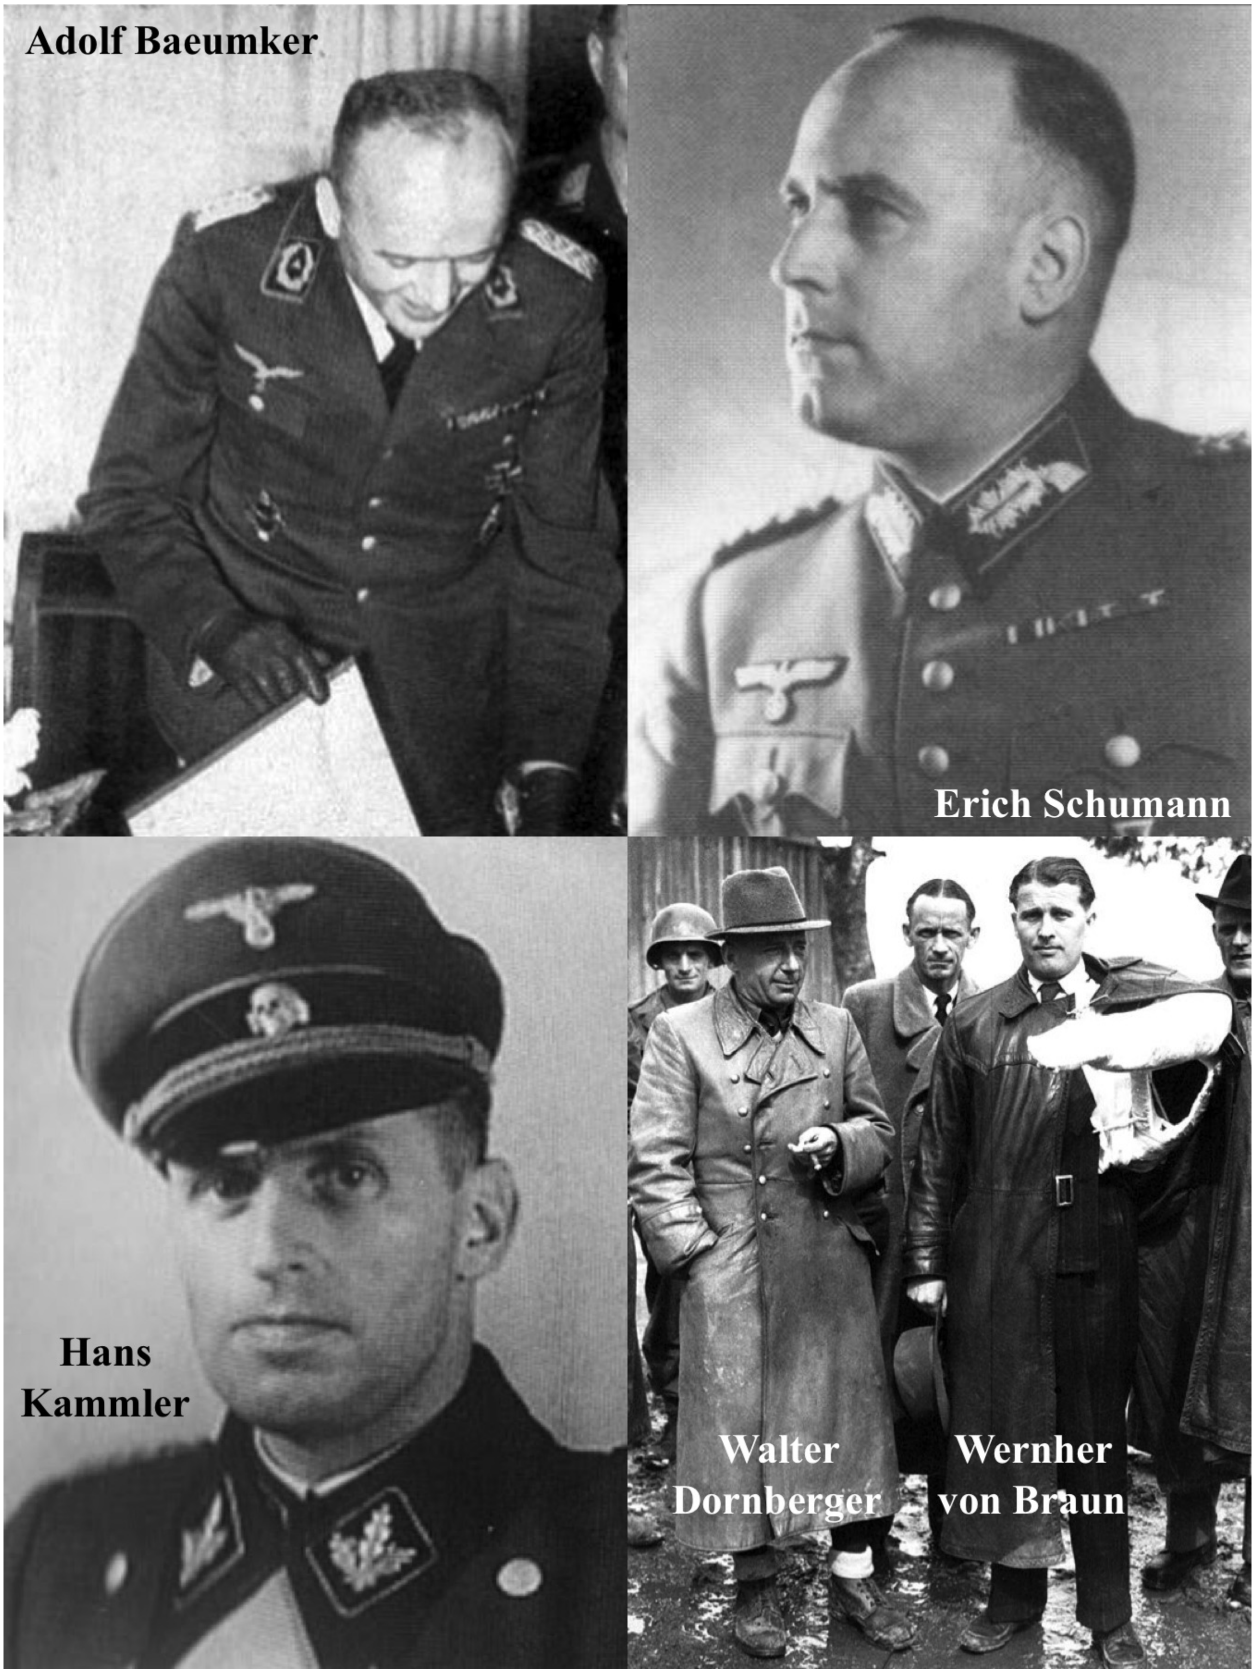
Ernst Heinkel (German, 1888–1958), shown in Fig. 10.11, was the formidable founder and manager of the Heinkel Flugzeugwerke aircraft company. He personally recruited, directly financed, and politically defended a number of revolutionary creators and their creations, including the development of turbojet engines by Hans von Ohain, Herbert Wagner's research group, and others; the development of rocket planes by Wernher von Braun, Hellmuth Walter, and others; the development of advanced airfoils and jet aircraft by Siegfried and Walter Günter and others; the first practical ejection seats in aircraft; and other projects. Heinkel described his recruitment and support of young scientists and engineers [Heinkel 1956, pp. 210–231]:

> In November, 1935, I met a young man, today famous, but who at that time was unknown. Wernher von Braun, since his first year at college, had been passionately interested in the development of rockets.
>
> When I met him he was testing a primitive rocket engine on the artillery testing grounds at Kummersdorf. [...]
>
> "With this rocket engine," von Braun said to me, "one should be able to propel a plane." [...]
>
> This was the beginning of my close association with von Braun. I drove to Kummersdorf, where he was working with some of his friends in a dreary shed. After our first discussions, I delivered to him the fuselage of the He 112 fighter, complete with undercarriage. I also lent him a team of riggers headed by my engineer, Walter Künzel. At the beginning of 1936 this team moved to Kummersdorf. [...]
>
> While these first bench experiments in Kummersdorf—a matter of life or death for those who took part, particularly for the pilot—were being carried out, I received a letter from Professor Pohl, head of the Science Institute at the University of Göttingen. He informed me that he had an assistant, Pabst von Ohain, who was working on a new power unit for airplanes, which did not use a propeller. Von Ohain was very capable. He had already spent his private means carrying out experiments, but now he had reached the end of his resources. Pohl assured me that the young man's ideas were scientifically sound and that it should be possible to put them into practice.
>
> I wrote at once and arranged for von Ohain to come to Warnemünde on March seventeenth. He turned out to be a very likeable young man, scarcely twenty-four years old, a brilliant scientist obviously filled with a burning faith in his idea. He admitted that he as a pure theoretician, and needed both technicians and money to realize his theories. His theories corresponded to what I have already outlined about turbine or jet propulsion, and were primarily concerned with the type of engine that was later known as a centrifugal jet unit.
>
> I hired von Ohain at once, together with a technician named Hahn who had been his assistant in Göttingen. I pledged both of them to utmost secrecy. The same was true for the Günter brothers and Schwärzler, whom I now took into my confidence. Within a month I had a special shed built in Marienehe, completely cut off from the rest of the factory. No one had access to it apart from those directly engaged in the work. I placed this shed at the disposal of Ohain and Hahn.

> When Wagner's jet unit group first approached the Ministry they were told that all preliminary experiments and experiences must be turned over to an aircraft engine works, which alone could guarantee the necessary "practical application." The result was that most of Wagner's people quit Junkers and returned to the Aviation Institute in Berlin. Some of them, however, had apparently heard of the progress of my own work. They applied for jobs in my factory and I took them on. [...]
>
> While the group under Ohain devoted its main attention to an engine with a centrifugal compressor similar to the He S 3, I decided to form a new group, partly composed of the new technicians but under the general direction of Ohain, to undertake the construction of an engine with an axial compressor. I meant to pursue two parallel lines of development in order to determine which one produced the best results. [...]
>
> The second engine group, however, also had its eye on other types of propulsion unit, particularly the mixed type which, designated as a "compound engine," [turboprops or turbofans] is today fairly common in America for large airplanes of moderate speed.
>
> This resulted in the formation of several special divisions which concerned themselves with the development and testing of the most diverse new kinds of engines. The divisions had such code designations as TL (Turbo-jet; *Turbine-Luftstrahl*); STL (ramjet-turbo-jet; *Staurohr-Turbine-Luftstrahl*); or ML (reciprocating engine and jet; *Motor-Luftstrahl*). [...] For the time being I went along with this trend, because nothing can be so instructive as a number of parallel developments. [...]
>
> ...at that stage of development in a new field it was not possible to adopt certain types and write off others, as could be done later. The capable scientists and designers now working together under me already knew the snags to be avoided—for our parallel developments embraced nearly the entire field.
>
> This apparently was also Udet's opinion when finally, at the end of 1939, I won him over to the idea that this new development was of the utmost importance. [...] Udet also found a way to protect me from Mauch's and Schelp's obstructionist tactics...

Adolf Baeumker (German, 1891–1976) ran research programs for the Air Force (Luftwaffe) from a series of increasingly elevated positions during the period 1924–1945 (Fig. 10.12). After the war, he advised both the United States and West Germany on Air Force research programs until the 1960s, proving how widely his talent as a research manager was recognized. Aerospace historian Ernst Hirschel gave a brief overview of Baeumker's importance [Hirschel et al. 2004, p. 72]:

> Baeumker may be considered as one of the first "Science Managers" in Germany. He established the "Aeronautical Research Council" ("Forschungsrat für Luftfahrt"), initiated by Prandtl and von Kármán, to promote the exchange between research and industry. [...] 1935 he created the "Lilienthal-Society" [...] and he founded in 1936 the "German Academy for Aeronautical Research" ("Deutsche Akademie der Luftfahrtforschung"). [...] 1945 he goes to the USA, where he worked for various military offices. 1958 he is transferred to the European Headquarter of the American Air Force (USAFE) in Wiesbaden to work for the cooperation in research and development between the Federal Republic of Germany and the USA. He advises in the sixties German and American head offices in Bonn, among other things, also to unite non-university German aerospace research.



Adolf Baeumker
Erich Schumann
Hans Kammler
Walter Dornberger
Wernher von Braun

Figure 10.12: More examples of scientific "enlightened despots" who had a very large impact on the German-speaking world: Adolf Baeumker, Erich Schumann, Hans Kammler, and Wernher von Braun and Walter Dornberger.

Erich Schumann (German, 1898–1985), shown in Fig. 10.12, was a physics professor at the University of Berlin, chief physicist of the Army Ordnance Office (Heereswaffenamt), and member of the Reich Research Council (Reichsforschungsrat). In those positions, he led or was directly involved in research on rockets (he was Wernher von Braun's doctoral dissertation advisor), armor-penetrating shaped charge conventional explosives, fission reactions and explosives, fusion reactions and explosives, biological weapons, quite likely chemical weapons, and other areas [Nagel 2012a]. Schumann recruited scientists for all of these areas and supported them both financially and politically. Ultimately all of these technologies that he helped to develop became critical components of Cold War military arsenals and strategies for the United States, Soviet Union, and other countries. The historian Rainer Karlsch gave a thumbnail sketch of Schumann, the many hats that he wore, and the many ways that various other people perceived him [Karlsch 2005, pp. 31–32]:

Die Forschungsstelle des HWA ging bei allen Projekten vom Grundsatz aus, die vorhandenen Strukturen, dazu gehörten Universitäten, außeruniversitäre Forschungseinrichtungen und Firmen, in ihrem Sinne zu nutzen und zu steuern. Im HWA selbst wurden nur Forschungen angesiedelt, die aufgrund ihrer militärischen Bedeutung nicht "außer Haus" gegeben werden konnten.	In all its projects, the Army Ordnance Office's research center was based on the principle of using and controlling the existing structures, including universities, non-university research institutions and companies, in their interests. In the Army Ordnance Office itself the only research that was conducted was that which could not be sent "out of the house" due to its military implications.
Leiter der Forschungsabteilung des HWA war seit 1934 Ministerial-dirigent Professor Erich Schumann. Er war in kurzer Zeit zu einem Multifunktionär aufgestiegen. Seit 1929 leitete er die Abteilung für Akustik am Physikalischen Institut der Berliner Universität und lehrte experimentelle und theoretische Physik. Zum Direktor des neu gegründeten II. Physikalischen Instituts wurde er 1934 ernannt. Sein Interesse galt vor allem der Sprengstoffphysik. Gegenüber den Hochschulkreisen war Schumann stets bemüht, seine Rückendeckung durch die Wehrmacht zu betonen. Seine Einstufung als Ministerial-dirigent entsprach beim Heer etwa dem Rang eines Generalmajors. Nicht wenigen seiner Gesprächspartner blieb er als "General" in Erinnerung, beeindruckend in Uniform und durch sein temperamentvolles und dynamisches Auftreten.	Since 1934 Professor Erich Schumann had been head of the research department of the Army Ordnance Office. Within a short time he had become a multifunctional official. From 1929 he headed the Department of Acoustics at the Physics Institute of Berlin University and taught experimental and theoretical physics. He was named director of the newly founded Second Physics Institute in 1934. His main interest was in explosives physics. Schumann was always anxious to emphasize his support by the military to the university circles. His classification as a ministerial official was roughly equivalent to that of a major general in the army. Not a few of his interlocutors remembered him as "General," impressive in uniform and with his spirited and dynamic appearance.

> Über Schumanns Qualitäten als Wissenschaftsorganisator gingen die Meinungen der Zeitgenossen weit auseinander. Die einen sahen in ihm einen fähigen Wissenschaftler und großen Förderer der Kampfstoffforschung und Sprengstoffphysik, die anderen nannten ihn einen Scharlatan, der sich in den Dienst von windigen Projekten stellte. [...] Doch Schumann auf die Rolle eines eitlen Machtmenschen zu reduzieren, hieße seine wissenschaftliche Kompetenz und sein organisatorisches Talent zu unterschätzen.

> The opinions of his contemporaries differed widely about Schumann's qualities as a scientific organizer. Some saw him as a capable scientist and great supporter of warfare research and explosives physics; others called him a charlatan who was at the service of windy projects. [...] But to reduce Schumann to the role of a vain power man would be to underestimate his scientific competence and organizational talent.

Hans Kammler (German, 1901–?), shown in Fig. 10.12, is worthy of special mention [Agoston 1985]. He had a doctoral degree in engineering and rose to the level of General (Obergruppenführer) in the SS. Over the course of World War II, Kammler gained control over more and more of the military's advanced R&D programs. By the end of the war he controlled virtually all of the major programs—rockets, missiles, jets, nuclear technology, directed energy technologies, etc.—and then he mysteriously vanished. New evidence proves that he was secretly captured and interrogated by the United States (pp. 4931–4959). It is unclear how much Kammler contributed to the success of all of those programs versus how much he simply took over already successful programs, but at a minimum it is clear that he had formidable political skills and a strong taste for very innovative, high-impact research. Of course, he also ordered or assisted in the murder of large numbers of people, so he is certainly not a role model. Helmut Fischer, a physics Ph.D. who was highly placed in the SS's security office, succinctly described Kammler [Helmut Fischer 1988, p. 64]:

> Eine besondere Rolle spielte dabei der Leiter der Gruppe C des WVHA [Wirtschafts- und Verwaltungs-Hauptamt], SS-Gruppenführer Hans Kammler. Anlässlich der Erstellung von Bauten in Peenemünde, wo die Vergeltungswaffe V 2 geschaffen wurde, kam Kammler mit den Verantwortlichen für die V-Waffen in Berührung. Er machte sich bald unentbehrlich, riss immer mehr Zuständigkeiten an sich und wurde schliesslich zum massgeblichen Mann für die Fertigung der Vergeltungswaffen. Aber damit nicht genug! Der ehrgeizige Kammler schaltete sich auch in die Forschungs- und Entwicklungsarbeiten zur Konstruktion neuartiger Waffen ein. Dazu erlangte Kammler auch die Befehlsgewalt über die Sondereinheiten der Wehrmacht, die für den Fronteinsatz der V-Waffen aufgestellt worden waren. Kammlers Machtstellung wurde schliesslich so stark, dass Speer als Reichsminister für Rüstung und Kriegsproduktion um seine Stellung fürchsten musste.

> A special role was played by the leader of Group C of the WVHA [Economic and Administrative Main Office], SS-Gruppenführer Hans Kammler. On the occasion of the construction of buildings in Peenemünde, where the reprisal weapon V-2 was created, Kammler came into contact with those responsible for the V-weapons. He soon made himself indispensable, increasingly took over responsibilities and eventually became the key man for the production of retaliatory weapons. But that is not all! The ambitious Kammler also turned to the research and development work on the construction of novel weapons. Kammler also gained command of the special forces of the Armed Forces, which had been set up for the front line of the V-weapons. Kammler's position of power was finally so strong that Speer had to worry about his position as Minister of Armaments and War Production.

Wernher von Braun (German, 1912–1977), Walter Dornberger (German, 1895–1980), and their military and government sponsors provided very strong, driven, focused, long-term support for the development of large liquid propellant rockets; see Fig. 10.12. Boris Chertok, a leader of the Soviet rocket programs from the time they acquired experts and technology in Germany in 1945, described von Braun's management style [Chertok 2005–2012, Vol. 1, pp. 305–306]:

> Von Braun's story is no longer novel, thanks to numerous publications by American, German, and Soviet researchers, and even television documentaries. For that reason I will not cram my memoirs with yet another version of von Braun's biography. Gröttrup said that one of von Braun's very good traits was his striving to attract the most talented people. In doing so, he did not take age into account, and he was not afraid of competition.
>
> Von Braun had been named technical director of Peenemünde-Ost at the age of twenty-five! For Germans this was quite unusual. But this shows how highly they valued his talent, initiative, and rare intuition. According to Gröttrup, von Braun was very attentive to senior, experienced specialists. He made fundamental decisions after having first gathered and listened to diverse opinions. There was no voting; von Braun always had the last word, but he managed not to offend the other staff. In spite of his youth, his authority was not called into question.
>
> Fifty years after this assessment of von Braun's management style, I met with an American engineer named Jerry Clubb, who was a participant in the Apollo-Saturn lunar program, which had been directed by the no longer twenty-five but fifty-five-year-old, world-renowned creator of the first long-range ballistic missiles. The American talked about von Braun's working style in the United States in the same way that I had heard Gröttrup describe it in 1945 over a cup of coffee with whipped cream. [...]
>
> Von Braun had been valued and trusted by Dornberger and the higher military leadership of the infantry forces who had financed the construction of Peenemünde. He did not have to fear intrigue against himself, and he was able to work confidently as the technical director. Dornberger, who had become a general at Peenemünde, had always shielded von Braun. They were a powerful duo.
>
> In spite of various nuances in political views, the main leadership staff had worked rather harmoniously and very selflessly.

Thus the German-speaking research world appears to have greatly benefited from a number of enlightened despots during the nineteenth and early twentieth centuries. As shown in Section 11.2.6, this same sort of enlightened despot approach to identifying and supporting scientific innovators and innovations was also employed by very successful German-inspired U.S. research and development programs during their heyday in the 1940s through 1960s. Innovation experts have argued for bringing back this sort of management approach to improve the modern innovation system, either as an alternative to or as a supplement for the more conservative modern peer-review/consensus-based methods [e.g., p. 2248; Azoulay et al. 2019; Braben 2004, 2008, 2014].

10.2.7 Systems Analysis

One factor in the success of the earlier German-speaking world appears to have been widespread explicit or implicit application of systems analysis. As shown in Fig. 10.13, systems analysis is a top-down approach to:

- First identify a whole range of important problems.
- Then choose the most important problem that can be addressed with the available resources.
- Next enumerate all potential types of solutions to that problem, systematically covering all possibilities and demonstrating that they form a complete set with no omissions.
- Then consider which potential solutions are ruled in or out by laws of nature or by their inherent disadvantages or advantages.
- Finally focus on pursuing the most promising solutions for the most important problems.

This systems analysis mindset appears to have been deeply ingrained in German-speaking culture and can be traced back at least as far as Wilhelm von Humboldt at the beginning of the nineteenth century (see for example the quotes on p. 1965). It was most clearly and fully articulated by Fritz Zwicky (1898–1974), a Swiss physicist who emigrated to the United States and who referred to the systems analysis method as the “morphological approach” [Zwicky 1969, pp. 36–37, 105–108]:

> It has often been stated that it is no longer possible today to know all or even several fields of science well, let alone to contribute materially to their advancement. This erroneous belief, as well as the rather astounding fact that among men of research there are but a very few who can make discoveries and inventions in widely separate fields, proves that the majority of them are either quite incapable of thinking morphologically or they have not yet learned or been taught to view the world as a whole. Contrary to the currently entrenched idea that universality of knowledge is a thing of the past, those who can visualize the true world image will nevertheless be capable of successfully doing research on many diverse subjects. They will also succeed in producing discoveries and inventions that have escaped the specialists in all domains of human activity because such specialists lack that type of universal outlook which, as I hope to show, automatically leads to the recognition of entirely new insights. [...]
>
> (a) Morphological research is totality research, which in a completely unbiased way attempts to derive all the solutions of any given problem.
>
> (b) The morphological approach has developed its own characteristic procedures, such as the method of the morphological box which will be explained and applied in this chapter.
>
> (c) The morphological approach gives us the maximum guarantee that no circumstance is overlooked that might be of importance for the satisfactory accomplishment of any task before us. [...]

> (h) The morphological approach enables us to systematize our inventiveness. It allows us to make discoveries and inventions methodically, and in some cases almost automatically. Without that, we are forced to resort to haphazard procedures of trial and error.
>
> (i) Expressing it pointedly, we may say that the morphologist is a professional genius. In other words, it is his profession to be a genius who is capable of pursuing original research and making discoveries and inventions in all fields of human endeavour. Those who are commonly thought to be geniuses are actually amateurs whose accomplishments in restricted fields are more or less accidental and bear the mark of dilettantism. [...]
>
> For the construction of any morphological box and for the subsequent evaluation of the information that may be contained in it we proceed as follows:
>
> First Step. The problem to be solved must be very concisely formulated.
>
> Second Step. All of the parameters that might be of importance for the solution of the given problem must be localized and analyzed.
>
> Third Step. The morphological box or multidimensional matrix, which contains all of the potential solutions of the given problem, is constructed.
>
> Fourth Step. All the solutions contained in the morphological box are closely scrutinized and evaluated with respect to the purposes that are to be achieved.
>
> Fifth Step. The optimally suitable solutions are being selected and are practically applied, provided the necessary means are available. This reduction to practice requires in general a supplemental morphological study.

This systems approach that was described so explicitly by Zwicky appears implicitly throughout the German-speaking world, both in how the creators selected important problems to address (such as those summarized in Chapters 2–9), and also in how the creators exhaustively explored all viable solutions for those problems (for example a whole range of different types of engines, organic molecules, aerospace vehicles, etc.).

This top-down approach similarly appears to have been the guiding principle for Friedrich Althoff and the other enlightened despots managing the German-speaking world as they decided which creators and creations were the most important to support. For example, as shown on p. 2009 of this chapter, Ernst Heinkel and the engineers working for him used systems analysis to consider all the major types of possible jet engines, and to pursue the most promising ones in parallel in order to determine which ones would be best.

As another example, Donald Putt's postwar U.S. investigations into wartime German missile research reported how systems analysis had been thoroughly exploited to consider all possibilities in the missile programs [Putt 1946a]:

> Many of Germany's research laboratories and several large commercial firms concentrated on this field of endeavor. This tremendous effort resulted in 138 guided missiles and assorted devices, including their modifications. These were of types wholly unknown

> to laymen in the United States. At the outbreak of the war some of these were strictly "out of this world"—to use a current phrase. In addition, German scientists had developed other equipment of a type we had considered impracticable, such as the ram jet.
>
> The stupendous effort in basic research expended by the Germans in the guided missile field was designed to cover the complete field of potentialities for such weapons. The losses incurred in Germany by heavy bomber raids can in no way be charged to lack of preliminary research on missiles. Weapons of this category were divided into the following classifications:
>
> A. Ground to air.
>
> B. Air to air.
>
> C. Air to ground.
>
> D. Ground to ground.
>
> E. Underwater to underwater.
>
> F. Underwater to ground.
>
> G. Underwater to air.
>
> Moreover, every known type of remote control and fusing means was exploited. These included radio control, wire control, radar, continuous wave, acoustics, infrared, light beams, and magnetics.
>
> Likewise, all methods of employing jet propulsion for subsonic and supersonic speeds were exploited.

Fritz Zwicky was trained in the earlier German-speaking world, and by the time he wrote his 1969 book (quoted above) in the United States, he sounded disappointed that like-minded innovators had become so scarce in that time and place. They had been much more common in the German-speaking world.

State the broadest problem of interest.

List all possible categories of that problem.

Divide into sub-categories, etc.

Eliminate sub-categories that are not desirable or not possible.

Focus on the most important remaining sub-categories.

Choose an important problem or sub-problem.

List all categories of possible solutions for that problem.

Divide into sub-categories, etc.

Eliminate sub-categories that are not desirable or not possible.

Focus on the most important remaining sub-categories.

Figure 10.13: Systems analysis is a methodical, top-down approach for considering all possible categories of problems of interest, and all possible categories of solutions to those problems, in order to identify and focus on the most promising solutions for the most important problems.

10.2.8 Limited Natural Resources

The German-speaking world had tremendous economic and military needs or aspirations, yet extremely limited natural resources that could be harnessed to fulfill those requirements. This limitation provided an incredibly powerful incentive to create revolutionary new technologies, processes, and materials that could meet those needs with the available resources. That was especially true during wartime, yet even between wars, Germany's lack of resources spurred it to develop synthetic materials to be more economically competitive against foreign industry. As shown in Fig. 10.14, examples of that industrial innovation included synthetic dyes, the Haber-Bosch ammonia production process, synthetic rubber (butadiene or buna), a wide variety of plastics, synthesized explosive molecules, ersatz food ingredients and preservatives, synthetic blood plasma, and the development of biotechnology methods to produce industrial and food products.

Ulrich Wengenroth, a scientific historian at the Deutsches Museum in Munich, described those conditions and the resulting German achievements [Landes et al. 2010, pp. 290–291, 295–296]:

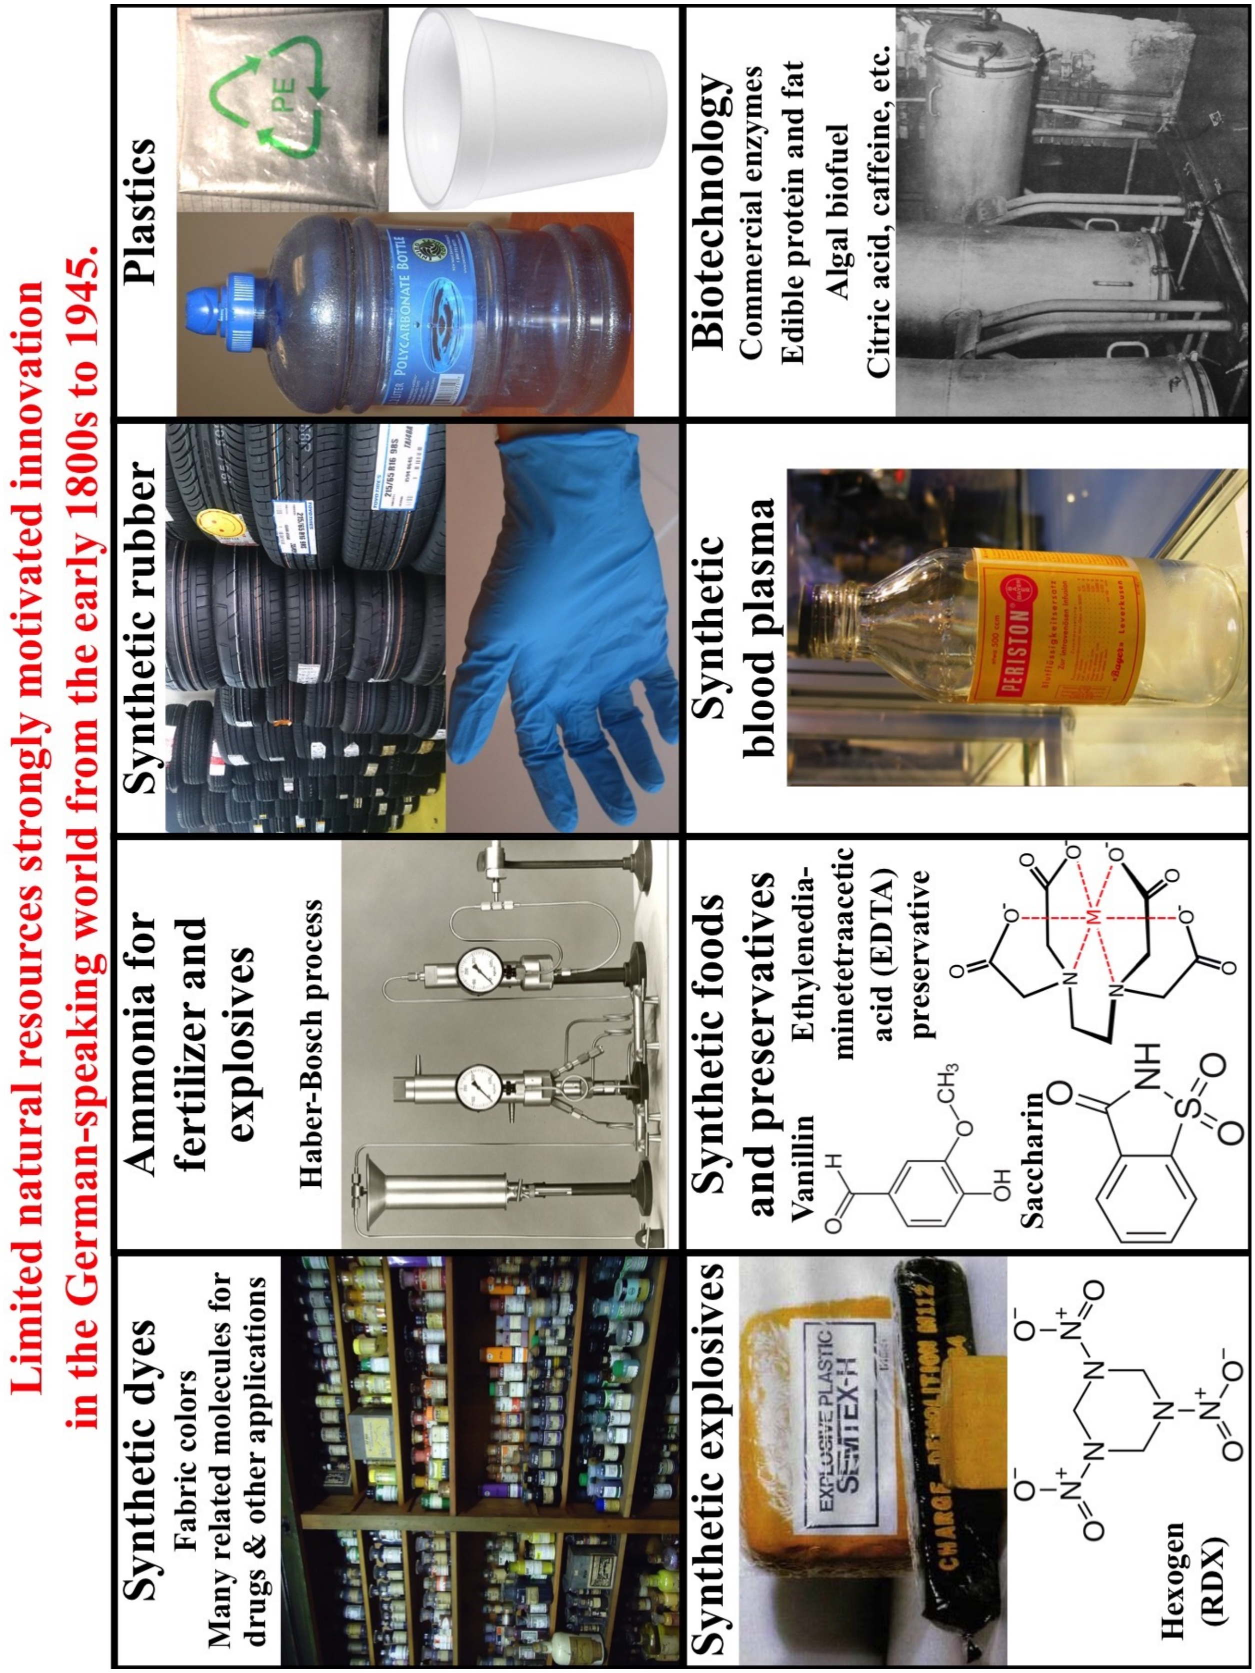
> The showcase of German science-based industry was undoubtedly organic chemistry. From the 1880s until well after World War II German companies held a commanding position in most products based on carbon hydrates, especially when it came to high-value products like pharmaceuticals. [...] The main strategy was always the same: analyze a natural product and then find ways to synthesize it cheaply from the tar derivatives the heavy industries and gasworks would abundantly supply. The overabundant supply of first-rate human capital for industrial research, plus the additional incentive of not having access to natural resources for colonies, created a situation that proved to be immensely fortunate. Only the Swiss chemical industry, also with a good supply of academically trained scientists and no colonies, could match the progress of German organic chemistry. It was one of the first examples after the Industrial Revolution when the absence of natural resources proved to be beneficial. Apart from the availability of highly qualified human capital, the German dyestuffs industry benefited from having hit a treasure trove of potential products, and the most innovative entrepreneurs were smart enough to see and fully utilize that potential. [...]
>
> Germany, which was in no position to safeguard its raw material supplies from a vastly superior British navy, during conflict and in preparing for war turned to processing poor raw materials from its own territory and producing *Ersatz* to overcome supply shortages by second-rate material. Enormous ingeniousness and innovativeness were invested in autarchy technologies[...]
>
> The strength of the German chemical industry in synthesizing chemical compounds that were found in nature or compounds close to them was greatly in demand when the country went into World War I. Just before the war, Fritz Haber had created a process to synthesize ammonia, by this being able to produce nitrogen, which had mostly been imported from South America before the war and, more important, before the blockade by the British navy. Nitrogen was indispensable for both ammunition and fertilizers. [...]

> More on the autarchy line like ammonia synthesis were developments of coal hydrogenation that were begun during World War I and completed with the advent of World War II to produce both gasoline and rubber from domestic coal. The R & D strategy was not so different from chemical synthesis in the prewar years, but it steered away from international markets and considerations of competitiveness of the new production lines. What was quite rational, given the resource poverty of Germany and its inability to break a British naval blockade, slowly turned into a new paradigm of a self-sufficient Germany that would not have to negotiate its way on international markets but could retreat into some self-designed cage. While before World War I chemical synthesis was a way to beat prices and quality of products based on natural resources, after the war and very much in the Nazi years it became a gospel of independence for conducting wars.

A lengthy 1946 *Harper's* magazine article [Charles Walker 1946] listed a number of examples of synthetic materials and processes that had been developed in Germany during World War II and eagerly adopted by the United States after the war; see pp. 75 and 421. Tom Bower summarized the importance of those synthetic materials for Germany during the war, and for the United States after the war [Bower 1987, p. 5]:

> The proof of German technical prowess is overwhelmingly established in the hundreds of reports written by Allied investigators who did not shy from describing the Germans' "astonishing achievement" and "superb invention." It was also established by the very survival of Germany during four years of total war despite the prediction during the first two years of war by British intelligence that the German economy and German industry faced imminent and total collapse. The blockade on essential minerals, chemicals, and petroleum products, it was argued, would cripple weapons production. But the very opposite happened, because German scientists developed an astonishing range of substitutes that not only humiliatingly neutralized the Allied blockade but heralded the dawn of a new scientific era. [...] German scientists had pioneered so many inventions that many Allied experts would complain that their plunder could do no more than scratch the surface.

In contrast, the global system in general and the United States in particular have not felt especially resource-limited over the last several decades, and hence have lacked strong incentives to develop new synthetic materials and processes beyond those that were previously imported from the German-speaking world. With rising concerns about climate change, pollution, overuse of natural resources, and related problems, hopefully that attitude will change, and nations worldwide will have strong incentives to develop revolutionary new materials and processes to minimize the impact on the environment.



Limited natural resources strongly motivated innovation
in the German-speaking world from the early 1800s to 1945.
Synthetic dyes
Fabric colors
Many related molecules for drugs & other applications
Ammonia for fertilizer and explosives
Haber-Bosch process
Synthetic rubber
Plastics
PE
POLYCARBONATE BOTTLE
Synthetic explosives
EXPLOSIVE PLASTIC SEMTEX-H
CHARGE DEMOLITION M112
Hexogen (RDX)
Synthetic foods and preservatives
Vanillin
Saccharin
Ethylenediaminetetraacetic acid (EDTA) preservative
Synthetic blood plasma
PERISTON
Bayer Leverkusen
Biotechnology
Commercial enzymes
Edible protein and fat
Algal biofuel
Citric acid, caffeine, etc.

Figure 10.14: Limited natural resources strongly motivated innovation in the German-speaking world from the early 1800s to 1945.

10.2.9 International Rivalry

Strong competition can forestall a sense of complacency and can therefore spur innovation. From the early 1800s through 1945, the German-speaking world was highly motivated by both fierce military competition and fierce economic competition with several other countries (Fig. 10.15):

- The United Kingdom was a strong scientific rival and industrial competitor throughout that entire time period, and a staunch foe in World War I (1914–1918) and World War II (1939–1945).
- The United States became a strong industrial competitor from the late nineteenth century onward, and was a vigorous and ultimately victorious opponent in World Wars I and II.
- France was a waning scientific powerhouse in the nineteenth and early twentieth centuries, and a military opponent during the Napoleonic Wars (1803–1815), the Franco-Prussian War (1870–1871), and World Wars I and II.
- Russia was a ferocious military opponent during World Wars I and II.
- There was also significant military and economic rivalry among German-speaking states until German unification in 1871, with some rivalry among Germany, Austria, and Switzerland continuing even after that time.

The international rivalries over industrial products and market share were strong drivers for innovations in the German-speaking world, especially in areas such as the chemical industry, electrical machinery, engines and engine-powered vehicles, and optics. Likewise, the military conflicts and active planning during peacetime for the next military conflict emphasized the development and use of new technologies for military purposes—trains to rapidly move troops and supplies, submarines to attack enemy shipping, poison gases to employ against entrenched opponents, aircraft and rockets to reach other countries, and so forth.

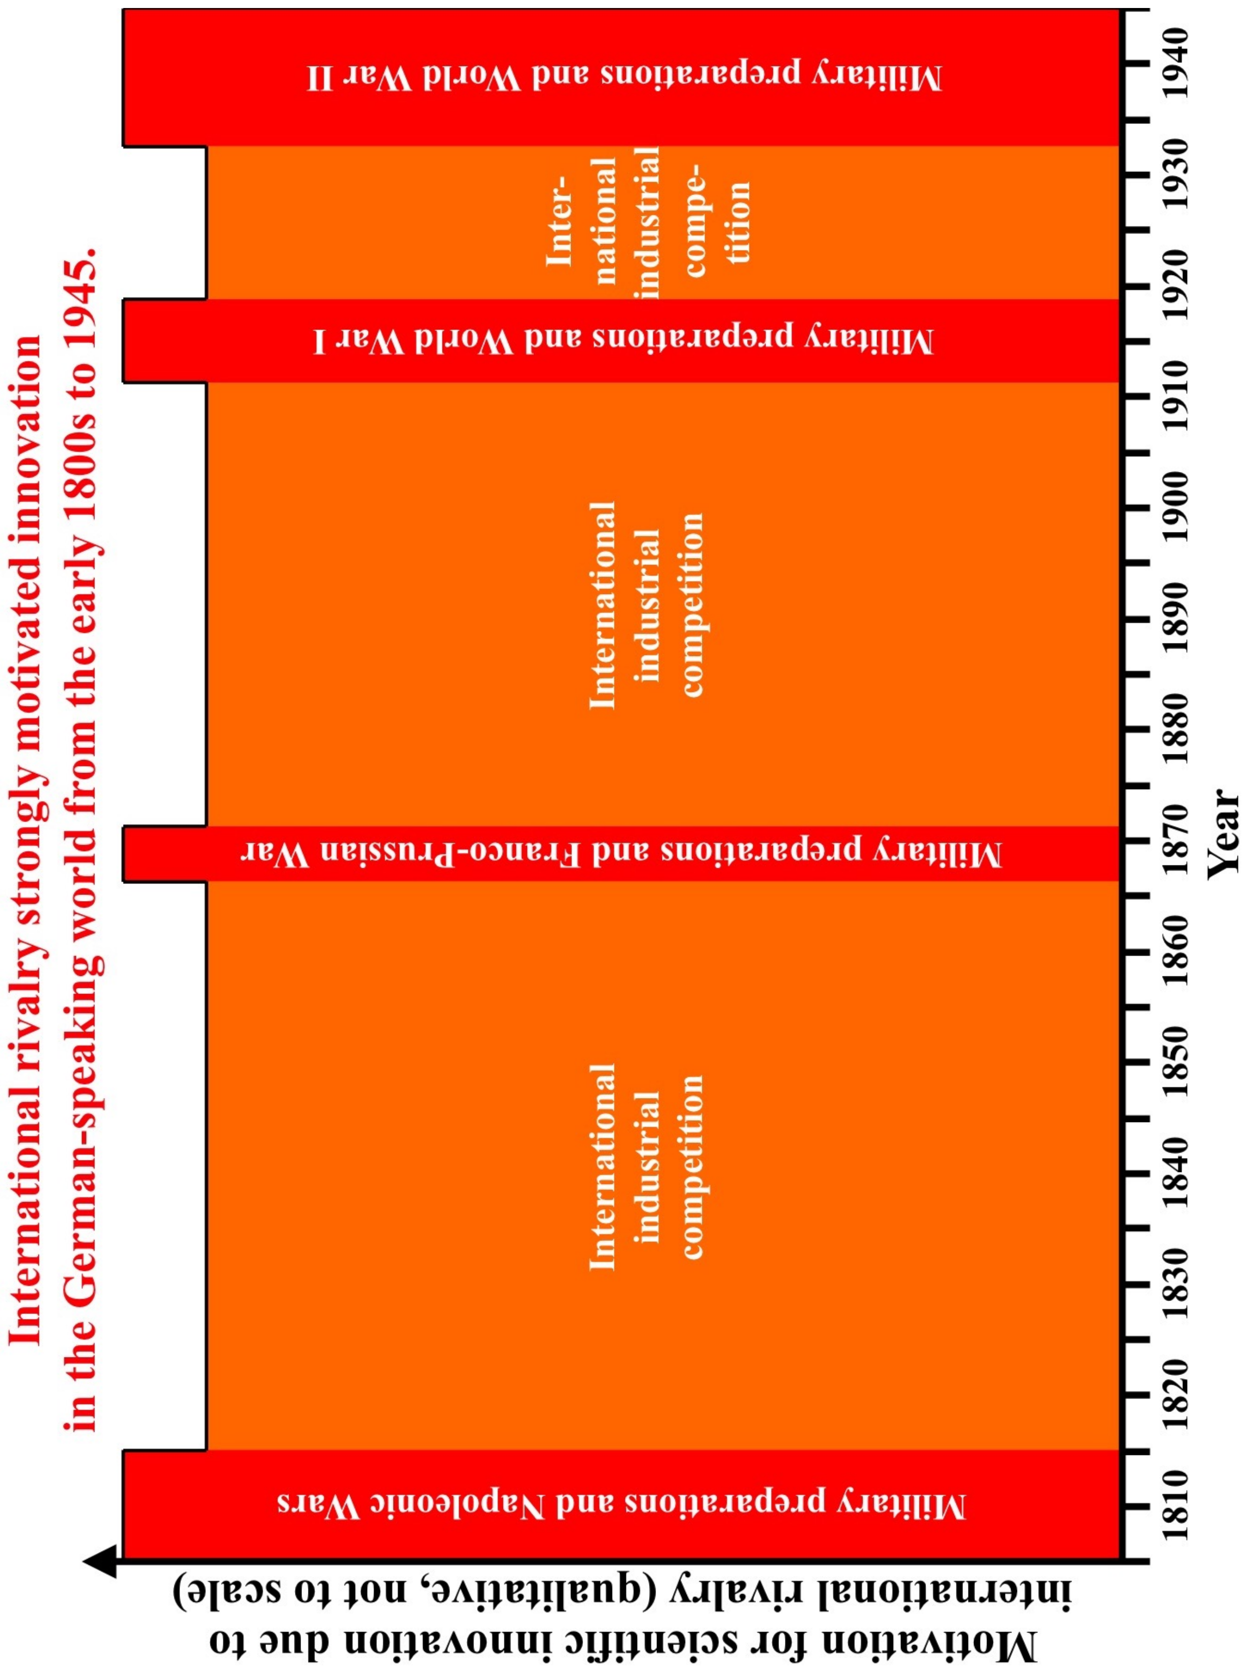


Figure 10.15: International rivalry strongly motivated innovation in the German-speaking world from the early 1800s to 1945.

10.2.10 Industrial Unity of Purpose

Nowadays companies are afraid to create any innovations that they cannot immediately capitalize on themselves, lest any research that they have funded end up benefiting other companies more than their own. In contrast, throughout the late nineteenth and early twentieth centuries, German industry was willing to invest very large sums of money in revolutionary R&D projects. The companies were much more afraid of the possibility that Germany might lose to foreign companies and nations than they were of the possibility that their own company-funded innovations might benefit another German company. Leaders of different German companies were united by a strong sense of common purpose (Fig. 10.16). Ultimately this strong nationalism moved them toward the extreme of massive monopolies like I.G. Farben and the fascist ideology intertwining government and industry.

Ulrich Wengenroth, a scientific historian at the Deutsches Museum in Munich, summarized the history of this German tendency toward "cooperative capitalism" [Landes 2010, pp. 279–280]:

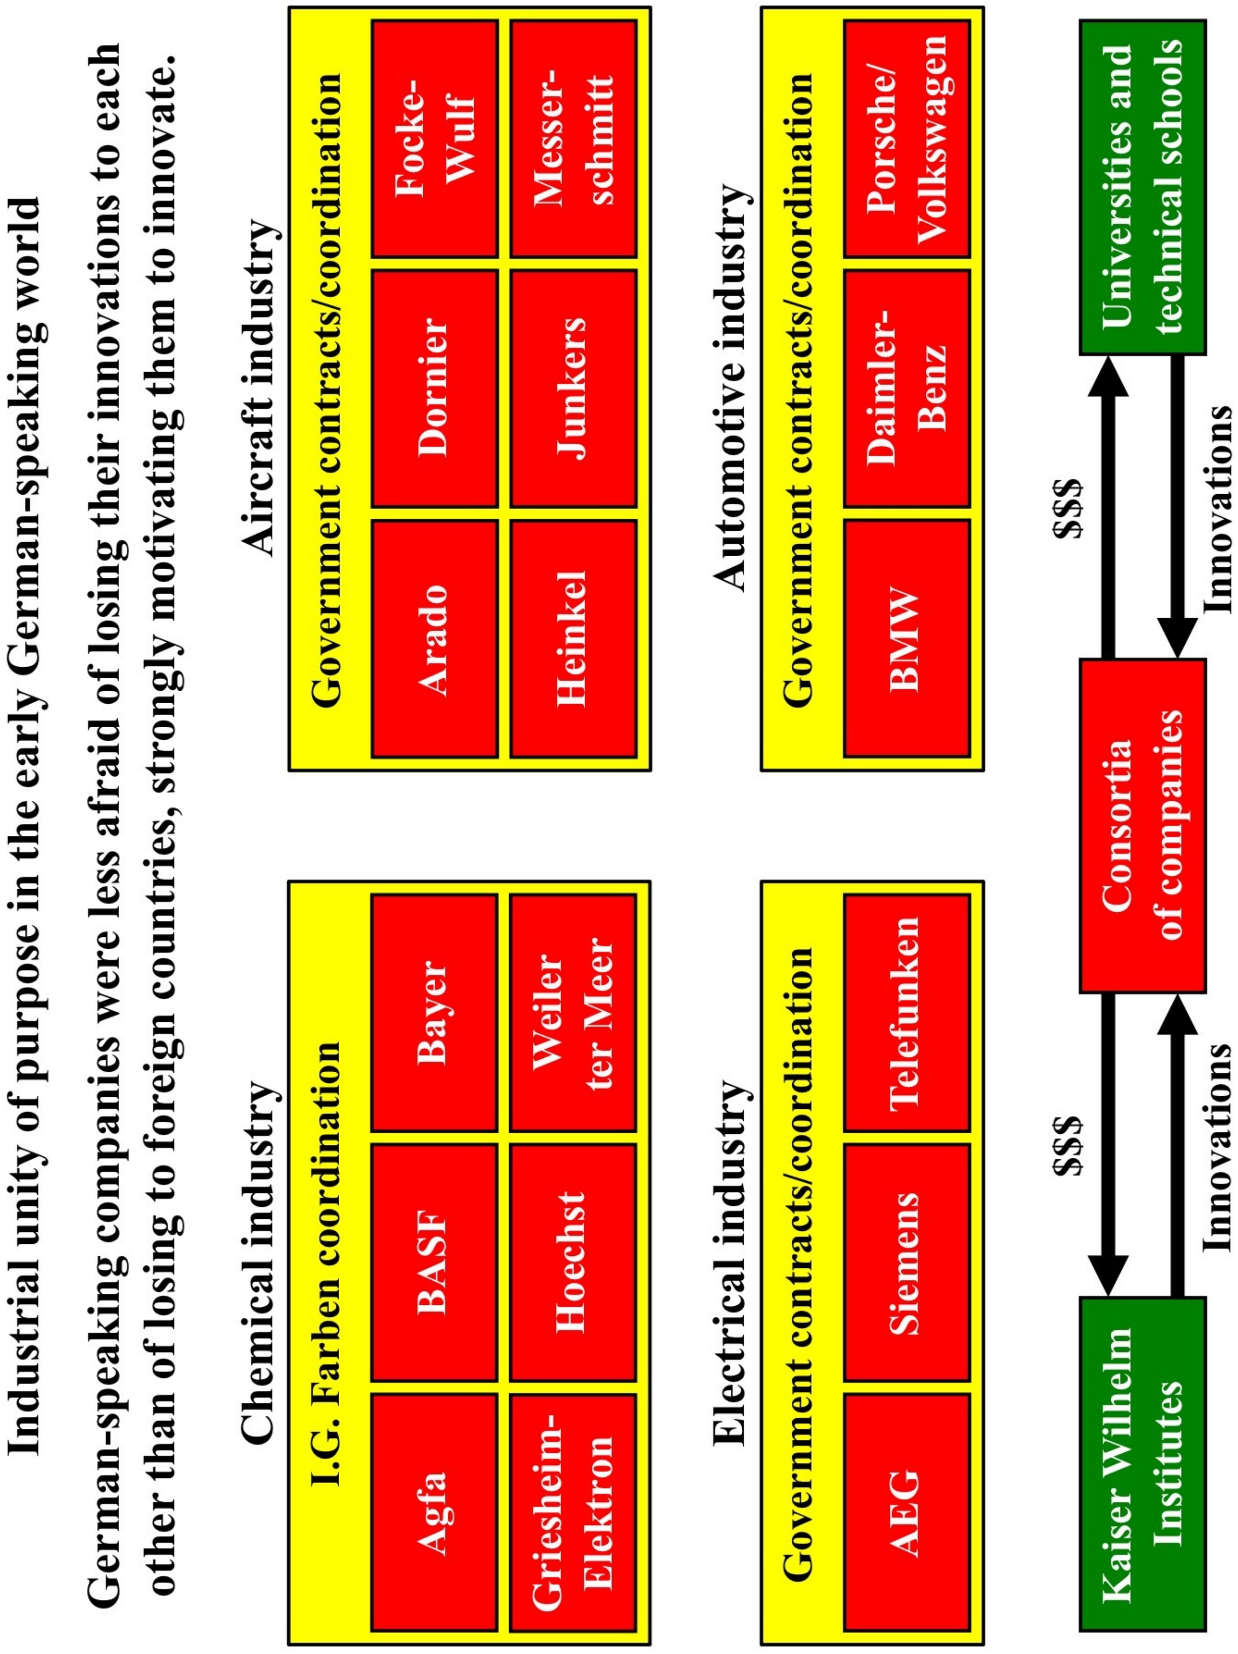
> Cartels mushroomed after the protectionist reversal of the 1870s. They were defended as freedom of contract, and the highest court of the empire in 1897 decided that cartel arrangements were not only legal but binding on all partners and could be enforced. To Alfred Chandler, Jr., this was a watershed setting Germany firmly on the path of cooperative rather than competitive capitalism. By 1897, however, big industry in Germany had already twenty years of intensive cartelization behind it. The climax of cartelization came with the Nazis and their *Zwangskartellgesetz* of 1933, which made cartels mandatory in the interest of Nazi economic planning. After World War II, under pressure from the United States, the cartelization of German industry was largely made illegal if not completely abolished. [...]
>
> Intellectual property rights were hardly protected before 1877 when the German patent law was passed. Before that year, governments of German states, and particularly of Prussia, were reluctant to grant patent protection in an effort to ease transfer of knowledge from abroad. [...] All this changed when Prussia believed that German industry had successfully caught up and was in a position to turn from imitator to bona-fide innovator. The German patent law protected the process rather than the product, thus stimulating research for alternative ways to turn out the same product. This proved to have a highly stimulating effect on corporate research and development.

Wengenroth also gave several examples of how the German propensity for cooperative capitalism greatly benefited the innovation and international competitiveness of German industry in the fields of chemicals, electrical equipment, and machinery [Landes 2010, pp. 290–293]:

> Charts of tar-based products show a wide spectrum from explosives to anesthesia, Bakelite, and a number of synthetic dyestuffs and their intermediates. In protecting processes rather than products the German patent law further stimulated the research drive into ever more fields. It took the German chemical industry's competitors decades and the scrapping of all property rights in the wake of the wars slowly to erode the position it had built by the turn of the century. Only with two paradigm shifts in the industry, from coal to oil and from chemical synthesis to biotechnology, did foreign—mostly

> American—companies draw even with and eventually surpass the “big three,” only two of which are still German with BASF being number one globally, while Hoechst has become part of the French Aventis.
>
> —
>
> An industry that was almost as successful in making the most of the great pool of talent at the many polytechnics was electrical engineering. This industry was governed by two very different titans of German enterprise, Werner Siemens, who had introduced the telegraph to Germany, and Emil Rathenau, the founder of AEG (Allgemeine Electrizitätgesellschaft = General Electric Company). [...]
>
> The outcome on the German market was a duopoly of AEG and Siemens and remained that until the decline of AEG in the 1980s. [...] Although it has been debated whether electrical manufacturing was a science-based industry or an industry-based science in Germany, there is agreement that the close and extensive cooperation of manufacturers and polytechnics greatly helped to solve innumerable problems occurring on the way to innovations that eventually created the high reputation for equipment “made in Germany.”
>
> —
>
> Ludwig Loewe [...] let one of his directors, the twenty-five-year-old Walter Schlesinger, go to the Berlin polytechnic to conduct research in metal cutting using heavy grinding machines. [...] The result was the first ever German dissertation in mechanical engineering, the establishment of a “norm factory” on the premises of Loewe, and the beginning of what was to become the greatest export success of German mechanical industry ever, the DIN (Deutsche Industrie Normen)—German industrial norms used by countries around the world, among them more recently the People’s Republic of China. In creating norms for fits, Schlesinger and his comrades-in-arms—literally, because most breakthroughs happened through World War I—established national norms rather than proprietary factory norms. With national norms, all German industry could participate in decentralized mass production. Products and components designed meeting these norms would always fit together. The test run was arms production in World War I, when a highly decentralized German industry had to turn out components for uniform mass products. [...]
>
> And as Germany moved ahead in creating a system of norms, other countries did not bother to invent something new but adopted DIN norms and later also their electrical counterparts, VDE norms (VDE = German Association of Electrical Manufacturers). There were very few innovations, if any, that helped German industry better to conquer export markets for mechanical and electrical products. Schlesinger and Loewe together had established this path, and others were quick to follow, seeing that agreeing on a common norm helped German business more than going proprietary. It is no surprise that German industry’s tradition of collective action and cooperation was further strengthened by that strategy.

As discussed in Section 11.2.10, many companies in the United States experienced (and greatly benefitted from) a similar unity of purpose during World War II, the Cold War, and the space race, but unfortunately that no longer seems to be true today.



Industrial unity of purpose in the early German-speaking world
German-speaking companies were less afraid of losing their innovations to each other than of losing to foreign countries, strongly motivating them to innovate.

10.2.11 Other Factors

Among the creators from the German-speaking world, there was a disproportionate percentage of scientists and engineers who were Jewish or who at least had some sort of Jewish family background [Ash and Söllner 1996; Fraser 2012; Gerstl 2014; István Hargittai 2006; Lebrecht 2019; Leff 2019; Medawar and Pyke 2000; Nachmansohn 1979].

Country	**Number of Jews**	**% of local population**
Austria	191,000	2.8%
Germany	525,000	0.75%
Czechoslovakia	357,000	2.4%
Hungary	445,000	5.1%
Netherlands	156,000	1.8%
Poland	3,000,000	9.5%
Switzerland	18,000	0.4%
German-speaking world total	4,700,000	3.2%
Albania	200	0.02%
Belgium	60,000	0.7%
Bulgaria	48,500	0.8%
Denmark	5,700	0.15%
Estonia	4,560	0.4%
Finland	1,800	0.05%
France	250,000	0.6%
Greece	73,000	1.2%
Italy	48,000	0.11%
Latvia	95,600	4.9%
Lithuania	155,000	7.6%
Norway	1,400	0.05%
Portugal	1,200	0.02%

United States	4,300,000	3.4%
Other countries	1,500,000	0.1%
Worldwide total	15,300,000	0.73%

Table 10.11: Jewish population in selected countries in 1933.

Table 10.11 shows the Jewish population in various countries in 1933 [https://www.jewishvirtuallibrary.org; https://encyclopedia.ushmm.org/content/en/article/jewish-population-of-europe-in-1933-population-data-by-country]. People of Jewish background made up only 0.75% of the population of Germany, 3.2% of the population of the greater German-speaking world, 1.7% of the total European population, and 0.73% of the total world population.

Despite being such a small percentage of the total population, people of Jewish background composed 15–33% of the German scientific research system, according to various estimates [Ash and Söllner 1996, p. 7].

Prior to the Third Reich (before 1933), 17% (17 out of 99) of scientific Nobel Prize winners were of Jewish background, as shown in Table 10.12. As of 2013, 25% of scientific Nobel Prize winners were of Jewish background (144 of the 566 winners for 1901–2013 [Gerstl 2014, pp. 82–96]); many of those were from the German-speaking world, were immigrants from the German-speaking world, or were the children of immigrants from the German-speaking world.

By these metrics, people of Jewish family background were ∼10–30 times more likely to be scientific creators than one would expect from overall demographic figures alone.

Table 10.12: Jewish Nobel Laureates in science prior to the Third Reich (1901–1932).

In his analysis of why such a disproportionately large percentage of Nobel-Prize-winning scientists have been Jewish, Ronald Gerstl proposed that a number of factors were responsible [Gerstl 2014, pp. 70–74]:

> The Jewish family has traditionally been a secure and nurturing unit. The incidences of family violence, abandonment, failure to provide support for wife and children, alcoholism, unwed mothers and other social ills are relatively rare. [...]
>
> Overall, Jewish families in modern times have considerably fewer children than the average birthrate. Consequently Jewish parents have been able to dedicate more time and money to each child's welfare, education and cultural development. [...]
>
> The Jews have a long history of dedication to learning going back to ancient times. Judaism required every Jewish man to study the Torah and the Talmud, which necessitated literacy. [...]
>
> Whereas most other parents in poor or modest circumstances were anxious for their offspring to join the workforce, Jewish parents, including the poor, were willing to make sacrifices so that their children could remain in school as long as possible. [...]
>
> Children of immigrant parents felt the need to succeed to recompense parents for their sacrifices. Beyond the first generation, parents continued to instill high expectations in their offspring. [...]
>
> Centuries of persecution may actually have strengthened Jews' resolve and tenacity. Jews felt like outsiders in many countries in which they dwelled, which may have given them an incentive to prove their worth rather than complacently accept their lot. Often differing from the general culture, Jews have been less likely to cling to conventional wisdom and preconceptions. This allowed them to be more open to change, to adapt more quickly to new circumstances and to perceive new opportunities. [...]
>
> That said, cultural factors and values alone cannot fully explain the extent of Jewish achievements. Some genetic predisposition has to be considered as well, realizing that both are inextricably linked.

Whereas Ronald Gerstl only listed genetic factors as one possible cause among many others, Charles Murray focused on the genetic theory in several publications [Herrnstein and Murray 1996; Murray 2007, 2020]. Other scholars have also argued for and against the genetic theory [e.g., Cochran et al. 2006; Ferguson 2007; Pinker 2006].

Historian of science Noah Efron criticized both the theories about Jewish educational background and those about Jewish genetics, and proposed that Jewish prominence in science was only a transient historical phenomenon caused by the career opportunities that were and were not open to students of Jewish background in certain countries in the late nineteenth and early twentieth centuries [Efron 2006, 2013, 2014]. Efron summarized his arguments [Efron 2013]:

> Elsewhere, rabbis and pundits tried to puzzle out what it is about Jews that make them so super at science.

> Broadly, two sorts of theories have been floated. One is that Jews have primo genes. Charles Murray, the Enterprise Institute scholar and co-author of *The Bell Curve*, set out the case for this a few years ago in an essay in *Commentary* called "Jewish Genius," writing bluntly that "something in the genes explains elevated Jewish IQ." Another theory is that Jews love hitting the books, as Israeli economics laureate Robert Aumann told the army radio station Galei Tzahal: Jewish homes have overflowing bookshelves. Throughout the generations we have given great honor to this intellectual pursuit.
>
> There are good reasons to doubt both sorts of theories. For one thing, Jewish excellence in science is a new thing. When the great Jewish folklorist Joseph Jacobs set out in 1886 to compare the talents of Jews with the talents of other Westerners, he found their performance mediocre in every science save medicine. In the first decades of the 20th century, Princeton psychologist Carl Brigham tested the intelligence of Jews in America, and concluded they "had an average intelligence below those from all other countries except Poland and Italy." Jewish excellence in science is a phenomenon that flowered in the decades before and, especially, after the Second World War; it is too recent a phenomenon to be explained by natural selection, or even by putative ancient cultural traditions.
>
> The real explanation of Jewish success in science lies elsewhere. The 20th century began with massive migrations of Jews, to the United States, to the cities of Russia (and then the Soviet Union), and to Palestine. In each of these new lands, Jews turned to science in great numbers because it promised a way to transcend the old world orders that had for so long excluded most Jews from power, wealth and society. Science, based as it is on values of universality, impartiality and meritocracy, appealed powerfully for Jews seeking to succeed in their new homes. It is not so much what Jews were (smart, bookish) that explains their success in science, as what we wanted to be (equal, accepted, esteemed), and in what sorts of places we wanted to live (liberal and meritocratic societies). [...]
>
> What bugs me about attributing the remarkable prominence of Jews among Nobel laureates to genes or enduring cultural traditions is that doing so suggests that Jewish success in science will inevitably continue as a matter of course. Most likely it won't. The percentages of Jews among new American Ph.D.s in the sciences has declined greatly over the past generation. In Israel, spending on higher education has continued to decline during most of the same period; to many of the growing numbers in Israel who embrace religion, the appeal of science has nearly vanished. The passions that drew Jews to sciences in such great numbers have dissipated.

Whatever the explanation for the large numbers of Jewish creators, family background appears to help but is not sufficient by itself. For example, the modern United States has roughly six million people of Jewish background [Gerstl 2014, pp. 37–38], and millions of people from each of many other family backgrounds. If any one or more of those family backgrounds were automatically the key to producing revolutionary scientific creators, the modern United States would have produced far more revolutionary innovators and innovations than it appears to have. Although the United States has vast numbers of scientists and engineers, very few of those appear to be producing the sorts of truly revolutionary creations that were much more common in the earlier German-speaking world. Thus the most critical factors appear to be systemic approaches, such as those considered in previous sections, that cultivate, support, and reward revolutionary creators and creations.

In addition to the factors already considered in this chapter, it is possible that other factors helped or hindered scientific innovation in the former German-speaking world. In the future, scholars who examine this problem further should evaluate factors such as (but not limited to) the following for the older German-speaking world, the U.S. research system, and other innovation systems, and determine how much if any effect each factor has had on innovation:

- Being an immigrant, or the descendant of people who recently immigrated to that country or region [Hathaway 2017].
  - For immigrants or the children of immigrants who initially have little wealth or status in their new country, a scientific education and career may be one of the few available paths offering the greatest opportunity for elevation in society. In theory (although not always in practice), someone could go from disregarded poverty to social elite by learning enough and working hard enough. Due to discrimination, upfront financial costs, or other societal barriers or prerequisites, there may be few other career paths that are open and that have so much potential. (This was essentially Noah Efron's explanation for the success of Jewish scientists [Efron 2013], but it could apply to scientists coming from other family backgrounds as well.)
  - Perhaps immigrants are a self-selected group with more independent initiative, greater creativity, and more willingness to work hard in order to leave one country and settle in another.
  - Maybe immigrants, or the children of immigrants, feel that they have more to prove or further to rise in their new country, and therefore on average dream bigger and work harder than those whose families have lived in that country for many generations.
  - Perhaps immigrant families, feeling more alone in a foreign country, are more closely knit and more supportive, which could promote more positive personality characteristics and greater success in life.
- Other family backgrounds that are disproportionately frequent or infrequent among innovators (number of siblings, birth order, parental education and careers, religion and religiosity, wealth, geographical location, etc.).
- The ease with which students could transfer among courses, majors, and schools within the educational system.
- The average total cost required to obtain a doctoral (or other final) degree.
- The annual ratio of the number of available good jobs to the number of students graduating with a final science or engineering degree.
- The average age at which children who ultimately became scientists or engineers first decided that they wanted to pursue that educational and career path.
- The average age at which scientists or engineers first obtained a job that gave them the freedom and resources to pursue their own ideas.

- The average age at which scientists or engineers came up with their first major innovation.
- The average age at which scientists or engineers came up with their last major innovation.
- The average number of innovations per year per person in the innovation system. (Exactly how would an innovation be defined?)
- The average number of publications per year per person in the innovation system (although greater quantity does not necessarily mean greater quality, and might in fact be achieved at the expense of quality).
- The average number of patents per year per person in the innovation system (again, quantity may not be indicative of quality).
- The average number of technology startup companies or laboratories per year per person in the innovation system (although widespread, formal startup companies may be a more modern concept, and it may be difficult to find analogous data for older innovation systems).
- The average amount of total research funding per year per person in the innovation system.
- The average salaries for various categories of science, engineering, and medical professionals.
- The average salaries for teachers at different levels and in different fields.
- The average duration of a research project (from conception to viable demonstration).
- The average duration of a research job.
- The average duration of a research career.
- The average number of hours per year that a person in the system spent on research (actual research, not paperwork related to research).
- The average number of hours per year that a person spent on teaching (actual teaching, not paperwork related to teaching).
- The average number of hours per year that a person spent on scientifically directly productive work other than research and teaching (such as reading).
- The average number of hours per year that a person spent on sponsor proposals and reporting requirements. (Even though many would deem these necessary, they can siphon enormous amounts of time and energy away from actual research.)
- The average number of hours per year that a person spent preparing and submitting journal articles, books, etc. for publication. (Although publications are an essential part of a healthy scientific system, when publications are emphasized to an extreme, they can also divert vast amounts of time and energy away from actual research.)

- The average number of hours per year that a person spent on other work that is less directly productive scientifically, such as required meetings, personnel training, human-resources-related tasks, contract administration, ordering, inventory, approvals, evaluations, other paperwork, etc.

- The ease with which researchers could access all the relevant scientific literature (due to financial, physical, or online restrictions).

- The ease with which researchers could access relevant facilities for laboratory experiments or engineering construction.

- The ease with which researchers could exchange ideas with other relevant researchers in technical conferences, seminars, formal organizations, informal or after-hours organizations, etc.

- The average number of technical supporting personnel (e.g., research assistants) per researcher.

- The average number of nontechnical supporting personnel (e.g., clerical and logistics assistants) per researcher.

- How assistants, researchers, managers, and sponsors were evaluated, selected, and promoted (based on good work and talent vs. politics and favoritism, etc.).

- How major decisions on research programs were made by individuals, organizations, and sponsors (short-term vs. long-term gain, logical reasoning vs. hype and hope, etc.).

- The average sizes and compositions of research groups in different fields and research sectors (academic, corporate, and government laboratories).

- The average probability that a research proposal will be funded.

- The fractions of funding awarded by peer review or other processes, and how those processes work.

- The fraction of research projects that led to a viable demonstration. (Even though it may be bad if the fraction is too low, if the fraction is too high, that could indicate that higher-risk, more innovative projects are being avoided instead of pursued.)

- The fraction of viable demonstrations that ultimately led to a final product.

- How innovative research projects were on average, on a scale from evolutionary (straightforward extensions of what is already known) to revolutionary. (Are there objective, quantifiable, reproducible ways in which the innovativeness of projects can be evaluated?)

Ideally, data such as that described above should be plotted versus time to see how things changed over many decades within a given innovation system, as well as how things appear to be similar or different for different innovation systems.

Chapter 11

Immortalizing the Creations and Forgetting the Creators

Was man nicht aufgibt, hat man nie verloren. What is not abandoned is never completely lost.

Friedrich Schiller. 1800. *Maria Stuart*, Act II, Scene 5.

As discussed in Chapter 10, the German-speaking research world had several systemic practices that allowed it to produce a huge number of revolutionary scientific creators and creations. As covered in this chapter, the global research system eagerly adopted the creations of the earlier German-speaking world, yet ultimately largely forgot both the creators and the systemic approaches that had made those creations possible.

Section 11.1 outlines the many ways in which creations and creators were transferred to the global research system, especially the United States, before, during, and after the Third Reich.

Section 11.2 analyzes the general innovation-promoting approaches that the U.S. research system borrowed from the earlier German-speaking world and used with relative success during the 1940s–1960s.

Section 11.3 examines how the modern innovation system began a long, slow decline starting in the 1970s. By that time, most of the German-speaking creators had retired or died, their creations had been refined to the point of diminishing incremental returns, and the research system had abandoned most of the German-like practices it had adopted, greatly reducing its efficiency at producing entirely new revolutionary innovators and innovations.

11.1 Creations and Creators Transferred from the German-Speaking World

Before, during, and after the Third Reich, virtually all of the creations, most of the creators, and a number of the underlying general practices were transferred from the German-speaking world to the global research system, especially the early U.S. research system. The United States and the rest of the global research system spent many decades copying, optimizing, and mass-producing the innovations that had been created by the earlier German-speaking world, resulting in our modern world of jet aircraft, electronics, and pharmaceuticals. Most of the creators who had already died or who remained in German-speaking areas were forgotten by the non-German-speaking world, which often mistakenly attributed their creations to whichever non-German-speaking individuals or organizations had acquired their technical information. Most of the creators who emigrated out of German-speaking areas led well-funded but very quiet lives perfecting their creations and were also ultimately forgotten; only a few, such as Albert Einstein, Edward Teller, and Wernher von Braun, sought or received lasting fame.

11.1.1 Before the Third Reich

Even well before the Third Reich, the German-speaking world had significant influences on the development of research systems in the United States and elsewhere. In particular, some German-speaking scientists left their own world in search of opportunities elsewhere, a number of U.S. scientists were educated in the German-speaking world, universities in the United States and other countries were consciously designed or redesigned to mimic the successful model of universities in the German-speaking world, and many technological patents and factories were forcibly transferred during and after World War I.

Émigrés before the Third Reich

Long before the Third Reich came to power and triggered a mass exodus, a steady stream of German-speaking émigrés moved to the United States (or other countries) to seek new business opportunities. Just a few of the better-known examples of German-speaking creators who moved to the United States before the Third Reich are listed in Table 11.1.

U.S. scientists and engineers educated in the German-speaking world

In addition to German-speaking creators who moved to the United States, there were a large number of Americans who travelled to the German-speaking world for education and training and then returned to the United States. Over 9000 Americans attended German universities (especially Berlin, Göttingen, Halle, and Heidelberg) between 1820 and 1920 [Röhrs 1995, p. 11]. Including Americans who attended before that time or up to the Third Reich, as well as those who went to German-speaking universities in countries other than Germany, probably well over 10,000 Americans studied in the German-speaking world (in science, math, engineering, and other areas) and brought what they had learned back to the United States.

A few examples of prominent U.S.-born scientists and scholars who received at least part of their education in the German-speaking world are listed in Table 11.2.

Name	**Nationality**	**Scientific contributions**
Louis Agassiz	Swiss	Paleontology
Walter Baade	German	Astronomy
John Jacob Bausch Henry Lomb Ernst Grundlach	German German German	Bausch & Lomb lenses, eyeglasses, microscopes, telescopes, etc.
Emil(e) Berliner	German	Microphone, record player, helicopter
Herman Frasch	German	Oil refining, sulfur
Beno Gutenberg	German	Seismology, earthquake magnitudes, etc.
Karl Herzfeld	Austrian	Quantum and statistical physics
Hermann Lemp	Swiss	Diesel-electric locomotives
Julius Edgar Lilienfeld	Austrian	Field effect transistor

Name	**German education**	**Scientific contributions**
James M. Crafts	Studied with Robert Bunsen	Organic chemistry
William Duane	Ph.D. (Berlin, 1897) under Max Planck	X-rays and radioactive elements
Josiah Gibbs	Studied math and physics under Gustav Kirchhoff and Hermann von Helmholtz	Statistical and thermal physics
Percy Lavon Julian	Ph.D. (Vienna, 1931) with Ernst Späth	Organic chemistry
Irving Langmuir	Ph.D. (Göttingen, 1906) under Walther Nernst	Physical chemistry, General Electric R&D
Arthur Michael	Research assistant for Hofmann, Bunsen	Organic chemistry
J. Robert Oppenheimer	Ph.D. (Göttingen, 1927) under Max Born	Nuclear physics, Manhattan Project
Linus Pauling	Studied quantum theory under Arnold Sommerfeld, Erwin Schrödinger	Chemistry
Ira Remsen	Ph.D. (Göttingen, 1870) with Wilhelm Fittig	Organic chemistry
Howard Robertson	Studied physics under Hermann Weyl, Max Born, and Arnold Sommerfeld	Applied mathematics, cosmology
Edmund Beecher Wilson	Studied developmental biology under Rudolf Leuckart, Carl Ludwig, Theodor Boveri	Developmental biology

Table 11.2: Examples of U.S.-born scientists and scholars who received at least part of their education in the German-speaking world.

Influence on the structure of the U.S. research system before the Third Reich

Up through the nineteenth century, university education in the United States was largely rote learning, with little freedom to choose among courses or to conduct research. Many of the Americans who had been educated in the German-speaking world and returned home wanted to instill U.S. universities with much more freedom, originality, and academic research like what they had witnessed in Europe. This motivation led to the founding of universities such as:

- Massachusetts Institute of Technology in 1861 in Boston (it moved to Cambridge in 1916) [Stratton and Mannix 2005].
- Johns Hopkins University in 1876 in Baltimore, Maryland [Thelin 2019].
- Stanford University in 1891 in Stanford, California [Wels 1999].
- California Institute of Technology in 1891 in Pasadena [Goodstein 1991].

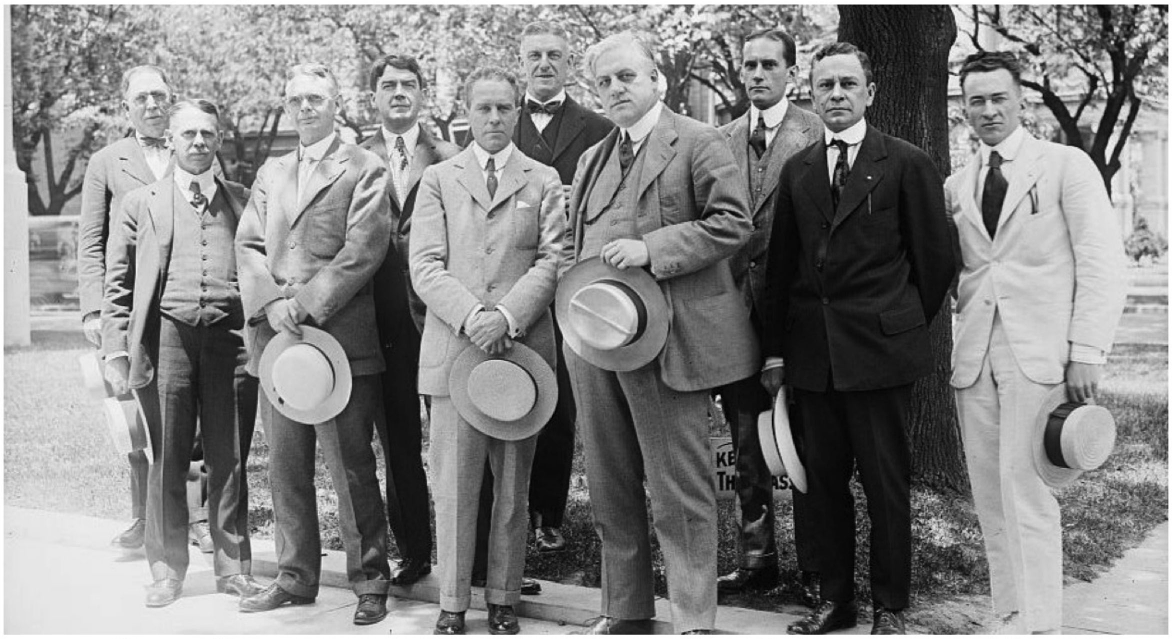
These new schools were intentionally designed to emulate German universities by having faculty and students participate in both courses and original research. Following the success of such schools, older U.S. universities gradually reformed, and by the post-World-War-II era, most major U.S. universities were generally following the same German model [Ben-David 1992; Röhrs 1995; Schwinges 2007; Tanaka 2005].

Just as U.S. universities were deliberately transformed to be more German-like, U.S. companies were also transformed to be more like science- and engineering-based companies in the German-speaking world, by forcibly seizing technological patents and even entire factories from the German-speaking world, as discussed below.

Transferred companies, patents, and other resources

The U.S. Trading with the Enemy Act of 1917 resulted in the large-scale appropriation of resources from German speakers (both those living in Europe and those living in the United States) to the United States government and to certain non-German-speaking U.S. citizens and companies that were politically well connected [Coben 1963; Gross 2014, 2015]. By invoking this and other laws during and after World War I, the U.S. Office of Alien Property Custodian put thousands of German-speaking U.S. residents (both recent immigrants and longtime U.S. residents who had come from Germany, Austro-Hungary, and even Switzerland, which was not a party to World War I) in concentration camps and held them in the camps until 1920, long after the war (Fig. 11.1). From those and countless other German-speaking individuals in the United States and overseas, the Office of the Alien Property Custodian seized over $500 million dollars (as valued then, which would be far more in modern dollars) worth of patents, property, businesses, and possessions. Those permanent seizures included large numbers of patented inventions and processes, as well as the U.S. branches of German and Austro-Hungarian scientific and engineering companies such as Bayer and Merck (p. 2217).

Senior staff of the U.S. Alien Property Custodian's office (1918), which seized over $500 million dollars (as valued then) worth of patents, property, businesses, and possessions from German speakers living in Europe and in the United States



One of the concentration camps for German-speaking residents of the United States during World War I

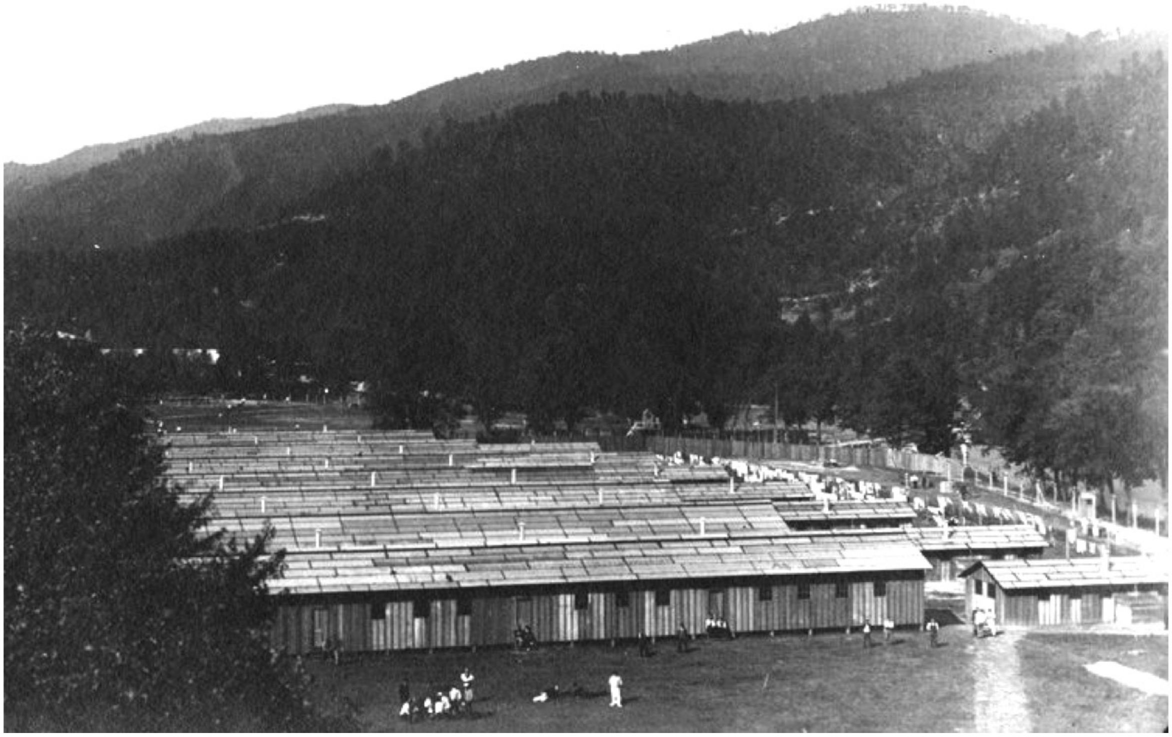


Figure 11.1: During and after World War I, the U.S. Office of the Alien Property Custodian (run by A. Mitchell Palmer, foremost in the upper photograph) put thousands of German-speaking residents of the United States in concentration camps and seized over $500 million dollars (as valued then) worth of patents, property, businesses, and possessions from German speakers living in Europe and in the United States.

The details and impact of these World War I seizures warrant a detailed study, yet unfortunately there does not appear to be a comprehensive modern account. However, the journalist Daniel Gross wrote two articles that gave insights into this history. Gross described the concentration camps and property seizures [Gross 2014]:

> Posselt was a young editor and translator who emigrated from Austria-Hungary in 1914. His nationality—like that of millions of German-speaking immigrants in the United States during World War I—attracted suspicion and anger from nationalistic Americans. In the course of the war, the federal government registered around half a million "enemy alien" civilians, spied on many of them, and sent approximately 6,000 men and a few women to internment camps. Perhaps more strikingly, it seized huge troves of private property with dubious relevance to the war effort, ultimately amassing assets worth more than half a billion dollars—close to the entire federal budget of pre-war America. [...]
>
> [A]t Fort Oglethorpe, Posselt described an odd collection of imprisoned intellectuals. They were allowed to organize courses taught by interned professors of biology, mathematics, literature, and languages. Several dozen musicians, many of whom had been recruited from Europe to join American orchestras, regularly performed to help keep up morale. [...]
>
> In retrospect, American internment policies are troubling, but they're dwarfed by a quieter and more sweeping practice of property seizure. Under the Trading with the Enemy Act, President Wilson appointed an "Alien Property Custodian" named A. Mitchell Palmer to take control of property that might hinder the war effort. Among other things, this meant all property belonging to interned immigrants, regardless of the charges (or lack thereof). "All aliens interned by the government are regarded as enemies," wrote Palmer, "and their property is treated accordingly."
>
> The basic argument was that property seizure prevented immigrants from financially or materially supporting enemies of America. Under Palmer's direction, the Office of the Alien Property Custodian grew to employ hundreds of officials and used several high-profile cases of espionage and industrial sabotage to defend its work. German chemical companies in the United States were particularly vulnerable to seizure: not only did dye and pharmaceutical companies divert raw materials from the war effort, they could also in theory produce explosives.
>
> The agency's powers were remarkably broad, however. In *Munsey's Magazine*, Palmer described the Alien Property Custodian as "the biggest general store in the country," noting that some of the companies seized were involved in "pencil-making in New Jersey, chocolate manufacture in Connecticut, [and] beer-brewing in Chicago." There were small holdings seized from individuals, too. "Among them," he continued with an odd hint of pride, "are some rugs in New York; three horses near Joplin, Mississippi; [and] a carload of cedar logs in the South." (Historians will probably never figure out why Palmer wanted those rugs in New York.) The historian Adam Hodges found that even women who were American citizens, if married to German and Austro-Hungarian immigrants, were classified as enemy aliens— and they alone lost a combined $25 million in property to the government.

> The war ended in November 1918, just a year after the passage of the Trading with the Enemy Act. In that time, the Alien Property Custodian had acquired hundreds of millions of dollars in private property. In a move that was later widely criticized—and that political allies of the Alien Property Custodian likely profited from directly—Palmer announced that all of the seized property would be "Americanized," or sold to U.S. citizens, partly in the hopes of crippling German industries. (His attitude echoed a wider sentiment that the Central Powers deserved to pay dearly for the vast destruction of the war.) In one high-profile example, the chemical company Bayer was auctioned on the steps of its factory in New York. Bayer lost its U.S. patent for aspirin, one of the most valuable drugs ever produced.
>
> "The same peace which frees the world from the menace of autocratic militarism of the German Empire," Palmer argued, "should free it from the menace of its autocratic industrialism as well." Immigrant property, in his view, was just an extension of German and Austro-Hungarian property—which gave America the right to take it. Several lawsuits later disputed his authority to do so, including one that reached the Supreme Court, but his actions were found to be legal under wartime laws. In fact, the agency's reputation was sufficiently intact that President Franklin Roosevelt re-established it during World War II. [...]
>
> The last prisoner wasn't released until April 1920, a full year and a half after the end of the war. As Glidden described it: "When the camps did close scarcely anyone cared or noticed."

As mentioned by Gross, the Alien Property Custodian during the period 1917–1919 was Alexander Mitchell Palmer (1872–1936, closest to the camera in the upper half of Fig. 11.1). Using the over $500 million of property that his office seized, Palmer acquired power and wealth for himself and his political and business associates. His actions while Alien Property Custodian were so highly regarded by the federal government that he was then elevated to the position of Attorney General of the United States 1919–1921, during which time he led the "Palmer raids" that widely terrorized American communities of immigrants from Europe [Coben 1963].

Daniel Gross added more details about this history in another article [Gross 2015]:

> Ties between German and American chemistry were even tighter in the industrial sphere. Many of the United States' prewar dyestuff and pharmaceutical suppliers were actually branches of German corporations. Americans who wanted a competitive education often traveled to German universities to study chemistry, while German chemists who sought new opportunities came to America. During the war, however, the United States subverted and harnessed the resources of its German competition. [...]
>
> Six months after war was declared, suspicious American authorities gained the legal power to act against German companies. Congress passed the Trading with the Enemy Act, and a man named Mitchell Palmer was appointed Alien Property Custodian. Palmer's office began receiving thousands of reports of enemy-held property. Factories and businesses owned by German nationals were seized by the government, along with thousands of valuable chemical patents. Beckers's former employer, the American branch

> of Bayer, was seized. Many of its employees were even imprisoned at Fort Oglethorpe, Georgia, an internment camp that today has been largely forgotten.
>
> World War I helped erode the advantages of German chemistry. When hostilities in Europe finally ended in 1918, the United States was producing four times as much poison gas as Germany. Palmer, perhaps recognizing that his wartime powers would soon wane, quickly disposed of confiscated holdings worth millions of dollars. Bayer was sold at a public auction on the company steps.

After World War I, the U.S. Office of Alien Property Custodian was viewed as so successful that it was revived and extensively used during and after World War II as well (p. 2108).

In addition to the over half-billion 1918 dollars worth of property seized by the Alien Property Custodian, billions of dollars of reparations (in both property and money) were taken from Germany, Austria, and Hungary after the war. The total reparations paid by Germany amounted to at least 67.7 billion marks or 17 billion 1918-era dollars, equivalent to many years worth of spending by the U.S. federal government at that time. In fact, German reparations obligations for World War I continued even long after World War II, and the final payment from Germany to the United States was not made until 3 October 2010 [https://www.deutschlandfunk.de/das-ende-der-reparationszahlungen-vom-1-weltkrieg.795.de.html?dram:article_id=119010]. Separate reparations of property and money were extracted from Austria and Hungary.

Thus during and after World War I, the German-speaking world transferred to the United States and other countries not only technological patents and factories, but also enough money to fund their continued development and operation for decades.

11.1.2 During the Third Reich

There was a great deal of innovation transfer out of the German-speaking world during the Third Reich, 1933–1945. This transfer took the form of large numbers of émigré scientists and engineers, critical knowledge transferred by them or via other routes, and influence on the wartime structure of the U.S. research system.

Émigrés during the Third Reich

The Third Reich's vicious persecution of people who were of Jewish descent and/or who were perceived as political opponents drove roughly 25% of scientists and engineers to leave the German-speaking world. Over half of those moved to the United States, most of the rest moved to the United Kingdom, and a smaller number went to other countries. This mass exodus was the beginning of the end of the German-speaking scientific world, but a great boon for the countries receiving these talented creators [Ash and Söllner 1996; Fraser 2012; István Hargittai 2006; Leff 2019; Medawar and Pyke 2000; Nachmansohn 1979].

Some examples (though by no means an exhaustive list) of German-speaking creators who moved to the United States during this time are listed in Table 11.3. Note that for thoroughness, this list includes Theodore von Kármán, who came to the United States just before the Third Reich (in 1930) but is generally grouped with the Hungarian refugees from the Third Reich dubbed the "Martians," as well as some younger scientists who completed their education in the United States.

Name	**Nationality**	**Scientific contributions**
Robert Adler	Austrian	Ultrasonic signals
Valentine Bargmann	German	Relativistic physics
Peter Bergmann	German	Relativistic physics
Max Bergmann	German	Proteins
Hans Bethe	German	Solar fusion, Manhattan Project
Erwin Biel	Austrian	Climatology
Marietta Blau	Austrian	Particle detectors
Felix Bloch	Swiss	Solid state physics, NMR, Manhattan Project, radar
Konrad Bloch	German	Cholesterol metabolism/hormones, fatty acid metabolism
Richard Brauer	German	Applied mathematics
Richard Courant	German	Applied mathematics
Max Dehn	German	Applied mathematics
Peter Debye	Dutch	Solid state physics, quantum theory, electrolytes
Max Delbrück	German	Gene structure and mutation, phage genetics
Albert Einstein	German	Relativity, statistical physics, quantum physics
Walter Elsasser	German	Earth's magnetic field
Paul Erdös	Hungarian	Applied mathematics
Kasimir Fajans	Polish	Radioactive elements, inorganic chemistry
James Franck	German	Atomic energy levels, photosynthesis, Manhattan Project
George Gamow	Russian	Nuclear physics

Lise Meitner	Austrian	Sweden	Nuclear fission
Karl Przibram	Austrian	Belgium	Nuclear physics
Richard Willstätter	German	Switzerland	Chlorophyll, chromatography, gas mask filters, enzymes

Table 11.5: Examples of German-speaking creators who emigrated to other countries during the Third Reich.

Kurt Mendelssohn, a German scientist who moved to the United Kingdom, described the whole wave of German-speaking creators who emigrated during the Third Reich, as well as their enormous impact on the countries that received them [Mendelssohn 1973, pp. 175–176]:

> Oxford may have been the first place where German refugee scientists found an opportunity to continue their work; it did not remain the only one. The new Diaspora covered the world. From England to Australia, from America to India, there was hardly a university which did not give shelter and a place of work to the displaced scholars. They, in turn, did all they could by teaching and research to repay the hospitality they were receiving. Around groups of them, or even individuals, there sprang up new schools, recruited from the local students who, in turn, carried forward the heritage of all that had been good and useful in German academic life. Far from destroying the spirit of German scholarship, the Nazis had spread it all over the world. Only Germany was to be the loser.

Scientific knowledge transferred during the Third Reich

A large amount of scientific knowledge was transferred out of the German-speaking world during this time via several routes:

- Émigré scientists and engineers.
- Captured and interrogated scientists, engineers, and military personnel [for example those interrogated at Fort Hunt, Virginia (pp. 2045, 4883) and Wright Field, Ohio (p. 2046)].
- Published scientific literature and patents.

This transferred scientific knowledge was employed by well-funded wartime programs in the United States and United Kingdom.

P.O. BOX 1142

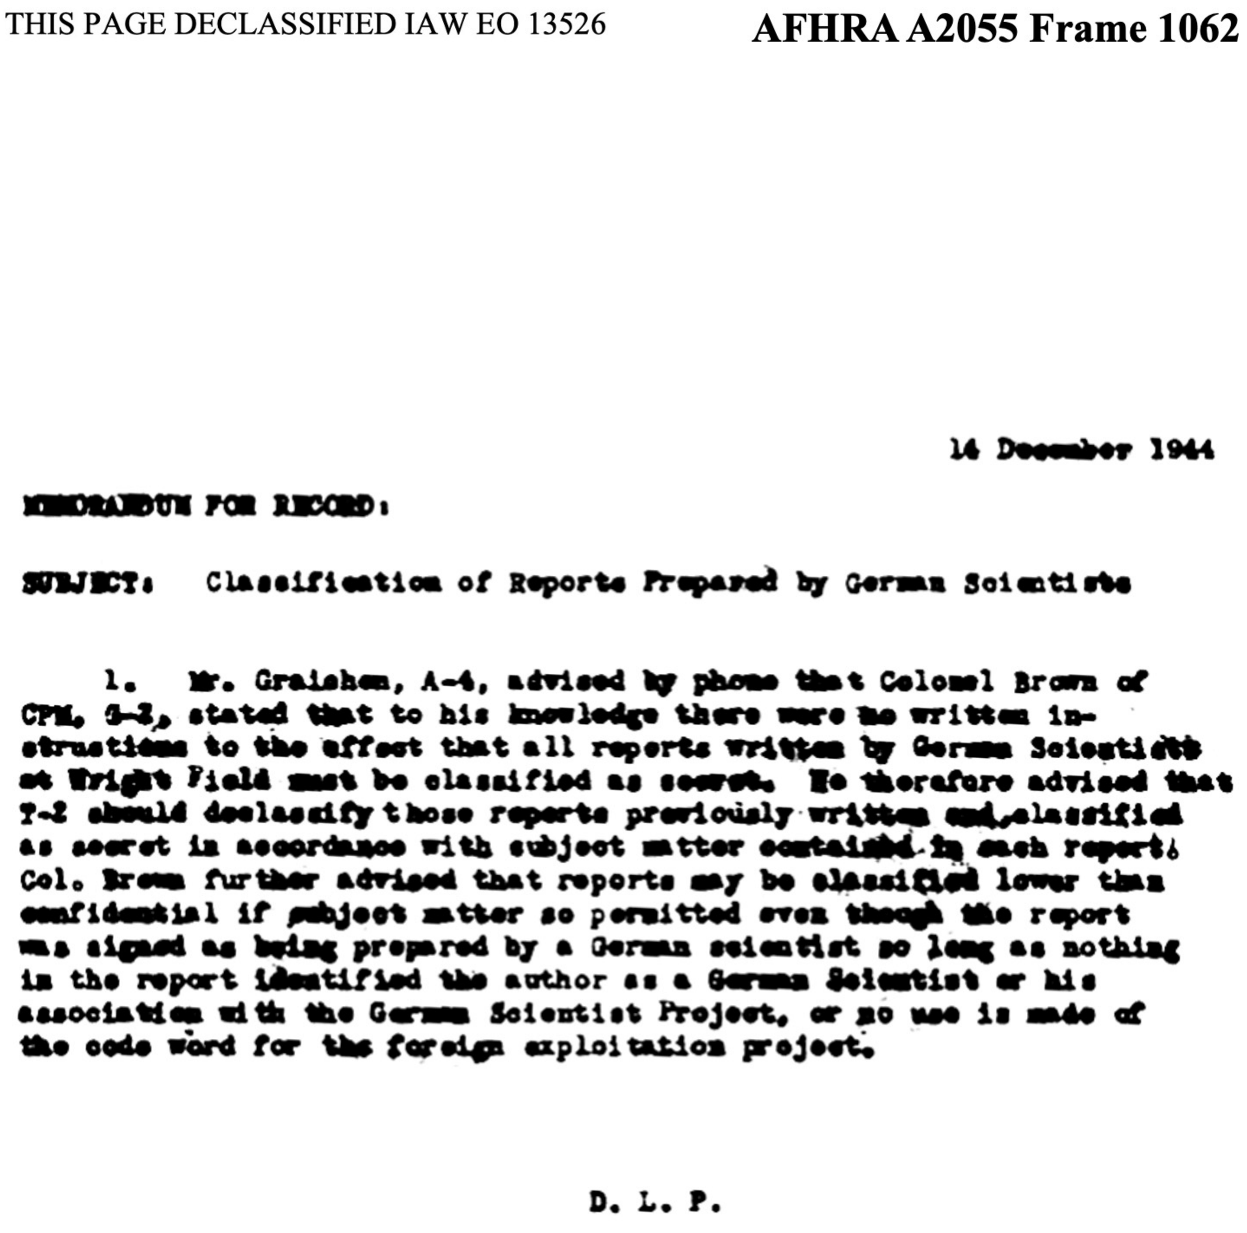
THIS FLAGPOLE IS DEDICATED TO THE VETERANS OF P.O. BOX 1142 WHO SERVED THIS COUNTRY AS MEMBERS OF TWO MILITARY INTELLIGENCE SERVICE (MIS) PROGRAMS DURING WORLD WAR II. THEIR TOP SECRET WORK HERE AT FORT HUNT NOT ONLY CONTRIBUTED TO THE ALLIED VICTORY, BUT ALSO LED TO STRATEGIC ADVANCES IN MILITARY INTELLIGENCE AND SCIENTIFIC TECHNOLOGY THAT DIRECTLY INFLUENCED THE COLD WAR AND SPACE RACE. THE MIS-X PROGRAM COMMUNICATED WITH AMERICAN MILITARY PERSONNEL HELD CAPTIVE BY THE ENEMY AXIS FORCES AND ATTEMPTED TO COORDINATE THEIR ESCAPE. THE LARGER MIS-Y PROGRAM CARRIED OUT THE INTERROGATION OF NEARLY 4,000 ENEMY PRISONERS OF WAR AND SCIENTISTS WHO WERE PROCESSED AT THIS CAMP.

Figure 11.2: From 1942 until 1946, the United States operated "P.O. Box 1142," a highly secret interrogation camp for thousands of captured German and Austrian scientists, engineers, and military personnel at Fort Hunt, Virginia. See p. 4883.



THIS PAGE DECLASSIFIED IAW EO 13526 **AFHRA A2055 Frame 1062**

14 December 1944

MEMORANDUM FOR RECORD:

SUBJECT: Classification of Reports Prepared by German Scientists

1. Mr. Graishen, A-4, advised by phone that Colonel Brown of CPM, G-2, stated that to his knowledge there were no written instructions to the effect that all reports written by German Scientists at Wright Field must be classified as secret. He therefore advised that T-2 should declassify those reports previously written and classified as secret in accordance with subject matter contained in each report. Col. Brown further advised that reports may be classified lower than confidential if subject matter so permitted even though the report was signed as being prepared by a German scientist so long as nothing in the report identified the author as a German Scientist or his association with the German Scientist Project, or no use is made of the code word for the foreign exploitation project.

D. L. P.

Figure 11.3: Beginning in 1944 (or earlier), captured German and Austrian scientists were put to work at Wright Field to transfer their detailed technical knowledge to the United States, as demonstrated by this 14 December 1944 memo from Colonel Donald L. Putt [AFHRA A2055 Frame 1062].

As has already been quoted in Chapter 1, a 1946 U.S. Senate report on the establishment of the National Science Foundation noted that the greatest scientific accomplishments of the United States during World War II were directly derived from earlier German innovations [NSF 1946, p. 6]:

> It should be somewhat humiliating to us to realize that the revolutionary sulfa drugs had their beginning in German research laboratories; that atom splitting was discovered in Berlin; that the basic pioneer work that has led to radio and radar and the enormous American electronic industries was that of a German professor. Penicillin came from England [where it was purified by Ernst Chain, a German refugee]; DDT from Germany and Switzerland.

In October 1945, Howland Sargeant and James Markham from the U.S. Office of the Alien Property Custodian testified before the U.S. Senate and provided much more detail on how extensively the United States used scientific knowledge from German patents, journals, and books during the war [Sargeant and Markham 1945, pp. 675–676, 692–695]:

> Testimony of Howland H. Sargeant, Chief, Division of Patent Administration, Office of the Alien Property Custodian
>
> Since March 1942 the Office of Alien Property Custodian has been administering thousands of patents and patent applications and other forms of industrial property vested from nationals of enemy and enemy-occupied countries. One of the first problems which confronted the Custodian after the entry of this country into World War II was the seizure and administration of patent property owned by the enemy. At that time we knew very little about the problem. We knew only that the enemy, particularly the Germans, owned great numbers of United States patents and that the inventions covered by these patents should be brought into full use in our war program. [...]
>
> Our primary objective in the administration of industrial property has been to make it available readily and immediately to serve all American industry and science. We intended to foster the active use of the store of technical knowledge represented by these patents and applications for patent; and we wanted to encourage further research on these inventions. [...]
>
> The figures we have show, Mr. Chairman, that about 33,000 of the patents that we took over were enemy-owned. [...]
>
> James E. Markham, Alien Property Custodian.
>
> Report on Alien Property Custodian Program of Reproduction of Foreign Scientific Periodicals
>
> [...] The Office of Alien Property Custodian was created to seize enemy property in this country and to administer it for the benefit of the United States. One valuable property of enemies was the right to control, through copyrights and otherwise, the distribution of much enemy-originated scientific literature. Acting under the authority given him, the Custodian has seized these rights and, through a program of periodical republication, has made available to American scientists throughout the war much of the results of

the results of German technical research, both that published just before the war and that published during it. [...]

During the war it was necessary to obtain and use information regarding activities of the enemy along scientific lines just as it was necessary to know what his military activities were. Scientific research in Germany was far advanced; recently a group of eminent American scientists stated:

"If Hitler had prevented the publication in 1939 of the first papers on atomic fission, Germany might have remained for a certain period of time in exclusive possession of a true fundamental secret of atomic power."[1]

> [1] Statement of Drs. David L. Hill, Eugene Rabinowitch, and John A. Simpson, Jr., prepared at the direction of the executive committee of the Atomic Scientists of Chicago and quoted in Life magazine October 29, 1945.

American experts in the scientific field needed ready access to foreign scientific information to buttress scientific research in this country and to keep informed of the results of such research in enemy countries. Scientific literature from enemy countries was in such demand before the war that industrial and research organizations, scientific societies, and libraries annually spent approximately one and one-half million dollars for foreign books and journals. Most of this was spent for German publications. [...]

It was, of course, reasonable to expect that the enemy journals would not reveal exact specifications for the latest antiaircraft equipment or give detailed descriptions of such weapons as the V-1 or V-2 bomb. It is clear, however, from the nature and quality of the materials printed that the German Government throughout the war continued and in some cases even intensified its peacetime policy of encouraging publication of scientific information. The advantages of this kind of dissemination, within Germany and territory occupied by the German Government, as a means of expanding scientific frontiers were obviously considered by the German Government to outweigh the possibility that such information would become generally available to scientific personnel among the enemies of the Reich. The benefits of basic German research in many fields were thus made available to American science. In some cases materials in enemy journals have been of direct and immediate use in military operations. For example, an article in VDI Zeitschrift, concerning engineering problems in constructing German camps was directly utilized in construction of Army barracks.

More frequently, however, the subject matter in the articles served primarily to reveal the trend of enemy research and basic facts which confirmed previously held theories, thus saving thousands of man hours of painstaking investigation. Moreover, such materials presented theories and concepts which were tested on the basis of American experience, and thus became valuable in the war effort. To illustrate, frequent articles in Die Naturwissenschaften and Zeitschrift fuer Physik concerning atomic fission and uranium 238 were effectively utilized by scientists engaged in the Manhattan district project. The editor of Chemical Abstracts, Dr. E. J. Crane, has informed us "There is not the least doubt in my mind of the fact that your republication program was one of the factors which made the atomic bomb possible." Iowa State College reports "This college has received an E [Excellent rating] for its research on the atomic bomb . . . The

> men working on this splitting of the atom used, to a considerable extent, the periodicals which you have reprinted."
>
> The journals reproduced dealt with almost every phase of scientific development of interest to a nation at war. Included among the journals were the leading periodicals in the following fields:
>
> Acoustics
> Aluminum
> Aviation
> Biochemistry
> Ceramics
> Chemistry
> Crystallography
> Electronics
> Engineering
> Enzymology
> Explosives
> Fermentation
> Geology
> Geophysics
> Infectious diseases
> Immunology
> Instruments
> Magnesium
> Mathematics
> Mechanical engineering
> Metallurgy
> Microscopy
> Mineralogy
> Mycology
> Nutrition
> Oils and fats
> Paper chemistry
> Parasitology
> Pathology
> Petroleum
> Pharmacology
> Physics
> Plant pathology
> Plastics
> Rubber
> Spectrochemistry
> Steel and iron
> Textiles
> Virus research
>
> [...] No report concerning reproduction of scientific materials originating in enemy countries after 1941 would be complete without reference to books as well as journals. Scientific books published in Germany in 1941, 1942, 1943, and 1944 were surreptitiously obtained by the Office of Strategic Services. Reproduction of the books was licensed to commercial publishers on a basis calculated to encourage the most extensive publication and dissemination. Nearly 700 works were licensed for republication. The books concerned subjects of direct interest to those engaged in war activities, including analysis of gases, analysis of metals, atomic fission, ballistics, electric amplifiers, electrolytes, electron emission, food analysis, magnesium, magnetic measurement, optics, organic chemistry, sound waves and measurement, synthetics and many others. A list of all books licensed, including those of recent date, is attached as an exhibit. It is noted that the prices charged are substantially less than prewar prices. For example, volumes of Beilstein's Handbuch der Organischen Chemie, which would normally have sold for \$60 before the war, are currently sold for \$12. The books were sold principally to industrial concerns, government agencies and research institutions throughout almost all the allied nations.

Influence on the structure of the U.S. research system during the Third Reich

Many of the general practices that had made the German-speaking world so effective at producing revolutionary creations were at least temporarily adopted by the United States research system, and played a vital role in the successes of its wartime R&D programs. For example, prior to 1940 the United States had little government funding for research, and any government-run laboratories were both small and rare. Beginning in 1940, the United States adopted the German model of large-scale government funding for innovative projects that could be carried out by a combination of new government labs, close ties to industry, and scientists in university laboratories. These general practices are discussed in much more detail in Section 11.2.

11.1.3 After the Third Reich

The largest and yet probably the least well understood (from the modern public's perspective) innovation transfer occurred at the end of the Third Reich. Many thousands of German-speaking scientists and engineers, well over 111,000 tons of German research documentation, more than 750,000 patents, many hundreds of complete factories and laboratories, and untold amounts of supplies, equipment, and prototypes were appropriated by the United States, the Soviet Union, the United Kingdom, France, and other countries after the war, seeding the modern world with a vast array of creations, even as it forgot the names of most of their creators.

Although this massive technology transfer has been nearly forgotten, it was loudly announced and praised by Allied governments and journalists at the time. As just one example among many, *The American Magazine* described "The World's Greatest Treasure Hunt" in its February 1946 issue [Josephs 1946]:

> Those assigned to comb Germany for hidden secrets of weapons, oil production, raw materials, synthetics, engineering, and chemical processes had the same kind of top-priority search orders as the financial treasure hunters, with the added drama of realizing they were taking part in a neck-and-neck race for secrets such as that of the atomic bomb and radar.
>
> One group, in fact, discovered a highly important German system of radar camouflage, consisting of anti-radar coverings and coatings to be employed on submarines and other weapons. When they reached the manufacturing plant they found it practically destroyed. Uncertain whether the device was already in use or had been given to the Japs, the searchers feared they were too late. Then one man came across a file of incoming shipments. That was the clue they needed. By going to the sub-assembly plants and obtaining samples, they were able to piece together the vital data and, within 24 hours, break the secret.
>
> Scientific information sleuths, like Col. Ernest L. McClendon, uncovered vital information, as when he shrewdly tracked down the files of the Berlin Patent Office secreted in a small provincial town. Others also located Nazi plans hidden in the beds of rivers and lakes, on mountaintops, and interspersed within the leaves of poetry books in the library of the University of Munich, which had been moved and hidden in the farming village of Kirchdorf.
>
> In more than 2,000 visits to captured laboratories, factories, and other key spots, our men have so far been able to obtain data showing how the Germans, among other things:
>
> — Had contemplated a piloted missile with a possible range of 3,000 miles which envisaged commercial applications for 17-minute transatlantic passenger crossings.
>
> — Were working on a formula for new war gases they hoped would prove more deadly than any chemical agent yet developed.

— Had perfected a highly advanced jet engine and plans for rocket-assisted plane take-offs. Planes with ceilings higher than our best and V-type weapons far more powerful than those used against England were in their final stages. So were designs for various secret types of guns, gunsights, novel gear and transmission construction, and air-cooled Diesel engines.

— Had specifications and construction details for naval vessels exceeding our largest, and for one-man submarines with high under-water speeds and apparatus for sustained under-water work.

— Had found new uses for many staples. For example, coal. From it they were making synthetic butter, beverage and industrial alcohol, aviation lubricants, soap, and gasoline. And they had improved techniques for the production of synthetic petroleum products and high-grade nitrocellulose from lower-grade wood pulp.

Postwar émigrés

After the war, thousands of scientists in Germany were legally forbidden from continuing to work in their previous research fields, with penalties of imprisonment with hard labor or even execution [NARA RG 40, Entry UD-75, Box 3, Folder Inter-Office Memoranda: To and From Robert Reiss]. See pp. 2052–2060. In most cases, their only options were to work for Allied countries or to do menial labor in unrelated areas.

The majority of important German-speaking scientists went to work for the United States, the Soviet Union, France, the United Kingdom, or other countries. Each of those categories is discussed in this section.

Even those scientists who remained in Germany or Austria generally had to give up their innovations when Allied countries interrogated them, seized their papers, and appropriated their scientific equipment, as also covered in this section. Their innovations were then copied in Allied countries while the scientists themselves often sank into poverty and obscurity, without the ability to continue their research careers.

ALLIED CONTROL AUTHORITY

CONTROL COUNCIL

Law No. 25

Control of Scientific Research

In order to prohibit for military purposes scientific research and its practical application, to control them in other fields in which they may create a war potential, and to direct them along peaceful lines, the Control Council enacts as follows:

Article I

All technical military organizations are hereby dissolved and prohibited. Equipment and buildings of a purely military character shall be destroyed or removed. Equipment and buildings having a possible peace time application may be utilized for that purpose with the permission of Military Government.

Article II

1. Applied scientific research shall be prohibited on:
   a. Any matter of a wholly or primarily military nature; or
   b. Any of the matters specified in Schedule "A" hereto.

2. Applied scientific research on any of the matters specified in Schedule "B" hereto shall be prohibited unless the written permission of the Commander of the Zone in which the research establishment is located is first obtained.

Article III

1. Fundamental scientific research of a wholly or

primarily military nature shall be prohibited.

2. Fundamental scientific research which is not of a wholly or primarily military nature shall be prohibited only insofar as it requires for its conduct installations which, on account of their size or their special or peculiar construction, would be valuable for any applied scientific research of a wholly or primarily military nature.

Article IV

1. Scientific research not prohibited by Article II or III of this Law may be conducted only by a research establishment authorized by the appropriate Zone Commander.

2. Subject to the provisions of this Law, the Zone Commander may take all steps, including inspection, and issue all regulations, which he may consider necessary to ensure effective control of the research establishment.

Article V

1. Each authorized research establishment shall submit to the appropriate Zone Commander the following reports:

a. Technical reports every four months showing details of all its activities, with sufficient data to enable competent persons to verify the correctness of the results reported, together with all publications of the establishment and a complete report listing the title of each problem studied, its scope, possible applied uses,

sources of funds, amount of funds expended, and the person in charge, and any other matter required from time to time by the Zone Commander.

b. Annual reports in as non-technical language as possible covering all work done in the year.

c. A complete statement of the plant, apparatus and equipment existing in the research establishment, as may be required by the Zone Commander.

2. A research establishment shall file with the Zone Commander a written notification, including a description of the proposed work and its potentialities, before instituting permitted research of the following types:

a. Fundamental scientific research on matters specified in Schedule "A" or "B".

Article VI

1. All research and technical personnel employed in a research establishment shall be registered with the appropriate Zone Commander in accordance with regulations issued by him.

2. Senior officials or scientists who were members of the National Socialist German Workers' Party (N.S.D.A.P.) or members of other Nazi organizations with more than nominal participation in its activities shall be removed and their replacement effected only by persons with suitable political records. Scientific work in general or on the development of weapons in the past shall not, in itself, be regarded as ground for dismissal or other punishment.

Article VII

In this Law -

a. "Applied scientific research" means:

(i) research work directed to the conversion to industrial use of any old or new scientific knowledge or principle; or

(ii) the conversion to pilot plant or engineering development stage of any results of fundamental scientific research; or

(iii) research work directed to the improvement of a known industrial process of manufacture or engineering or to the introduction of a new process of production of any manufactured articles; or

(iv) field and other practical trials of new devices and the testing of preproduction models.

b. "Fundamental scientific research" means research of an exploratory character in any field directed towards the discovery of new knowledge, theories, principles or laws of nature, or of new compounds or materials.

c. "Research establishments" indludes any research unit, and any university, Technische Hochschule, institute, industrial company and other agency containing a research unit.

Article VIII

Without prejudice to the liability of any other person under this Law, the responsibility for compliance therewith shall rest upon any person in charge of the research establishment as well as any person in charge of any unit thereof.

Article IX

Any person, organization, or group of persons violating any provision of this Law shall be liable to criminal prosecution in a Military Government Court.

Article X

1. Any person violating any provision of this Law shall be subject to one of the following penalties, with or without confiscation of property, in whole or in part:-
    a. Imprisionment (Gefängnis) for a term not exceeding five years;
    b. Hard labor (Zuchthaus) for a term of not less than one year and not more than fifteen years;
    c. In serious cases, hard labor for life, or death.
2. Any organization or research establishment violating any provision of this Law may be dissolved and its property confiscated, by order of the court.

Article XI

This law shall come into force on the date of its publication. Done at Berlin the 29th day of April 1946.

CONTROL COUNCIL LAW NO. 25

SCHEDULE "A"

Prohibited Applied Scientific Research

(i) Applied nuclear physics.

(ii) Applied aerodynamics, aeronautical structural engineering and aircraft power plants.

(iii) Rocket propulsion, jet propulsion and gas turbines.

(iv) Applied hydro-dynamics, particularly underwater acoustics and marine propulsion.

(v) Ship construction and the behavior of ships.

(vi) Electromagnetic, infra-red and accoustic radiation which has as its purpose:

(a) the detection of objects or obstacles; or

(b) the determination of the position of vehicles, aircraft, ships, submarines or missiles; or

(c) the remote and the automatic control of vehicles, aircraft, ships, submarines or missiles; or

(d) the destruction of living matter, except for specifically medicinal and public

health purposes.

(vii) All electronic methods of coding and the achievement of speech security.

(viii) The chemicals specified in Schedule C.

(ix) The methods of manufacture (but not the methods of utilization) of the chemicals specified in Schedule D.

CONTROL COUNCIL LAW NO. 25

SCHEDULE "B"

Applied Scientific Research Requiring Prior Permission

(i) Electromagnetic, infra-red and accoustic radiation which has as its purpose:

(a) communication of intelligence by telephony or telegraphy; or

(b) provision of public broadcast or television services; or

(c) location of fixed transmitters by direction finding methods; or

(d) other applications not banned under Schedule "A".

(ii) Valves, tubes or other devices which employ emission of electrons, either thermionic or from cold surfaces.

(iii) Industrial explosives.

(iv) Ball and roller bearings.

(v) Ammonia and methanol produced by high pressure hydrogenation.

(vi) Synthetic oil.

(vii) Radioactivity other than for medical purposes.

(viii) Synthetic rubber.

(ix) The methods of utilization of the chemicals specified in Schedule "D".

SCHEDULE "C"

Chemicals on Which Applied Scientific Research is Prohibited

High explosives.

NOTE: By "high explosives" is meant organic explosives used as fillings for shells, bombs, etc.

Double-base propellants (i.e. nitrocellulose propellants

containing nitro-glycerine, diethyleneglycol dinitrate or analogous substances).

Single-base propellants

Nitroguanidine

Nitroglycerine

Initiating explosives

Dinitrotoluene

Poison war gases (including liquids and solids customarily included in this term) with the exception of:

Chlorine
Phosgene
Hydrocyanic acid
Chlorinated ketones
Halogenated carboxylic acids and their esters
Cyanogen halides
Lachrymatory halogen derivatives of hydrocarbons

Rockets fuels: - Hydrogen peroxide of above 50% concentration
Hydrazine hydrate
Methyl nitrate

Highly toxic products from bacteriological or plant sources (with the exception of those bacteriological and plant products which are used for therapautic purposes).

Figure 11.12: After the war, thousands of scientists in Germany were legally forbidden from continuing to work in their previous research fields, with penalties of imprisonment with hard labor or even execution. In most cases, their only options were to work for Allied countries or to do menial labor in unrelated areas [NARA RG 40, Entry UD-75, Box 3, Folder Inter-Office Memoranda: To and From Robert Reiss].

Beginning in 1945, more than 1600 German-speaking scientists and engineers were brought to the United States by Operation Paperclip, which in its earliest phases was also called Operation Overcast [Linda Hunt 1991, p. 1]. Many hundreds more were brought by at least two other Paperclip-related programs, Project 63 and National Interest [Linda Hunt 1991, pp. 1, 200], so the total number of German-speaking specialists bought to the United States in the late 1940s was well over 2000 people. In 1956, U.S. Ambassador to West Germany (and former Harvard president) James Conant described Paperclip as "a continuing U.S. recruitment program which has no parallel in any other Allied country" [NARA RG 59]. By 1966, at least 6000 German-speaking scientists and engineers had moved to the United States [Mick 2000, p. 316]. U.S. recruitment of German-speaking scientists and engineers through these programs continued until at least 1973, nearly three decades after the end of World War II, despite official protests from West Germany and official denials from the United States [Linda Hunt 1991, pp. 141, 221–222].

Tom Bower, who wrote a detailed exposé of the Paperclip program, described the origins of the program and the technological superiority of the German-speaking scientists it brought to the United States [Bower 1987, pp. 3–6]:

> During the cataclysmic life span of the Third Reich, [Wernher] von Braun, [Hubertus] Strughold, and twenty thousand German scientists had revolutionized the weapons of warfare. Twenty-five years later [in the manned moon landings], the Americans were reaping the benefit of their former enemies' youthful genius. [...]
>
> Their recruitment after the war had followed interrogation by American officers. After selection, the chosen German scientists were identified simply with an ordinary paperclip on their personal file. [...]
>
> The fact that all the four Allies—the Americans, the British, the Russians, and the French—became involved in the frantic and at times ruthless competition for German scientists is particularly surprising when one realizes that the use of the Germans was simply not contemplated until as late as 1945. [...]
>
> The answer to the riddle starts in the prewar years, when European engineering students learned German as a second language so that they could read the important scientific literature published by one of the world's industrial giants and its leading technical innovator. It was no coincidence that many of the scientists developing the American atomic bomb in Los Alamos had Teutonic names. Von Braun's rockets were the symbol of Germanic superiority. The substance was considerably broader—in engineering, chemical processes, and industrial design—but, before 1940, this was not appreciated by either the American or British military.
>
> At the outbreak of war, complacent military chiefs and politicians in Washington and London misunderstood the nature of the conflict into which they had been cast. In Berlin, scientists and engineers were the welcome allies of politicians and military chiefs. But in London and Washington the government, the civil service, and the military chiefs largely ignored or even disdained the purveyors of technical information. Allied officers, startled by Hitler's momentous conquests, only gradually stumbled to the realization that their Achilles heel was the technical inferiority of many of their guns, planes, tanks,

and submarines. On the eve of Hitler's final defeat, Allied scientists had narrowed the lead and occasionally overtaken their enemy, but in crucial areas Germany's superiority, even in the last year of the war, had actually increased. Acknowledgment of that reality bred a conviction—some would say a legend—of German scientific supremacy that was not far from the truth. [...] The proof of German technical prowess is overwhelmingly established in the hundreds of reports written by Allied investigators who did not shy from describing the Germans' "astonishing achievement" and "superb invention." It was also established by the very survival of Germany during four years of total war despite the prediction during the first two years of war by British intelligence that the German economy and German industry faced imminent and total collapse. The blockade on essential minerals, chemicals, and petroleum products, it was argued, would cripple weapons production. But the very opposite happened, because German scientists developed an astonishing range of substitutes that not only humiliatingly neutralized the Allied blockade but heralded the dawn of a new scientific era. [...] German scientists had pioneered so many inventions that many Allied experts would complain that their plunder could do no more than scratch the surface.

Since 1945, the genesis of weapons by all four Allies has been dominated by the inheritance of Germany's wartime inventions. Indeed, the Korean War can be viewed, on the technical level, as a trial of strength between two different teams of Germans: those hired by America and those hired by the Soviet Union. The aerial dogfights between Soviet MiG-15s and American F-86 Sabres—both designed by German engineers—dispelled for many their doubts about the expediency of plundering Germany's scientific expertise.

As the war ended, Allied investigators, plunged into the hectic race to find their German competitors, were in turn shocked, excited, and then bewildered as they began to appreciate their own technical ignorance. For them, a haphazard series of interrogations conducted in the turmoil of a distraught and defeated nation was tantalizing and frustrating. The obvious solution was to transport the German experts to America and Britain, following the example of the French and Russians. The American haul, enthusiastically hailed as an Aladdin's cave, was worth alone, according to some American military estimates, "thousands of millions of dollars."

Figure 11.13: Examples of German-speaking creators who emigrated to the United States after the Third Reich.

John Gimbel, who wrote the definitive book on postwar technology transfer, further described the widespread impact that the Paperclip scientists ultimately had in the United States [Gimbel 1990a, pp. 171–172]:

> As we have also seen, the armed services shared their Paperclip specialists with their contractors, on occasion permitting them to shuttle from military installations to private firms and in many instances ultimately releasing them entirely for employment in the private sector. A Joint Intelligence Objectives Agency (JIOA) statistical report of 1951, for example, shows Paperclip specialists working in a variety of private firms and agencies, among them Bendix Aviation Corporation, Grumman Aircraft Company, Packard Motor Company, Hydropress, Incorporated, of New York, Phillips Petroleum Company, Dow Chemical Company, Hydrocarbon Research, and the Universities of Indiana, Chicago, Minnesota, Illinois, Missouri, and others. Clarence G. Lasby, in his pioneering study of Project Paperclip, published in 1971, listed numerous universities (Yale, Wisconsin, Kansas, Ohio State, and others) and corporations (Boeing, Raytheon, General Electric, Bell, Westinghouse, and others) to which Paperclip specialists had gone in the 1950's and 1960's, "frequently in executive positions."

For additional examples of the contributions of Paperclip scientists, see pp. 4890–4892.

Figure 11.13 shows one group of Paperclip scientists (aerospace engineers including Wernher von Braun right of center in the front row) at Fort Bliss, Texas, in 1946.

In addition to thousands of scientists and engineers, the United States and other countries also acquired many of the administrators who had selected, funded, and managed the science and engineering programs. One of the most spectacular examples is that Dr. Ing. Hans Kammler, an SS general who ended up controlling almost all of Germany's advanced weapons programs by the end of the war, was captured by the United States and interrogated at great length after the war; see pp. 4931–4959.

The Soviet Union forcibly removed and held thousands of German-speaking skilled scientific workers (the exact numbers are even murkier than the corresponding figures for the United States), and millions of German-speaking unskilled workers.[1]

The German historian Christoph Mick was able to access some relevant files in Moscow archives for the first time in the 1990s. He reported that he had found documentation for at least 3000 German and Austrian scientists and engineers who had been transferred to the Soviet Union during the period 1945–1947 [Mick 2000, pp. 15–17]:

Zwischen 1945 und 1947 wurden deutsche und österreichische Wissenschaftler, Techniker und Facharbeiter in die Sowjetunion gebracht, um in Werken, Konstruktionsbüros und Forschungseinrichtungen qualifizierte Arbeit zu verrichten. [...]	Between 1945 and 1947 German and Austrian scientists, technicians and skilled workers were brought to the Soviet Union to carry out qualified work in factories, design offices and research facilities. [...]
Es handelte sich um etwa 3.000 Wissenschaftler, Ingenieure, Techniker und Facharbeiter, zusammen Angehörigen nicht mehr als 8,000 Personen. [...]	There were about 3,000 scientists, engineers, technicians and skilled workers, together with relatives no more than 8,000 persons. [...]
Nach Art und Zeitpunkt der Rekrutierung können fünf Typen von Spezialisten unterschieden werden.	Five types of specialists can be distinguished according to the type and time of recruitment.
1. Die erste Gruppe wurde zusammen mit ihren Familien bereits im Sommer 1945 per Flugzeug in die Sowjetunion gebracht. Angesichts der Zeitumstände kann von einer freiwilligen Wahl keine Rede sein, doch ist kein Fall bekannt, in dem physische Gewalt angewandt wurde. Diese erste Welle betraf vor allem die Atomforscher, es handelt sich um weniger als 100 Personen. Darunter fallen der Privatforscher Manfred von Ardenne, der Physiknobelpreisträger Gustav Hertz, der ehemalige Leiter der Forschungsabteilung der Auer-Gesellschaft, Nikolaus Riehl, und der Direktor des Kaiser-Wilhelm-Instituts für physikalische Chemie in Berlin, Peter Adolf Thiessen.	1. The first group and their families were brought to the Soviet Union by plane as early as summer 1945. Given the circumstances, there was no voluntary choice, but there was no known case of physical violence. This first wave mainly affected nuclear researchers, fewer than 100 people. These include the private researcher Manfred von Ardenne, the Nobel Prize winner in physics Gustav Hertz, the former head of the research department of the Auergesellschaft Nikolaus Riehl, and the director of the Kaiser Wilhelm Institute for Physical Chemistry in Berlin, Peter Adolf Thiessen.
2. Die zweite und mit Abstand größte Gruppe wurde am 22. Oktober 1946 zwangsweise in die Sowjetunion gebracht. Davon betroffen waren etwa 2.200–2.300 Familien, insgesamt 6.700–7.000 Personen. Die Fachleute stammten vor allem aus den Bereichen Flugzeugzellen- und Flugzeugtriebwerksbau, Optik, ballistische und Lenkraketen, Chemie, Elektrotechnik und Marinewaffen.	2. The second and by far the largest group was forcibly brought to the Soviet Union on 22 October 1946. About 2,200–2,300 families were affected, a total of 6,700–7,000 people. The experts came mainly from the fields of airframe and aircraft engine construction, optics, ballistic and guided missiles, chemistry, electrical engineering and naval weapons.

3. Die dritte Gruppe kam zwischen 1946 und 1947 ausgestattet mit Zeitverträgen in die Sowjetunion. Etwa 200–250 Fachkräfte halfen beim Wiederaufbau demontierter Betriebe und wiesen die einheimischen Arbeiter in die Funktionsweise der Maschinen ein. Diese Spezialisten waren meist in der Textil- und Chemieindustrie tätig. Dazu kamen zehn Fachleute für Marinewaffen und einzelne Chemiker und Physiker, die im Atomprojekt eingesetzt wurden.	3. The third group came to the Soviet Union between 1946 and 1947 with temporary contracts. Some 200–250 skilled workers helped rebuild dismantled factories and trained local workers in the operation of the machines. These specialists were mostly employed in the textile and chemical industries. There were also ten specialists for naval weapons and individual chemists and physicists who were employed in the nuclear project.
Diese drei Gruppen waren zwar in ihrer Bewegungsfreiheit stark eingeschränkt, galten aber nicht als Gefangene.	Although these three groups were severely restricted in their freedom of movement, they were not considered prisoners.
4. Davon unterschied sich die vierte Gruppe. Sie bestand aus Häftlingen der sowjetischen Speziallager in der SBZ, die wegen echter oder angeblicher Verstrickung in die Verbrechen des NS-Regimes interniert worden waren. Etwa 50–60 Häftlinge mit technischem Spezialwissen wurden 1946 und 1947 zur Arbeit in Konstruktionsbüros des NKVD/MVD in die Sowjetunion deportiert. Sie arbeiten zunächst im elektrotechnischen Bereich, später wurden sie bei der Entwicklung von lenkbaren Flugabwehrraketen eingesetzt.	4. The fourth group was different from those. It consisted of prisoners from the Soviet special camps in the Soviet Zone who had been interned because of real or alleged involvement in the crimes of the Nazi regime. In 1946 and 1947, about 50–60 prisoners with specialized technical knowledge were deported to the Soviet Union to work in construction offices of the NKVD/MVD. At first they worked in the electrotechnical field; later they were used in the development of guided anti-aircraft missiles.
5. Die fünfte Gruppe wurde aus Kriegsgefangenenlagern rekrutiert. Etwa 200–250 Kriegsgefangene, in der Regel Handwerker, aber auch einzelne Wissenschaftler und Ingenieure, wurden in Einrichtungen des Atomsektors gebracht, in denen bereits deutsche Wissenschaftler tätig waren.	5. The fifth group was recruited from prisoner-of-war camps. Some 200–250 prisoners of war, usually craftsmen, but also individual scientists and engineers, were brought to nuclear facilities where German scientists were already working.

It is important to note that Mick's estimate of 3000 German-speaking scientists is a minimum number. That estimate did not include specialists who were transferred to the Soviet Union after 1947, scientists and engineers who remained in Soviet-controlled East Germany and labored on behalf of the Soviet Union there, and German-speaking scientists from other areas of the former Third Reich (Poland, Czechoslovakia, etc.) who worked for the Soviet Union in those regions or were transferred to the Soviet Union. Thus the total number of German-speaking scientists recruited by the Soviet Union would have been many thousands.

For example, after German reunification, the Stanford University historian Norman Naimark studied some former East German records that described over 6000 specialists who remained in East Germany to work there on behalf of the Soviet Union [Naimark 1995, pp. 230–232]:

> The Soviets removed most of the scientists and technicians important to their armaments industry in the October 22 [1946] operation, and they took others periodically by a variety of means from Western and Eastern zones. [...] But Soviet technical experts understood that they still had a lot to gain in the way of knowledge and expertise from the high level of German technological achievements, industrial infrastructure, and production methods in the Eastern zone. [...] An Administration for the Study of Science and Technology in Germany was attached to SVAG headquarters in Karlshorst. This central administration was to supervise a network of Science and Technology Offices (NTOs) in each of the provinces and many of the large cities in the Eastern zone. [...]
>
> Altogether in the NTOs, 611 Soviet specialists oversaw the work of 6,014 German scientists and technicians, plus 7,067 German workers. Between 1946 and 1948, the NTOs supervised the completion of 7,069 projects, some of which had great practical value for Soviet industry. From German specialists the Soviets learned how to make high-octane gas and carbon fuels. They learned how to produce liquid fuels and build turbines that could be run on liquid fuels. They created a Soviet nylon industry from German accomplishments in that field, and adapted the Buna chemical factories' advancements for the creation of synthetic rubber. Similarly, the technology of the German coal briquette industry was adapted for Soviet use[...] Other Soviet industries that benefited in particular from German technologies developed by the NTOs included ceramics, metal finishing, film developing, and metal plating. Almost 4,000 prototypes of a variety of machines, production stations, and technologies were transferred to the Soviet Union in this period, through the NTOs.

In 1946 in just one Soviet-occupied former German underground factory alone, 2000–3000 German scientists were reported to currently be working for the Soviet Union, continuing wartime German work on nuclear weapons and rockets (p. 3697).

For examples of contemporary articles documenting the transfer of German and Austrian scientists to the Soviet Union, see:

> Russian Seizures [of Austrians] in Austria Aired [NYT 1945-11-22 p. 16].

Similarly, large numbers of German-speaking scientists and engineers were recruited by France.[2] Writing for *L'Express*, investigative journalists Vincent Nouzille and Olivier Huwart sifted through government records and described the recruitment and ultimate technological impact of over 1000 German and Austrian scientists and engineers in France after the war [Nouzille and Huwart 1999]:

> Entre 1945 et 1950, plus de 1 000 chercheurs allemands, dont certains nazis, ont été “embauchés” par les autorités françaises. Un apport très secret à la reconstruction de l'industrie militaire et aéronautique du pays. [...]
>
> Plus étonnant: le LRBA n'est pas le seul organisme français à avoir bénéficié, après guerre, de ces “transferts de technologie” très particuliers. Les faits ont longtemps été masqués aux yeux de l'opinion pour cause d'orgueil national et de secret défense. Mais, depuis quelques années, une poignée d'historiens et d'initiés ont commencé de découvrir une réalité insoupçonnée: entre 1945 et 1950, la France a massivement recruté des “cerveaux du IIIe Reich”. Combien? En recoupant ces études avec les archives accessibles et des témoignages directs, L'Express peut avancer qu'ils furent plus d'un millier. Soit nettement moins que les 5 000 savants allemands enrôlés par l'URSS ou les 3 000 recrutés par les Etats-Unis dans le cadre de leur opération “Paperclip”. Mais plus que les quelques dizaines embauchés en Grande-Bretagne. Des nazis? Nombre de ces savants n'étaient, semble-t-il, ni des fanatiques ni des militants. “J'étais un simple ingénieur, sans engagement politique”, dit Kraehe. Toutefois la France, on le verra, ferma les yeux pour attirer quelques figures au passé chargé. Ces recrues avaient-elles un bon niveau de connaissances? “Oui, estime Jacques Villain, historien de la SEP, spécialiste du sujet. La France, principalement dans le domaine aéronautique et militaire, a su attirer des personnalités de premier plan.”

> Between 1945 and 1950, more than 1,000 German researchers, including some Nazis, were “hired” by the French authorities. A highly secret contribution to the reconstruction of the country's military and aviation industry. [...]
>
> More surprisingly, the LRBA is not the only French organization to have benefited after the war from these very specific “technology transfers.” For a long time, the facts were hidden from the eyes of the public because of national pride and military secrecy. But in recent years, a handful of historians and insiders have begun to discover an unsuspected reality: between 1945 and 1950, France massively recruited the “brains of the Third Reich.” How many? By cross-checking these studies with accessible archives and direct testimonies, L'Express can state that there were more than a thousand of them. This is considerably less than the 5,000 German scientists recruited by the USSR or the 3,000 recruited by the United States as part of their “Paperclip” operation. But more than the few dozen hired in Great Britain. Nazis? Many of these scientists were, it seems, neither fanatics nor militants. “I was a simple engineer, without political commitment,” Kraehe says. However, France, as we will see, closed its eyes to attract some figures with a busy past. Did these recruits have a good level of knowledge? “Yes,” says Jacques Villain, SEP historian and specialist in the subject. France, mainly in the aeronautics and military sectors, has been able to attract leading personalities.”

[2] Defrance 2001; Ludmann-Obier 1986, 1988, 1989; Hans-Ulrich Meier 2010; Nouzille and Huwart 1999; O'Reagan 2019; Teyssier and Hautefeuille 1989; Trichet 2009.

Les noms de ces têtes de file sont inconnus du grand public: Jauernick, Müller, Bringer, Habermann pour les fusées (LRBA et SEP); Oestrich pour les moteurs à réaction à la Snecma [...]; Sänger pour les engins spéciaux à l'arsenal de Châtillon (aujourd'hui Aerospatiale); Schardin et Schall pour les explosifs à l'institut Saint-Louis (ministère de la Défense). A ces leaders il faut ajouter des apports d'équipes allemandes chevronnées—réparties sur tout le territoire [...]—dans le domaine des hélicoptères, des sous-marins, des torpilles, des radars, des moteurs de char, des obus, des souffleries aéronautiques. Et même de la force de frappe[...]

La liste est loin d'être close: "La dispersion des archives et leur fréquente classification militaire empêchent encore d'avoir une vision complète du phénomène, estime Gérard Bossuat, professeur d'histoire à l'université de Cergy-Pontoise, spécialiste des relations franco-allemandes d'après-guerre [3]. Mais une chose est sûre: ce recrutement de savants a été assumé politiquement par le gouvernement et organisé administrativement." Même si la plupart sont repartis en Allemagne dans les années 50, Emmanuel Chadeau, professeur d'histoire à l'université Lille III, estime que "leur présence a permis à certains secteurs de l'industrie française de rattraper au moins cinq ans de retard, voire de réaliser de belles percées". De quoi réviser quelques vérités... [...]

The names of these leaders are unknown to the general public: Jauernick, Müller, Bringer, Habermann for rockets (LRBA and SEP); Oestrich for Snecma jet engines [...]; Sänger for special vehicles at the Châtillon arsenal (now Aerospatiale); Schardin and Schall for explosives at the Saint-Louis Institute (Ministry of Defense). To these leaders must be added the contributions from experienced German teams—spread throughout the country [...]—in the field of helicopters, submarines, torpedoes, radar, tank engines, shells, and aeronautical wind tunnels. And even the strike force[...]

The list is far from over: "The dispersion of archives and their frequent military classification still prevent us from having a complete picture of the situation," says Gérard Bossuat, Professor of History at the University of Cergy-Pontoise, a specialist in Franco-German postwar relations. But one thing is certain: this recruitment of scientists was politically decided by the government and organized administratively." Even though most of them returned to Germany in the 1950s, Emmanuel Chadeau, professor of history at the University of Lille III, believes that "their presence has enabled certain sectors of French industry to catch up at least five years earlier, or even to make significant breakthroughs." Something to revise some truths.... [...]

Pourtant, dans cette chasse souterraine, les Français ne se débrouillent pas mal. Les ordres viennent de très haut. Dès le 16 mai 1945, dans une note classée "très secret"—exhumée des archives de l'armée de terre par l'historienne Marie-France Ludmann-Obier—l'état-major de la Défense nationale alerte le général de Gaulle, chef du gouvernement provisoire, sur l'intérêt des recherches allemandes: "L'activité et l'ampleur des résultats obtenus, dans le domaine des armes secrètes notamment, ont vivement impressionné ceux qui les ont examinés[...]. Certaines personnalités, têtes de file, ont été emmenées en Angleterre, d'autres pressenties pour travailler en Amérique. De notre côté, nous avons emmené temporairement à Paris certaines personnalités [...]". Soucieux de redonner rapidement à la France les moyens d'une grande puissance, le général de Gaulle délivre, le 17 mai 1945, une instruction personnelle et confidentielle: "Il y aura tout lieu de transférer en France les scientifiques ou techniciens allemands de grande valeur pour les interroger à loisir sur leurs travaux et éventuellement les engager à rester à notre disposition."

Les consignes sont claires. Le général Pierre Koenig, qui assure, à Baden-Baden, le commandement en chef des forces françaises dans la zone d'occupation en Allemagne (ZFOA), s'en fait l'ardent promoteur. "Mieux vaut la qualité que le nombre", écrira-t-il en octobre 1946 dans une note secrète, conservée aux archives de la ZFOA, à Colmar. Il prône une "immigration éclairée", de savants, mais aussi de techniciens de "valeur honorable". Avec un argument de poids: "Chaque technicien qui vient se fixer à demeure en France correspond à une diminution du potentiel allemand et à une augmentation du potentiel français; il faut en profiter." Dans une autre lettre, il insiste sur cet avantage qu'il sait temporaire: "Soyons sûrs que du jour où un gouvernement allemand [...] sera reconstitué, il fera tout son possible pour arrêter cette véritable hémorragie humaine, se rendant compte du grave préjudice subi..."

However, in this underground hunt, the French did not do badly. Orders came from very high places. As early as 16 May 1945, in a note classified as "top secret"—exhumed from the army archives by the historian Marie-France Ludmann-Obier—the National Defense Staff alerted General de Gaulle, Head of the Provisional Government, to the importance of German research: "The activity and scale of the results obtained, particularly in the field of secret weapons, greatly impressed those who examined them[...] Some leading people were taken to England; others were approached to work in America. On our side, we temporarily took some people to Paris..." Eager to quickly give France back the resources of a great power, General de Gaulle issued a personal and confidential instruction on 17 May 1945: "There will be every reason to transfer to France German scientists or technicians of great value to question them at will about their work and possibly urge them to remain at our disposal."

The instructions were clear. General Pierre Koenig, who was in charge of the chief command of the French forces in Baden-Baden in the German occupation zone (ZFOA), was the ardent promoter. "Quality is better than number," he wrote in October 1946 in a secret note in the ZFOA archives in Colmar. He advocated "enlightened immigration" of scientists, but also of technicians of "honorable value." With a strong argument: "Each technician who comes to France permanently corresponds to a decrease in German potential and an increase in French potential; we must take advantage of it." In another letter, he insisted on this advantage, which he knew to be temporary: "Let us be sure that from the day a German government is reconstituted, it will do everything possible to stop this real human bleeding, realizing the serious damage suffered..."

> Malgré des moyens limités, la machine administrative française se met en marche. La "section T" laisse la place à la mi-1945 à une "section d'information scientifique" où sont représentées toutes les armes (air, terre, marine), le CNRS et le Centre national des télécoms (Cnet). Cette instance établit des centaines de rapports et rédige plus de 3 500 fiches personnelles sur des savants allemands. Le 19 mars 1946, le ministère de l'Economie nationale détaille la procédure de recrutement, soumise au feu vert de neuf services ministériels (production industrielle, finances, travail, sûreté, consulats, etc.). Une "procédure d'extrême urgence" est tout de même prévue, "dans le cas où un savant ou un technicien serait sur le point de partir à l'étranger et de nous échapper". [...]
>
> Lorsque les cibles valent la peine, tous les arrangements sont possibles. Une liste de souffleurs de verre, très prisés pour l'optique de pointe, est transmise à Paris avec cette précision: "Ces personnes résidant en zone russe [...], il serait recommandable de faire appel aux services du Sdece." Autrement dit: les services secrets français sont chargés des "exfiltrations" des autres zones d'occupation. C'est ainsi qu'en décembre 1945 Ferdinand Porsche est enlevé par des Français dans sa résidence de Zell am See, alors qu'il est surveillé par les Américains. Inventeur de la Coccinelle de Volkswagen et de l'énorme char Maus, Porsche, hitlérien fanatique, est d'abord emprisonné à Dijon, avant d'être affecté quelques mois chez Renault, où il est mal accepté, puis remis en prison.

> Despite limited resources, the French administrative machinery was set in motion. The "T section" gave way in mid-1945 to a "scientific information section" where all military services (air, land, sea), the CNRS and the National Telecommunication Center (Cnet) were represented. This body produced hundreds of reports and more than 3,500 personal files on German scientists. On 19 March 1946, the Ministry of the National Economy detailed the recruitment procedure, subject to the approval of nine ministerial departments (industrial production, finance, labour, security, consulates, etc.). An "extreme urgency procedure" was nevertheless provided for, "in the event that a scientist or technician is about to leave for a foreign country and escape from us." [...]
>
> When the targets were worth it, all arrangements were possible. A list of glassblowers, highly prized for their advanced optics, was sent to Paris with this instruction: "These people residing in the Russian zone [...], it would be advisable to use the services of the Sdece." In other words: the French secret services were responsible for "exfiltrations" from the other occupation zones. Thus in December 1945 Ferdinand Porsche was kidnapped by the French from his residence in Zell am See, while he was under American surveillance. Inventor of the Volkswagen Beetle and the huge Maus tank, Porsche, a Hitlerian fanatic, was first imprisoned in Dijon, before being posted for a few months at Renault, where he was poorly received and then put back in prison.

According to the historians of science Burghard Ciesla and Bernd Krag, the true number of German scientists and engineers working in postwar France was actually much higher than Nouzille and Huwart reported, and was at least several thousand [Hans-Ulrich Meier 2010, p. 678]:

> In 1947 the French authorities selected from the almost 100,000 German prisoners of war about 6700 men as "spécifiquement recrutés." These were mostly members of technical professions and were to work in France in different industrial areas, but also in research and development projects. German experts in the fields of rocket, missile, torpedo, engine, aircraft, helicopter, and tank development as well as experts in material science,

> navy-related fields, ballistics, and handguns were at the same time brought to France after the war. But these were by far not yet all the areas. Regarding the employment of German specialists in France, an order of magnitude of 2000 to 3000 persons may be assumed[...]

Pierre Trichet, a French aerospace engineer retired from the ONERA research center, gave further examples of the contributions of German-speaking scientists and engineers to postwar French programs [Trichet 2009]:

> The four major victorious countries of World War II, the United States, the USSR, Great Britain and France shared, to varying extents, the skills acquired by the Germans in science and technology. These scientists were fewer in number than those who went to the United states or to the Soviet Union, but they nonetheless formed an array that represented a broad spectrum of competencies. German engineers and scientists worked in the years after the war closely and successfully together with their French colleagues. A large German engineering group was initially headed by Fritz Nallinger, developed at the French engine company Turbomeca a number of small gas turbines. The ATAR engine, developed by the group of BMW engineers, headed by Hermann Oestrich, was manufactured by SNECMA in large numbers. Under the technical supervision of Hans Schneider, the newly registered company SEPR started the development of liquid fuel rocket motors. Eugen Sänger contributed as adviser to the design and layout of the French test aircraft Nord 1500 "Griffon" with a combined turbojet-ramjet engine. Under the participation of a German group of engineers, headed by Heinrich Focke, a helicopter development program was started at the SNCASE with the SE3101 which led to the successful French helicopter "Alouette". In continuation of the "Doblhoff-concept" of blade-tip propulsion, the light helicopter SO 1221 "Djinn" was developed at SNCASO under the technical supervision of Theodor Laufer. From a rebuild of the missile Fieseler Fi103 (V1), the homing missile Nord CT10 and CT20 with pulsejet, respectively turbojet engines were realized under participation of German engineers.

Likewise, large numbers of German-speaking scientists and engineers were recruited by the United Kingdom.[3] Over 1000 German-speaking scientists and engineers worked for the U.K. government or companies, either in the United Kingdom or on its behalf in West Germany [Glatt 1994]. They played important roles in postwar British developments in jets, missiles, rockets, submarines, and other areas. The U.K. government was relatively secretive about its use of these German-speaking scientists, quite possibly due to a desire to avoid public questions about employing scientists who had only recently been creating weapons that were bombarding the United Kingdom. Historian Charlie Hall described the U.K. programs for interrogating, recruiting, and exploiting German-speaking scientists [Hall 2019a, pp. 1–2, 4]:

> [...A]fter the war ended, the victorious Allies sought to continue the work of the Third Reich's rocket scientists and bring the technology of the V-2 into their own armories. [...] Under the codename Operation Backfire, this took place through the summer and autumn of early 1945 and culminated in three test-firings in October. All of these took place in the Lower Saxony coastal town of Cuxhaven and were run by the same German troops who had overseen the rocket attacks on London, albeit now under close British

---

[3] Bud and Gummett 1999; Edgerton 2006; Glatt 1994; Hall 2019a; O'Reagan 2014, 2019; Paneth 1948.

supervision. [...] Britain, through the utilisation of German technology and expertise, had now entered the ballistic missile era.

Backfire was not the only operation of its type which took place at this time, nor was rocketry the only field in which the British (and the other Allies) were interested. For instance, 125 kilometers to the south-east of Cuxhaven, at Raubkammer, near Munster, experts from the British Chemical Defence Experimental Establishment at Porton Down spent three months conducting a wide range of trials and experiments with the newly discovered German nerve agents, primarily Tabun and Sarin. Elsewhere, Operation Surgeon, run by the Ministry of Aircraft Production and the Ministry of Supply, took over several former Luftwaffe installations and set out to explore German progress in all manner of aeronautical topics. These large investigative projects which sprung up in the summer of 1945 were of huge significance, but only represent a small portion of British interest in German science and technology in the post-war period. British officials had entered Paris within a week of its liberation to explore formerly German-occupied laboratories in the French capital. Royal Navy experts were among the first Allied forces into Kiel and moved quickly to examine the submarine design and construction facilities there. After Germany surrendered, British investigators poured into the country and visited every laboratory, research site and factory of even passing interest, in their quest to learn all they could about German science and technology.

The process did not stop there. In January 1946, the first group of 23 German scientists recruited by Britain after the war arrived in Barrow-in-Furness in Cumbria, to work on submarine technology at the Vickers-Armstrong shipyard. Many more followed over the next two or three years, travelling to Britain to work on rockets, aircraft, chemical warfare, and on a huge range of civil-industrial topics as well. When the British and French launched Concorde, the world's first supersonic commercial airliner, in 1976, few knew that much of the aerodynamics work involved in its design had been completed by German experts who came to Britain as part of a government scheme in the immediate post-war period. Other German specialists did not land such significant roles in Britain after the war, but did contribute to the British military or economy in other ways, often through written reports or interrogations which took place during periods of internment at special camps in Germany and Britain after the war. Some of these individuals were not even detained because they were considered of value to Britain, but rather because it was considered important to keep them out of the employ of the Soviet Union. In this way, German science and technology became a source of much competition in the early Cold War period.

[...I]n the minds of Allied strategists, German military technology was far superior to their own and the perceived benefits to be gained by acquiring this equipment, and the expertise behind it, were extremely tempting. Thus exploitation was born. The supposedly more advanced nation had been defeated, and its victorious occupiers could now claim the scientific and technological spoils of war; their own armouries and industries could make huge leaps forward by standing on the shoulders of their newly vanquished foe. [...]

With full British government sanction, German laboratories and factories were inspected and meticulously pillaged, machinery and prototypes were confiscated, and documents

> and blueprints were shipped back to Britain in their thousands. In addition, expert German personnel were detained, interrogated and, in many cases, recruited to work for the British state or for private companies. No area of expertise was left untouched, from the most highly sensitive military project to the most mundane commercial production techniques; all was considered fair game under the terms of the British exploitation initiative.

German-speaking scientists also went to many countries other than the four major Allies. Through the British Commonwealth, at least 150 moved to Australia [Evan Jones 2002] and at least 41 to Canada [Margolian 2000]. At least 108 went to Argentina and at least 27 to Brazil [Stanley 1999]. At least ∼100 went to Spain, ∼100 to Egypt, and ∼50 to India [Neufeld 2012].

Although the numbers of German-speaking scientists working for various countries as given above are only lower bounds, and the corresponding figures for other countries (Switzerland, Sweden, South Africa, etc.) are not readily available, the total number of scientists and engineers who left the German-speaking world in the years immediately after the war was likely well over 10,000, or the majority of the creators who were still in the German-speaking world in 1945.[4]

---

[4] For more information on the transfer of German-speaking scientists, see Albrecht et al. 1992; Bar-Zohar 1967; Bower 1987; Buyer and Jensen 1948; Byrd 1948; Crim 2018; DOW 1945b, 1946; Gimbel 1986, 1990a, 1990b, 1990c; Goudsmit 1947; Glatt 1994; Hall 2019a; Linda Hunt 1985; Morton Hunt 1949; Jacobsen 2014; Jensen 1948; Jösten 1947; Matthias Judt and Ciesla 1996; Kurowski 1982; Lasby 1971; Nagan 1947; O'Reagan 2014, 2019; Simpson 1988.

Postwar transferred equipment

Despite heavy bombing by Allied forces, a large majority of scientific, engineering, and industrial infrastructure and equipment from the German-speaking world survived the war, due to numerous vast underground installations, camouflage, target dispersal, and continuous rebuilding, as shown for example by the following reports:

The Hydra [*Newsweek* 1945-07-09 p. 52]:

> This job of controlling Germany . . . is no short-term business. The Germans are capable and industrious people. They are fired by their desire for revenge and can rebuild an industrial war machine and reorganize it for war purposes in a few short years, regardless of the damage wrought by bombing.
>
> That was how Leo T. Crowley, Foreign Economic Administrator, described the problem of controlling the Reich last week in testimony before a subcommittee of the Senate Military Affairs Committee. "If we were to leave Germany to its own devices and not to institute a program of economic and industrial disarmament, Germany could be far better prepared for war in five years than she was in 1939," Crowley said.
>
> Crowley cited these examples of Germany's capacity to rearm unless severely supervised:
>
> "Allied bombing and military operations accomplished their mission . . . But such military operations, basically selective in their character, were not and could not be executed so as to eliminate permanently a national industrial war potential."
>
> "As it stands today, Germany, except for the United States, is the outstanding armament machine shop in the world."
>
> "[Germany] has one dye plant that can turn out almost as much dye in one year as all the plants in the United States together" . . .
>
> "Practically all of the great iron and steel furnaces of Germany are ready for operation or can be in operation with minor repairs."
>
> "Germany was producing about 1,000,000 metric tons [of nitrogen] in 1939 . . . A large part of the capacity remains or can be rebuilt in a short time."
>
> "Germany did not lack materials for textiles . . . It would appear that little permanent damage has been done to most of the plants."
>
> "According to the best available estimates, the German synthetic-rubber capacity today is more than 100,000 tons."
>
> "In 1944, Germany was producing about 1,000,000 tons of natural petroleum and about 5,500,000 tons of synthetic oil . . . It is believed that a large part of Germany's 1944 capacity for producing petroleum products can be restored within a brief period."

German Industry Grew under Raids: Many Fields Showed Increase in Production During Last Year of War [NYT 1945-08-08 p. 15]:

> Captured records disclosing that the Germans had been able to rebuild plants and expand war production in the face of intensified bombings during the final year of the European war were made public here today to support a Congressional investigating committee's warning that Germany, even in defeat, remained a major threat to world peace. [...]
>
> The records, cited in detail in an official report of the Ministry for Armaments and War Production that were seized last spring, showed that in 1944 three times as many armored fighting vehicles, more than three times as many fighter-bombers and eight times as many night fighters had been produced [as] in 1942.
>
> In a number of war items there was an increase in the last quarter of the year. While there was a decreased production in some fields, increase of air-raid damage and loss of territory, the Ministry reported, it was "still possible to keep the armament industry continuously supplied with the necessary material, a task that could be fulfilled only by drastic measures of control. [...]
>
> "Additional power plants were made available in 1944. [...]
>
> "At the beginning of 1944 the supply of parts and components was the bottleneck of all forms of German armament production. By the autumn of 1944, sufficient reserves of material had been accumulated, with the result that, in spite of more difficult conditions in the basic industry, and also among subcontractors, the output of armaments could be maintained and in some cases even increased."

75% of Industries in Reich Survived [NYT 1945-10-11 p. 6]:

> Despite the almost incessant heavy bombing and the fierce battles fought on German soil, some 75 per cent of Germany's industry is intact or in a reparable condition, Col. James Boyd, chief of the industry division of the Office of Military Government, said today. [...]
>
> He did say, however, that in his opinion roughly 50 per cent of Germany's steel-producing machinery would have to be removed as reparations or destroyed.

Out of that surviving infrastructure, many hundreds (perhaps well over a thousand) of complete factories and laboratories were removed, as may be seen by more examples from contemporary news articles:

Soviet Said to Get Its Yalta Demand: Moscow's Share Believed Half of Movable Reich Property in Potsdam Reparations [NYT 1945-08-05 p. 6]:

> The Potsdam reparations agreement in effect gives the Russians about 50 per cent of the movable German property covered by the accord, officials familiar with the preliminary negotiations on the subject said today.
>
> [...A]bout 45 per cent of German assets of the capital variety covered by the agreement were situated in the Russian zone [East Germany].
>
> This high percentage surprised some persons familiar with pre-war German economy, who were under the impression that the bulk of German industrial installations were in the west, but it was pointed out that during and just before the war the Germans built up their industrial plant in the east, where they located some of the nation's largest and most efficient units.
>
> Added to the 45 per cent of total movable German plant and equipment said to be situated in the Russian zone, the Soviet Government receives, under the agreement, 10 per cent of certain capital equipment in the western zones [West Germany]. [...]
>
> From the remainder of the movable equipment in the western zone, after the Russians get their 10 per cent, the reparations claims of all the United Nations in the war against Germany, except Russia, must be satisfied.

Allies Confiscate 300 Farben Plants: Part of Reich Trust's Factories to be Dismantled and Used to Pay Reparations: Other Assets Also Taken [NYT 1945-10-13 p. 3]:

> The Allies have confiscated the entire holdings in Germany of the octopus-like I. G. Farbenindustrie, without whose vast industrial output the Germans would have been unable to wage war. General Clay, administrator of civil affairs in American-occupied Germany, announced tonight that a part of the 300 plants owned by the huge trust would be dismantled and taken by the Allies as reparations. [...]
>
> General Clay estimated that about 75 per cent of Farbenindustrie's plants in Germany were intact. [...]
>
> Pre-war assets of the trust were estimated at 5,000,000,000 Reichsmarks—$2,000,000,000.
>
> Construction costs alone for the plants all over Germany and in Czechoslovakia amounted to $762,800,000, Colonel Pillsbury estimated.

Germans Report More Removals: Say 310 Plants in Thuringia Have Been Sent To Russia—Fear Wide Unemployment [NYT 1946-10-27 p. 32]:

> According to a report of the reparations department of the Thuringian Land Bureau for Economics, by the end of June, 1946, 310 plants in Thuringia alone had been fully dismantled by the Russians. The report added that during the third quarter of this year 410 Thuringian plants had worked exclusively on reparations deliveries of goods made from German raw materials[...] As of Oct. 1 the entire production quota of Thuringia has been allocated to Soviet occupation forces, the report added.
>
> Representatives of workers in glass factories and optical works in Jena, in their telegram Friday to the Allied Control Council, especially cited the stripping of that basic industry from the one-industry town[...]
>
> Accordingly the Russians apparently have made plans to drop their efforts to conciliate the Germans and instead drain all possible resources out of the country as quickly as possible.

BIOS 290, *The Viscose Continuous and Rayon Staple Fibre Plants of the British, American and French Occupation Zones of Germany*, pp. 2–3:

> The Team visited Germany with one primary object which was to assess the value of any suitable plant likely to be seized as Reparations, in accordance with the Potsdam Agreement.
>
> A very agreeable and secondary objective was the acquisition of any further technical knowledge, and an additional report has therefore been written to supplement the information gathered by the C.I.O.S. earlier in the year. [...]
>
> It will be appreciated that the report of the C.I.O.S. became a very useful charter and enabled us to investigate thoroughly the obviously new departures in the preparation, spinning and finishing of Viscose Yarn and Rayon Staple. It might be of general interest to say that the impression gathered by the team was that the Viscose industry of Germany has developed rapidly along mass production lines with a high degree of endeavour to eliminate handling and to shorten the Viscose preparation times as much as possible by the introduction of many new shredding and mixing devices. [...]
>
> In the Rayon Staple field the output of yarn per spinning position has reached almost fantastic proportions. 15,000 denier is now quite common with an individual filament denier of 1.5. We learned that some spinners are now contemplating an increase to 22,500 denier, using a jet of 15,000 holes of 0.07 m.m. diameter. Spinning pumps of the order of 75.0 ccs. per rev. are already in use. Rheinische Zellwolle use only 5 combination machines to produce 80 tons per day.
>
> We would specially draw attention to our recommendation on the Zellwolle Lehr Spinnerei Research Station at Denkendorf. It is the opinion of the team that this would be a valuable acquisition to the British Rayon Industry.

BIOS 428. *German Rayon and Staple Fibre Industry and Allied Engineering Industry.* p. 3:

> This work was undertaken following the original reconnaissance of the German Rayon and Staple Fibre Industry (Ref. 1) and had as its primary object the evacuation of a number of machines and processes upon which it was considered detailed investigation and development work should be carried out for the benefit of the British Viscose Rayon Industries. [gives long, detailed list of machines to be taken from Germany]

RARE METALS REFINING IN AXIS TERRITORY -- BERYLLIUM

1. Firms engaged: Siemens & Halske
Heraeus-Vacuumschmelze

Andrew Gahagan, of the Beryllium Corporation of Pennsylvania, stated at the TNEC hearing in 1939:

> Mr. Gahagan: Well, Siemens & Halske, as I found later when I went over there, is a tremendous company. They are interested in all sorts of businesses; their chief business is electrical equipment. They have their principal plant right outside of Berlin in a place called Siemenstadt, where they have some 150,000 employees alone in this Berlin plant. They have a research laboratory--I am sure it is considerably larger than all the Bureau of Standards, all the buildings out there. They spend large sums every year on research. They have ramifications of all kinds; they build electrical equipment; they build or are interested in chemistry and metallurgy. To describe how important Siemens is in Germany, I would say if you took du Pont and the Ford Motor Co. and General Electric all together, why that might relatively represent the importance of Siemens. They are one of the largest companies and the most successful of companies, and the best operating companies, in the entire world.
>
> (From Hearings before the Temporary National Economic Committee, Congress of the United States, Part 5, pages 2024-2025.)

2. Gahagan's further testimony indicates that Dr. Illig is head of the Research Department of Siemens. Heraeus Vacuumschmelze is headed up by Dr. Rohn, Gahagan said. It appears that Heraeus Vacuumschmelze was started by a Dr. Heraeus, who, Gahagan claims, went to the German Government and got funds with which to put up Heraeus Vacuumschmelze.

Figure 11.14: An example of the physical size and technological and financial importance of German industrial plants [NARA RG 77, Entry UD-22A, Box 169, Folder 32.32. Germ. Ind. TA].

All four major Allied countries claimed huge amounts of German and Austrian equipment. For example, Vincent Nouzille and Olivier Huwart wrote about some of the factories and other equipment that were acquired by France [Nouzille and Huwart 1999]:

Cette histoire débute au printemps de 1945, alors que les armées alliées resserrent leur étau sur le IIIe Reich. Les troupes de la Ire armée française du général de Lattre avancent dans le sud de l'Allemagne. Parmi les unités de reconnaissance qui les précèdent se trouvent des membres de la "section T". Ces experts du renseignement technique sont chargés de repérer les installations militaires et scientifiques allemandes. Si possible avant les autres vainqueurs. Par chance, le sud de l'Allemagne est truffé de dizaines d'usines et de laboratoires, repliés dans cette région moins exposée aux bombardements alliés.	This story began in the spring of 1945, when the Allied armies tightened their grip on the Third Reich. General de Lattre's troops of the First French Army advanced into southern Germany. Among the reconnaissance units preceding them were members of "Section T." These technical intelligence experts were responsible for identifying German military and scientific installations. If possible before the other winners. Fortunately, southern Germany was full of dozens of factories and laboratories, folded back into this region less exposed to Allied bombardments.
La chasse au butin est ouverte. Une équipe du 2e bureau de l'armée de l'air découvre ainsi près d'Oberammergau une vingtaine de caisses plombées, contenant 2 500 documents ultrasecrets du bureau d'études de l'avionneur Messerschmitt. Des trésors inestimables, ramenés à Paris pour être exploités par les industriels. Les formes d'ailes en flèche des futurs chasseurs français Ouragan et Mystère sont inspirées de ces documents.	The hunt for loot was on. A team from the 2nd office of the French Air Force discovered around twenty sealed boxes near Oberammergau, containing 2,500 top secret documents from the design office of the aircraft manufacturer Messerschmitt. Priceless treasures, brought back to Paris to be exploited by industrialists. The arrow-shaped wings of the future French fighters Ouragan and Mystère were inspired by these documents.
Près de 50 000 tonnes de matériels divers sont également envoyées en France durant l'année 1945. Des centaines d'équipements des usines aéronautiques de Dornier et Zeppelin à Friedrichshafen franchissent la frontière. La soufflerie subsonique d'Ötztal, dans le Tyrol autrichien, est démontée avant d'être réinstallée à Modane-Avrieux sous les auspices de l'Onera (Office national d'études et de recherches aéronautiques).	Nearly 50,000 tons of various materials were also sent to France in 1945. Hundreds of pieces of equipment from the Dornier and Zeppelin aeronautical plants in Friedrichshafen were taken across the border. The Ötztal subsonic wind tunnel in Austrian Tyrol was dismantled before being relocated to Modane-Avrieux under the auspices of Onera (Office national d'études et de recherches aéronautiques) [where it is still in use].

Près de 200 usines “civiles” allemandes—comme le complexe chimique BASF d’IG Farben à Ludwigshafen—sont remises en marche par les Français dans la zone d’occupation qui leur est octroyée par les accords de Potsdam de juillet 1945. Cette zone couvre 10% de l’Allemagne et une partie de l’Autriche. Les installations à vocation militaire sont également rouvertes. Dans la région du lac de Constance, 17 usines et laboratoires travailleront, jusqu’à leur déménagement, en 1948, dans le sud de la France, avec du personnel allemand, pour le compte de la marine française. Le physicien Yves Rocard (père de Michel) supervise une partie de ces récupérations. “On s’en est donné à coeur joie, en ramassant des Allemands eux-mêmes”, raconte-t-il dans ses *Mémoires sans concessions* (Grasset, 1988). D’autres scientifiques français viennent évaluer le potentiel scientifique nazi. Le chimiste Henri Moureu, qui a étudié de près les V 2 tombés près de Paris, réussit à visiter en juin 1945 l’usine Mittelwerke-Dora où étaient notamment fabriqués ces engins. Son ami physicien Frédéric Joliot-Curie, directeur du nouveau CNRS, dépêche, quant à lui, plus de 400 missions en Allemagne. Des expéditions parfois risquées: on retrouvera un jour à Vienne le cadavre d’un scientifique français, probablement jugé trop curieux par les Soviétiques...	Nearly 200 German “civilian” factories—such as the BASF chemical complex of IG Farben in Ludwigshafen—were restarted by the French in the zone of occupation granted to them by the Potsdam agreements of July 1945. This area covered 10% of Germany and part of Austria. Military facilities were also being reopened. In the Lake Constance region, 17 factories and laboratories worked with German personnel on behalf of the French navy until they moved to southern France in 1948. The physicist Yves Rocard (Michel’s father) supervised some of these recoveries. “We had a great time, picking up Germans themselves,” he says in his *Mémoires sans concessions* (Grasset, 1988). Other French scientists came to evaluate the Nazi scientific potential. The chemist Henri Moureu, who had closely studied the V-2s that had fallen near Paris, succeeded in visiting the Mittelwerke-Dora factory in June 1945, where these machines were manufactured. His physicist friend Frédéric Joliot-Curie, director of the new CNRS, sent more than 400 missions to Germany. Sometimes risky expeditions: one day in Vienna we found the body of a French scientist, probably considered too curious by the Soviets...

In addition to whole factories and laboratories, untold amounts of supplies, equipment, and prototypes were appropriated by Allied countries after World War II. A 1945 U.S. Navy document [NARA RG 38, Entry 72] listed examples of equipment transported to the United States in one shipment, including a submarine, 39 aircraft, V-1 and V-2 missiles, and other advanced technology prototypes.

Some newspaper headlines illustrate other examples:

> U.S. Navy to Use German Weapons [NYT 1945-06-30 p. 3].
>
> Use of Armament Seized in Europe Asked in Pacific [NYT 1945-07-07 pp. 1, 3].
>
> Ten U-Boats for Russia to be Yielded in Ulster [NYT 1945-11-22 p. 16].

>
> All German Scrap Is Now Allocated [NYT 1948-09-04 p. 19].

As may be seen from these and other newspaper articles, large-scale removals were still going on over 3½ years after German surrender. So many industrial plants and their supplies and equipment were removed, and for so many years, that Germans began to protest that the continuing removals would hinder their ability to peacefully rebuild and support themselves financially. As reported in these articles, western Allied countries responded by threatening to cut off Germany's food supply if any further protests were made:

> Germans Strike Against Removals [NYT 1946-10-29 p. 10].

The Soviet occupation and exploitation of areas they controlled was much more brutal and lasted until 1990.[5]

Soviet exploitation of German industry was also far larger than the number of German plants would seem to indicate. The Soviet Union apparently had a systematic policy of shipping half of a German plant and its workforce to the Soviet Union, forcing the remaining German workers to rebuild and restaff the plant until it was functional again, then shipping half of the rebuilt plant and workers to the Soviet Union, and repeating the process many more times. Thus the number of industrial plants that the Soviet Union extracted from Germany was many times the number of original plants. Even in its divided and war-ravaged state, Germany was mass-producing modern industrial plants for the entire Soviet Union, covering everything from aerospace to electronics to chemical technologies.

This Soviet practice was documented for example in the following U.S. intelligence report: Headquarters Berlin Command, Office of Military Goverment for Germany (US). 11 December 1946. Special Intelligence Memorandum No. 48. Subject: V-2 Production in SovZone. Source: Extremely Reliable. D-138175. [NARA RG 319, Entry A1-134A, Box 29, Folder ZA 019293 Soviet Guided Missiles, Rockets and V-Weapons Research, Development and Production Vol. 1, Fldr. 2 of 3. See pp. 2960–2961.]:

> BLEICHERODE in the Harz mountains is still doing fine in the production of V-2 rockets. It was reported from this office that dismantling was going on, but it was stopped as of 1 December. The general procedure for dismantling of installations very dear to the Soviet heart is the following as illustrated best by BLEICHERODE.
>
> As soon as Soviet troops took over the V-2 plants, they did everything in their power to get it reorganized and re-equipped. As soon as this was done, they started production. When they saw that the finished product was satisfactory, they began to dismantle the plant for the first time. The dismantling was not carried through completely, but was halted as soon as about half was taken. Together with the machinery some personnel was taken out, to be shipped to the USSR in order to set up the machinery which was confiscated and complete it with more later.
>
> In the meantime the plant in BLEICHERODE was being rebuilt under supervision of German and Soviet engineers. Once rebuilt, production was started all over again and as soon as satisfactory results were achieved, the dismantling was continued. In this way, Soviet authorities enrich their own country by building up some priceless industries and on the other hand they see to it that the original plant in Germany is reconstructed and re-equipped after each time. Thus, they would be able theoretically to continue an uninterrupted flow of industries from Germany to the Soviet Union.
>
> This procedure is known to have been applied to all V-weapon plants in BLEICHERODE, NORDHAUSEN, GOTHA and BERLIN. In BLEICHERODE the installations were dismantled for the fourth time; in NORDHAUSEN for the sixth time; in Berlin only once; conditions in GOTHA are unknown. [...]

It is helpful to visualize the locations of scientific research, development, and production sites from which various countries removed plants, materials, prototypes, scientists, and information at the end of the war.

Figure 11.15 shows a map of areas controlled directly or indirectly by Germany in 1942. Although much of German research and industry was located within the Greater German Reich (darkest area), there were also major sites in satellite countries from Norway to Bulgaria. At the end of the war, Allied countries seized resources, personnel, and information from sites in the respective regions they regained or occupied.

Figure 11.16 presents a detailed map of the Greater German Reich in 1941, not including satellite countries that were also controlled by Germany. Note that the Greater German Reich covered the territory of not only modern Germany but also modern Austria, Poland, and the Czech Republic, as well as small portions of other countries. At the end of the war, the majority of this territory was occupied by the Soviet Union and therefore was generally not open to inspection by western Allied investigators.

As an example of the distribution of wartime sites that were ultimately seized by Allied countries, Fig. 11.17 shows a map of plants run by or affiliated with I.G. Farben in 1943. The large majority were located within the Greater German Reich (covering modern Germany, Austria, Poland, and the Czech Republic), although a few I.G. Farben plants were located outside that territory (mainly in France). There were also I.G. Farben-associated facilities in Norway that are not shown on this map.

Some (but certainly not all) major sites involved in scientific research, development, and production during World War II are shown in:

- Fig. 11.20 for locations in modern Germany.
- Fig. 11.21 for locations in modern Austria and Hungary.
- Fig. 11.22 for locations in modern Poland and Russia.
- Fig. 11.23 for locations in the modern Czech Republic and Slovakia.

Figure 11.20: Some major sites involved in research and development during World War II that are located in modern Germany.

Notes for Fig. 11.20, showing sites located in modern Germany:

Berlin area: universities and technical schools; Kaiser Wilhelm Institutes; Kummersdorf and Spandau army research centers; Oranienburg Auer/SS research center; Reichspost research institutes; AEG, Siemens, Degussa, I.G. Farben, and other industry (e.g., pp. 3608, 3694, 3927, 4180, 4182, 4980) [Hayes 2004; Nagel 2016].

Braunschweig: Luftfahrtforschungsanstalt; Göring Werke; SS facilities; Buchler uranium (p. 4980).

Bremerhaven: naval research and development (e.g., p. 1457).

Dresden: Reichspost, AEG, and other laboratories (pp. 4305, 4507).

Elberfeld/Leverkusen area: I.G. Farben plants, including chemical warfare (e.g., pp. 3934–3935).

Erfurt area: numerous underground facilities (pp. 3708–3709, 4436–4438, 4478–4571) and also uranium deposits [Hayes 2004; Nagel 2016; Zeman and Karlsch 2008].

Frankfurt area: universities, research institutes, and industry [Hayes 2004; Nagel 2016].

Freiburg-im-Breisgau area: nuclear and other sites (pp. 3512–3540, 3696).

Friedrichshafen and Unterraderach (pp. 3921–3922).

Göttingen University.

Hamburg area: universities, research institutes, and industry; chemical and nuclear weapons development in Lüneburger Heide/Munster-Lager/Raubkammer (e.g., pp. 3494–3516, 4176–4182, 4406).

Heidelberg: university and Kaiser Wilhelm Institutes.

Jena: Zeiss (e.g., pp. 1270–1274, 1279, 2078); others in surrounding area.

Johanngeorgenstadt and Schneeberg area: uranium mining and use for nuclear development (pp. 3433–3437, 3456–3416, 3708, 4922) [Zeman and Karlsch 2008] .

Kaufering/Landsberg: installation possibly involved in nuclear work (p. 3692).

Kiel: naval research and development; uranium centrifuges (e.g., pp. 3494–3516).

Lehesten/Saalfeld area: underground rocket/aircraft/nuclear facilities (pp. 3689, 3696).

Leuna/Halle: I.G. Farben (e.g., pp. 4042–4054).

Munich area: universities, research institutes, and industry; Tegernsee facility (p. 3696).

Nordhausen: underground factories for rockets, missiles, and aircraft (e.g., pp. 5289–5294).

Peenemünde area of the Baltic coast: Peenemünde test center for rockets, missiles, and aircraft (e.g., pp. 3696, 5277–5288); Friedrich Löffler Institute for infectious disease research on Riems island (e.g., p. 197); military testing facilities on Rügen island (e.g., pp. 4390–4435); military testing facilities on Bornholm island, Denmark (e.g., pp. 3786, 4579); Lübeck, Dräger Werke (e.g., p. 4062); other facilities to produce and test advanced weapons and aircraft.

Piesteritz: chemical and possible nuclear development work (p. 4452).

Sigmaringen (p. 3696).

Stassfurt vicinity: underground Salzbergwerke facility for rocket and nuclear development (p. 3697).

Tübingen: university and research facilities (p. 3696).

Zellendorf: SS nuclear facility (p. 3694).

Figure 11.22: Some major sites involved in research and development during World War II that are located in modern Poland and Russia.

Notes for Fig. 11.22, showing sites located in modern Poland and Russia:

Baltic coast/Pomerania: many military test ranges located along most of the coast (e.g., p. 4396, Leba/Rumbke, etc.).

Blizna: SS Truppenübungsplatz Heidelager A-4 (V-2) rocket test/launch site.

Bydgoszcz/Bromberg: underground facility, possibly nuclear-related (e.g., p. 4456).

Choszczno/Arnswalde: secret large underground factory (p. 5560).

Gdansk/Danzig: Anti-radar/anti-sonar; uranium enrichment (pp. 3560, 4406, 4521).

Kaliningrad/Königsberg, Russia: Henschel guided missile development (e.g., p. 3928).

Lubań/Lauban area:

- GEMA-Werke for electronics.
- Leśna/Marklissa: VDM factory for A-4 (V-2) rocket engines.
- Zgorzelec/Görlitz: underground factory for A-4 (V-2) rockets.

Nord test range: Henschel Hs 117 Schmetterling surface-to-air missile development.

Oświęcim/Auschwitz: large I.G. Farben production facility, heavy water production, and possibly other nuclear-related work (e.g., pp. 4443–4477); to the north, Auergesellschaft uranium facility at Katowice/Kattowitz and Messerschmitt Me 163 rocket plane development at Mierzęcice/Udetfeld.

Poznan/Posen:

- Nesselstedt/Reichsinstitut für Krebsforschung biological weapons research (pp. 2562–2575).
- Biological weapons production (e.g., p. 2582).
- Electromagnetic railgun production (e.g., pp. 3245–3246)
- Numerous factories to produce other advanced weapons and aircraft.

Racibórz/Ratibor: Siemens Plania Werke, graphite production for nuclear experiments.

"Riese" area of Lower Silesia (e.g., pp. 4504–4519):

- Ksiaż castle/Schloss Fürstenstein: Jägerstab/SS development.
- Numerous underground facilities, some of which were conducting nuclear work.
- Kowary/Schmiedeberg uranium mine (e.g., p. 3328) and heavy water production plant [Witkowski 2013, p. 224].

Szczecin/Stettin area.

- Mosty/Speck: underground facility, apparently nuclear work [Witkowski 2013, p. 224].
- Stargard and Miedwie Lake/Madüsee: surface-to-air missile development.

Tuchola Forest/Tucheler Heide: military/SS rocket testing and nuclear work (e.g., pp. 4462, 4902–4903) [Dornberger 1958, pp. 227–229].

Wrocław/Breslau area: uranium centrifuges (p. 4522); heavy water (pp. 4070–4071); Rheinmetall missiles; Brzeg Dolny/Dyhernfurth chemical weapons.

Figure 11.23: Some major sites involved in research and development during World War II that are located in the modern Czech Republic and Slovakia.

Notes for Fig. 11.23, showing sites located in the modern Czech Republic and Slovakia:

Brno/Brünn: Waffenwerke-Brünn, SS academy research institute (pp. 3694, 3997).

České Budějovice/Budweis: several Siemens electronics factories for guidance systems, proximity fuses, etc. (pp. 3979–4022, 5503–5566).

Děčín/Tetschen area (pp. 3979–4022, 5503–5566):

- Podmokly/Bodenbach Krizik Works/Weserwerke underground factory.
- Benesov nad Ploucnici/Beneschau AEG electronics factory.
- Schmidding factory for rockets and missiles.
- Neumann und Slabenow factories for metals and electronics.

Dubnica/Dubnitz, Slovakia: Skoda underground facility (p. 3784).

Jáchymov/St. Joachimsthal: uranium mine (pp. 3998, 4980–4984).

Liberec/Reichenberg and Jablonec/Gablonz area (pp. 3979–4022, 5503–5566):

- Bedrichov/Friedrichsthal/Benesov nad Ploucnici AEG factory for V-3 and V-4 rockets/guidance systems.
- Rychnov/Reichenau GETEWENT (Gesellschaft für Technisch-Wirtschaftliche Entwicklung mbH) SS electronics factory.
- Straz nad Nisou/Habendorf Skoda underground factory (p. 5549).
- Tanvald/Tannwald: multiple electronics and semiconductor research facilities (p. 2757).
- Turnov/Turnau aerospace research facility.

Litoměřice/Leitmeritz: Richard I–IV underground factories (p. 3689).

Opava/Tropau: I.G. Farben production plant, apparently involved in nuclear work (p. 3748).

Ostrava/Ostrau and Vitkovice/Witkowitz: I.G. Farben and other industrial production plants, apparently some of which were involved in nuclear work (pp. 3748, 3979–4022).

Plzeň/Pilsen: Skoda/SS research facilities and administrative headquarters (p. 4974).

Prague/Praha/Prag area (pp. 2757, 3137–3156, 3979–4022, 5503–5566):

- Charles University/Prague German University.
- Bohemian/Czech Technical University in Prague.
- Kbely/Gbel airfield.
- Čelakovice/Tschelakowitz cyclotron factory (northeast of Prague).

Příbram/Przibram/Pibrans: Skoda/SS rocket development facility (pp. 3751–3754, 4921, 5696).

Štěchovice/Stechowitz area: Blaumeise underground facilities, apparently nuclear (pp. 3755–3782).

Most of this section demonstrates the size of the industries controlled by Germany by giving examples of the numbers and types of plants built by Germany, the geographical distribution of plants, and the magnitude of the postwar transfer of plants, products, materials, scientists, documents, and other information to Allied countries.

One can also demonstrate the size of the industries controlled by Germany (and subsequently transferred) by two other measures:

1. Gross domestic product (GDP). Table 11.6 summarizes information from economist Mark Harrison [Harrison 1998, pp. 3–13] regarding the economic output of Germany and countries aiding Germany during the war. Prewar (1938) GDP figures are expressed in billions of 1990 U.S. dollars. The 1938 GDP numbers were 351.4 for Germany alone, 1046.5 for Germany plus other Axis/occupied countries, and 1166.7 for Germany plus other Axis/occupied countries plus nominally "neutral" countries that actually gave considerable material support to Germany. Although the only easily available figures are those 1938 numbers, the totals for German-controlled Europe were probably fairly comparable during the war. (Allied bombing and territorial losses toward the end of the war would tend to reduce the totals, whereas German-initiated industrial construction, relocation to avoid Allied bombing, use of low-wage and forced labor, and other policies would tend to increase the totals.)

For comparison, the U.S. GDP (expressed in billions of 1990 U.S. dollars) was 800 in 1938, rising to 1094 in 1941 and reaching a wartime peak of 1499 in 1944. Thus the economic and industrial resources controlled by Germany were roughly comparable to and perhaps even greater than those of the United States (yet outmatched by the combined resources of the United States plus the complete British Commonwealth plus the Soviet Union).

2. Electrical power production. According to the U.S. Strategic Bombing Survey (USSBS), at the end of 1944 the Greater German Reich had a total known electrical production capacity of 22 GW, with at least 16 GW of that currently then in use despite territorial losses, extensive bombing, and ongoing repair work.[6] See pp. 2102–2104. BIOS 342 estimated a total of 23 GW for 1944 (pp. 2105–2106). Note that that total known production capacity of 22–23 GW does not include secretive or specialized power plants for classified or dedicated projects in the Greater German Reich that were either not known to USSBS and BIOS (especially in areas occupied by the Soviet Union after the war) or known but not publicly revealed by USSBS and BIOS. Note also that that 22–23 GW does not include the electrical production capacities of other countries that were occupied by Germany, allied with Germany, or nominally neutral but exporting aid to Germany. Detailed numbers on those extra production capacities are difficult to find, but a reasonable estimate is that adding secretive production within the Greater German Reich and production outside the Greater German Reich would approximately double that 22–23 GW to ∼44–46 GW of total electrical production capacity to aid the German war effort.

---

[6] United States Strategic Bombing Survey. 1947. *German Electric Utilities Industry Report.* pp. 1, 4, Exhibit C, Exhibit D. https://books.google.com/books?id=U9Q9TS-FtSgC

Country	**GDP**
Germany	351.4
Other Axis/occupied:	
Austria	24.2
Baltic states	12.9
Belgium	39.6
Bulgaria	10.5
Czechoslovakia	30.3
Denmark	20.9
Finland	12.7
France	185.6
Greece	19.3
Hungary	24.3
Italy	140.8
Netherlands	44.5
Norway	11.6
Poland	76.6
Romania	19.4
Yugoslavia	21.9
Subtotal:	695.1
“Neutrals” supporting Germany:	
Portugal	12.9
Spain	51.1
Sweden	29.8
Switzerland	26.4
Subtotal:	120.2
Total:	1166.7

Table 11.6: Gross domestic product (GDP) figures for Germany and countries that aided Germany during World War II (1938 GDPs, expressed in billions of 1990 U.S. dollars [Harrison 1998, pp. 3–13]. For comparison, the U.S. GDP (expressed in billions of 1990 U.S. dollars) was 800 in 1938.

For comparison, total production of electrical energy in the United States increased from 161,308 GW hr for the year of 1939, or a time-average of 18.4 GW electric power production, to 271,255 GW hr for 1945, or a time-average of 31.0 GW electric power production.[7] Thus the electrical power available to aid Germany was roughly comparable to and possibly even greater than the electrical power production of the United States (though outmatched by the combined electrical power of the United States plus the complete British Commonwealth plus the Soviet Union).

GERMAN ELECTRIC UTILITIES

PART I

GENERAL SUMMARY AND CONCLUSIONS

1. The objective of the Utilities Division was to examine the actual damage done by the bombing of Germany's electric generating plants and transmission networks, to study the effect of the resultant curtailment in suppply of electric energy upon Germany's war industry, and to reach conclusions concerning the desirability of electric utility systems as targets for strategic bombing.

2. German industry derived its electric supply from generating plants having a total nominal or name plate capacity at the end of 1944 of approximately 22,000,000 KW, or an available capacity of probably 16,000,000 KW. Of this nominal or name plate total, 13,300,000 KW formed the so-called "integrated system" (Verbundsnetz), which was under the jurisdiction of a National Load Dispatcher and consisted of all public utility systems and of the larger private industrial generating plants. The remaining 8,700,000 KW of the 22,000,000 KW nominal capacity, consisted of plants of industry, the national railroad system and isolated plants both large and small. The integrated system produced 45 billion kilowatt hours a year, of which probably over 80 per cent was consumed by industry. Of the 13,300,000 KW nominal capacity in the integrated system, 46 per cent was in hard coal burning plants, 33 per cent in brown coal burning plants, and 21 per cent in water power plants.

3. Generating stations were interconnected through substations by a high voltage transmission system which had as its backbone a 220 KV transmission line looping northward from the Swiss border through the Ruhr area, east to the vicinity of Leipzig, and then south to Austria. Radiating and interlacing with this system were a large number of 110 KV circuits partly for the collection of electric energy from off-lying generating stations, and partly for the delivery of electric energy to large industrial consumers and to municipal consuming areas. This transmission system, popularly spoken of as the "grid", was built according to plans originally made in 1926 primarily for the coordination of hydro power with thermal power with a view to economy.

4. Field surveys were made by the Utilities Division of the principal power plants in two great industrial areas of Germany: that around Leipzig where there is installed approximately one-fifth of all German public utility generating capacity; and that area from Essen to Cologne served by the large RWE (Rheinisch-Westfalisches Elektrizitatswerk A.G.) System, which comprises approximately 20 per cent of German capacity. The hydroelectric developments in southwest Germany which tie into and form an operating part of the RWE System were also inspected. Several electric substations and a generating station in northern Italy which had been bombed were also surveyed.

GERMAN ELECTRIC UTILITIES

PART II

BRIEF REVIEW OF THE ELECTRIC UTILITY INDUSTRY IN GERMANY

GENERAL.

1. Prewar Germany (including Austria and Sudeten territory) with a population according to 1939 census of 79,400,000 people and occupying an area of about 225,000 square miles, was largely industrial.

2. The principal industrial centers were:

The Ruhr and Saarland, for iron or steel production.
Berlin, for general manufacturing.
Bavaria and Prussia, for chemical manufacturing.
Saxony, for textile manufacturing.

The main centers of power generation were:

Rhine-Westphalia brown coal and hard coal areas.
Southwestern German water power area (including Austria.)
Central German brown coal area (including Leipzig and Berlin.)
Silesian hard coal area.

3. From data obtained from the office of the National Load Dispatcher the total generating station capacity, both public utility and private plant, in 1944 was 22 million KW. From the German diagram of principal interconnecting transmission lines, dated 15 February 1945, Exhibit D, it appears that the distribution of the more important generating stations both public and private of 50,000 KW capacity and over was as follows:

Plant Size KW (x 1000)	Hard Coal	Brown Coal	Hydro	Thermal Hydro	Total
Over 200	1	4	0	0	5
100 to 200	22	12	6	0	40
50 to 100	24	9	14	3	50
Total	47	25	20	3	95

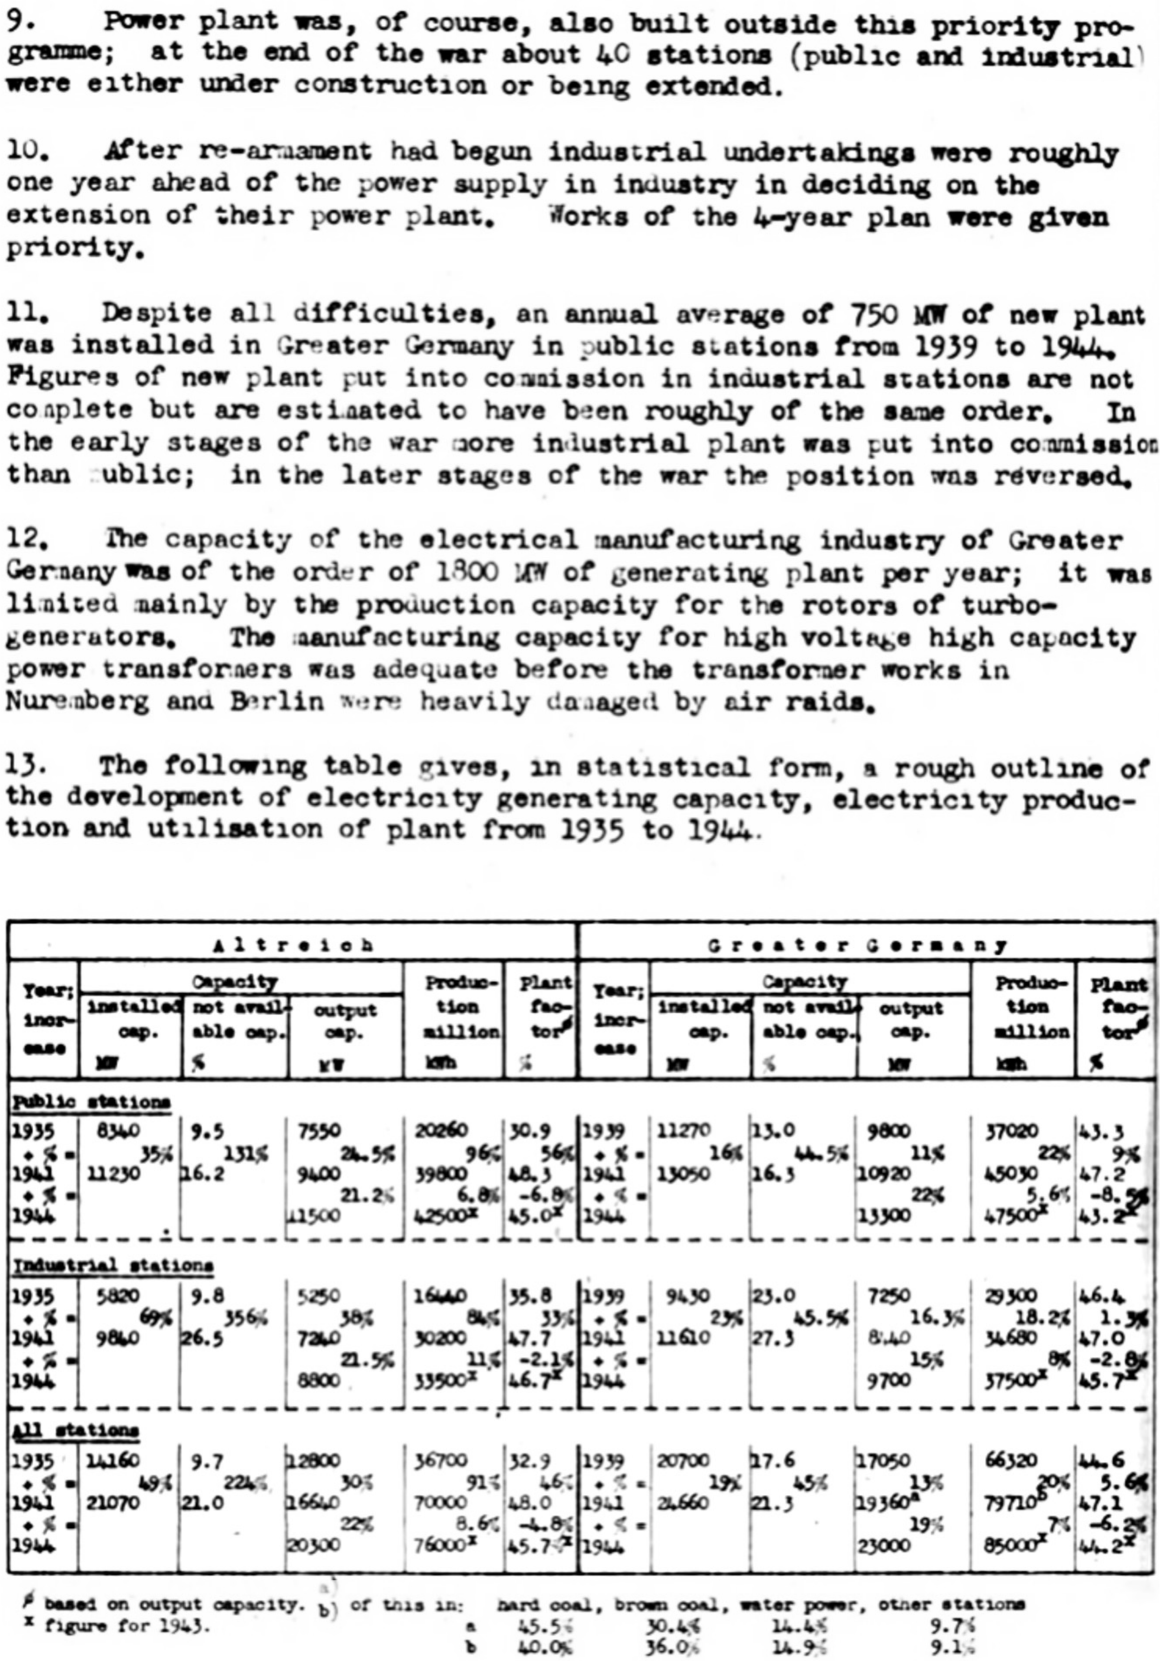
BIOS 342. *The German Wartime Electricity Supply: Conditions, Development, Trends.*



9. Power plant was, of course, also built outside this priority programme; at the end of the war about 40 stations (public and industrial) were either under construction or being extended.

10. After re-armament had begun industrial undertakings were roughly one year ahead of the power supply in industry in deciding on the extension of their power plant. Works of the 4-year plan were given priority.

11. Despite all difficulties, an annual average of 750 MW of new plant was installed in Greater Germany in public stations from 1939 to 1944. Figures of new plant put into commission in industrial stations are not complete but are estimated to have been roughly of the same order. In the early stages of the war more industrial plant was put into commission than public; in the later stages of the war the position was reversed.

12. The capacity of the electrical manufacturing industry of Greater Germany was of the order of 1800 MW of generating plant per year; it was limited mainly by the production capacity for the rotors of turbo-generators. The manufacturing capacity for high voltage high capacity power transformers was adequate before the transformer works in Nuremberg and Berlin were heavily damaged by air raids.

13. The following table gives, in statistical form, a rough outline of the development of electricity generating capacity, electricity production and utilisation of plant from 1935 to 1944.

Altreich						Greater Germany					
Year; increase	Capacity			Production million kWh	Plant factor ø %	Year; increase	Capacity			Production million kWh	Plant factor ø %

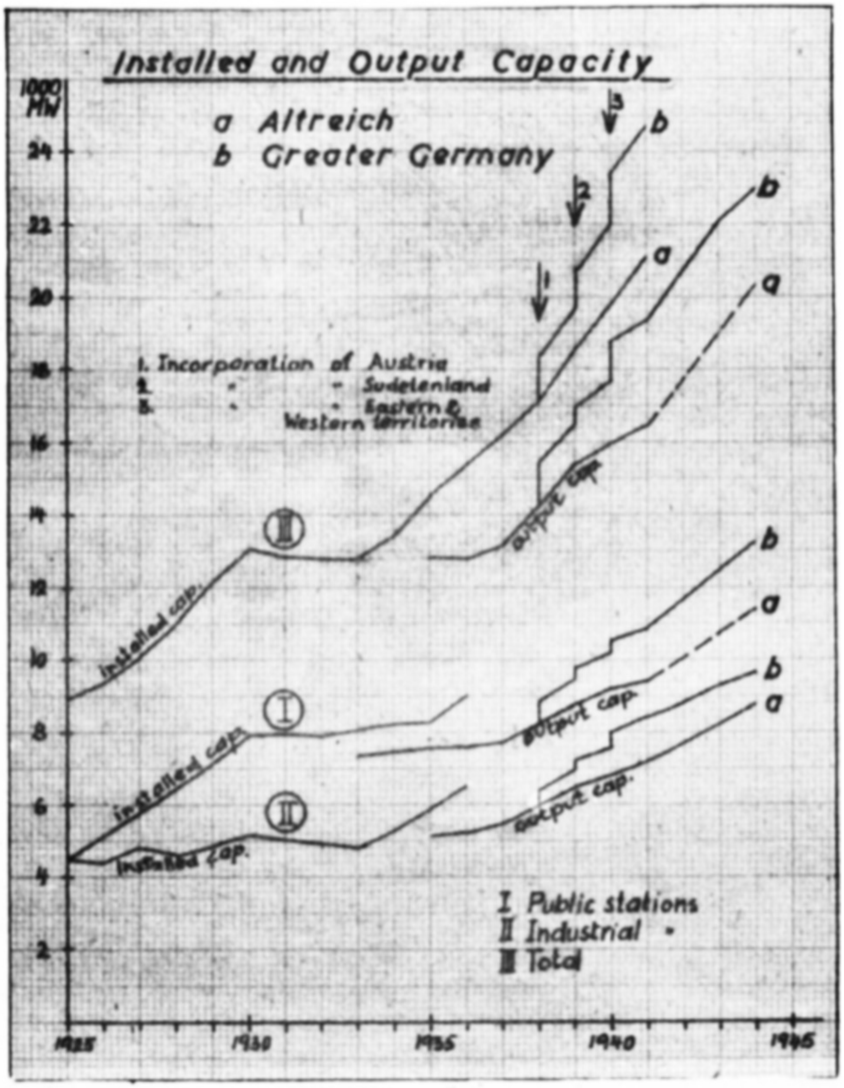
from the political side, on the supply undertakings, which were publicly accused of having over-invested in 1929 for their own benefit and of having thus misused public funds. This opinion was held even in the highest quarters and, when the quota system for steel was introduced in 1937, the electricity supply industry was at first refused an allocation. This refusal was, perhaps, the alarm signal for the supply undertakings, which now realised that their plant reserves had shrunk and that in the future it might not be at all easy, owing to the shortage of raw materials, to obtain the now necessary permission to build new plant.

Diagram 2



The electricity supply industry reacted quickly, but too late. As a result of numerous interventions and petitions a steel quota was allocated for power supply purposes in the autumn of 1937, but this was adequate neither to enable the supply industry to make good the plant shortage resulting from their own shortsightedness, nor to

Figure 11.28: BIOS 342. *The German Wartime Electricity Supply: Conditions, Development, Trends.*

Postwar transferred German-language documentation

In September 1945, R. P. Linstead and T. J. Betts, the British and American chairs of the Combined Intelligence Objectives Subcommittee (CIOS), bragged about the acquisition and processing of "thousands of bags" of German technical documents from up to 3377 targeted locations and scientists [AFHRA A5186 electronic version pp. 904–1026, Ch. 4, pp. 30, 32–33]:

> This file of CAFT Assessment Reports, giving details on 3,377 assessed targets is probably unique in the European Theatre. It is not a target list in the usual sense of the word, for it is not compiled from intelligence sources and therefore based on inferences regarding what should be found at the target. This file will doubtlessly serve as a primary source for target investigations in Germany for many months to come. [...]
>
> The Secretariat was responsible for the processing and despatch of thousands of bags of documents evacuated by CIOS investigators. It published accession lists giving the brief title of each document, thereby informing all concerned of the nature of documents temporarily available in the London area.

In fact, the United States transferred over 111,000 tons of German-language research documentation within just a three month period to one location (see p. 5258). Considering that the occupation and document removal process lasted several years, that documents were harvested by many different organizations and sent to many different locations, and that similar processes were carried out not just by the United States but also the United Kingdom, France, and Soviet Union, the total amount of transferred technical documents was almost certainly well over 111,000 tons—probably many multiples of that figure, likely over 1,000,000 tons of German technical documents.

The U.S. government then gave U.S. companies such as Bell Laboratories private access to captured German-language documentation [Gimbel 1990a, pp. 68, 71]:

> All of the letters asked for assistance in the recruitment of personnel whom OTS proposed to employ and send to Germany, but letters that went to private firms, such as the Bell Telephone Laboratories, also asked if the firms would be willing and able to send people to Washington for two or three months at company expense to analyze and index "an immense backlog of German technical documents" already on hand. Such "without compensation" (WOC) industrial representatives, who would obviously be in a position to benefit their employers directly, were promised "office space, secretarial and typing help, reproducing facilities, as well as the necessary access to all reports and documents"...
>
> Experts who volunteered would benefit by being the first to scrutinize the material. They could, in fact, use the original German materials for preparing professional articles that OTS would include in a "forthcoming Government Compendium of German wartime technology." Obviously—but apparently this was never stated explicitly—they could also apply what they found to their firms' research or use it in any other way that the firms and agencies that released them and paid them desired.*

> [...] As a matter of fact, the project was never completed and the proposed compendium never appeared, with the result that individuals and firms got private access to "intellectual reparations" that were originally intended for dissemination to the general public. [...]
>
> *For example, one of Bell Laboratories' people was spending half-time in Washington to go over technical literature gathered by OTS "and search for reports that might be of interest to the Laboratories."

For relevant documents, see p. 2967 and many other documents in Section B.5.

Similarly, after the war hundreds of thousands of patents from German-speaking inventors were transferred to the United States. The seizure of the patents by the United States was covered in a number of contemporary newspaper articles, such as the following examples:

To Keep German Patents: Alien Property Custodian Will Avert Return to Reich Owners [NYT 1945-06-06 p. 11]:

> James E. Markham, Alien Property Custodian, said today that every effort would be made to prevent German-controlled-corporations and patents, seized during the war, from returning to German hands.

German Patents To Aid U.S. Plants [NYT 1946-03-14 p. 44]:

> American industry will benefit substantially as a result of the quantities of patents and manufacturing information seized by the American technical group in the United States zone of occupation in Germany and the vast amount of information obtained by the first American technical expedition in the Russian zone, Robert B. MacMullin, chief investigator of the technical industrial intelligence branch of the Department of Commerce, said yesterday[...]
>
> More than 4,000 documents covering a multiplicity of processes and scientific data have been prepared for selection alike by the corporations and the small businessman, he said and two-thirds of those included the German data. The Department of Commerce ultimately, Mr. MacMullin continued, expects to offer 100,000 of such documents, disseminating information hitherto known only to enemy countries.
>
> These patents, Mr. MacMullin emphasized, will enable American manufacturers in many instances to replace their lines with enemy developments.

100,000 German Patents Available [NYT 1946-08-09 p. 8]:

> James E. Markham, Alien Property Custodian, said today that more than 100,000 German patents seized during the war will become available, royalty-free, to countries that signed the patent accord in London last week.

U.S. Said To Seize German Patents: Russian Says That Billions in Reparations Have Been Taken Since Occupation [NYT 1947-02-16 p. 3]:

> An article in [the Soviet paper] The New Times said today that the United States and Britain already had taken from Germany the richest war booty ever obtained by victorious powers. [...]
>
> The longest article of all asserted that the two countries already had extracted "many billions of dollars" worth of reparations from Germany in the form of patents, technical information and the services of scientists and technicians.
>
> Mr. Rubenstein, author of the article, said that although the United States and Britain had not set a total of the reparations due them from Germany, "removal of reparations by them in various forms has been carried on since the beginning of the occupation." [...]
>
> Mr. Rubenstein asserted that in obtaining German patents United States capitalists had "the active help" of United States occupational authorities and the Government in Washington.
>
> "Expert engineers and qualified German scientific workers" were described as appearing in German research institutions, laboratories and industrial plants, learning all the secrets, condensing them and filming them for transmission to the United States.
>
> The writer said that hundreds of United States technicians had been sent to Germany to learn the secrets of her industry and hundreds of German and Austrian scientists had been sent to the United States to do research work and eventually become citizens.

German Patents List: Applications Filed in War Years Available for Allied Countries [NYT 1950-07-02 p. E7]:

> The Office of Technical Services of the Department of Commerce issues a new "finding" guide to wartime German patent applications, which may now be used freely in Allied countries. The guide is a subject index to the 200,000 German applications filed in the Berlin Patent Office over the period 1940–1945.
>
> The Association for the Diffusion of Documentation, Paris, France, compiled the finding guide, now translated for American use. The association is offering, at $3 each, microfilm copies of complete patent applications. The fee not only covers the preparation of the reproduction but the task of locating the application on some one thousand microfilm reels on which the German applications were copied.
>
> Copies of the German patent application finding guide, entitled "Subject Outline of the Unpublished Applications for Patents Filed at the German Patent Office 1940–1945," are available on request from the Office of Technical Services, United States Department of Commerce, Washington.

While early newspaper articles mentioned 100,000–200,000 seized German patents, the actual total appears to have been over 750,000. A 21 April 1947 letter from the Technical Industrial Intelligence Division to R. P. Isaacs stated [NARA RG 40, Entry UD-75, Box 12, Folder Technical Inquiries - H -, Technical Industrial Intelligence Division to R. P. Isaacs, 21 April 1947]:

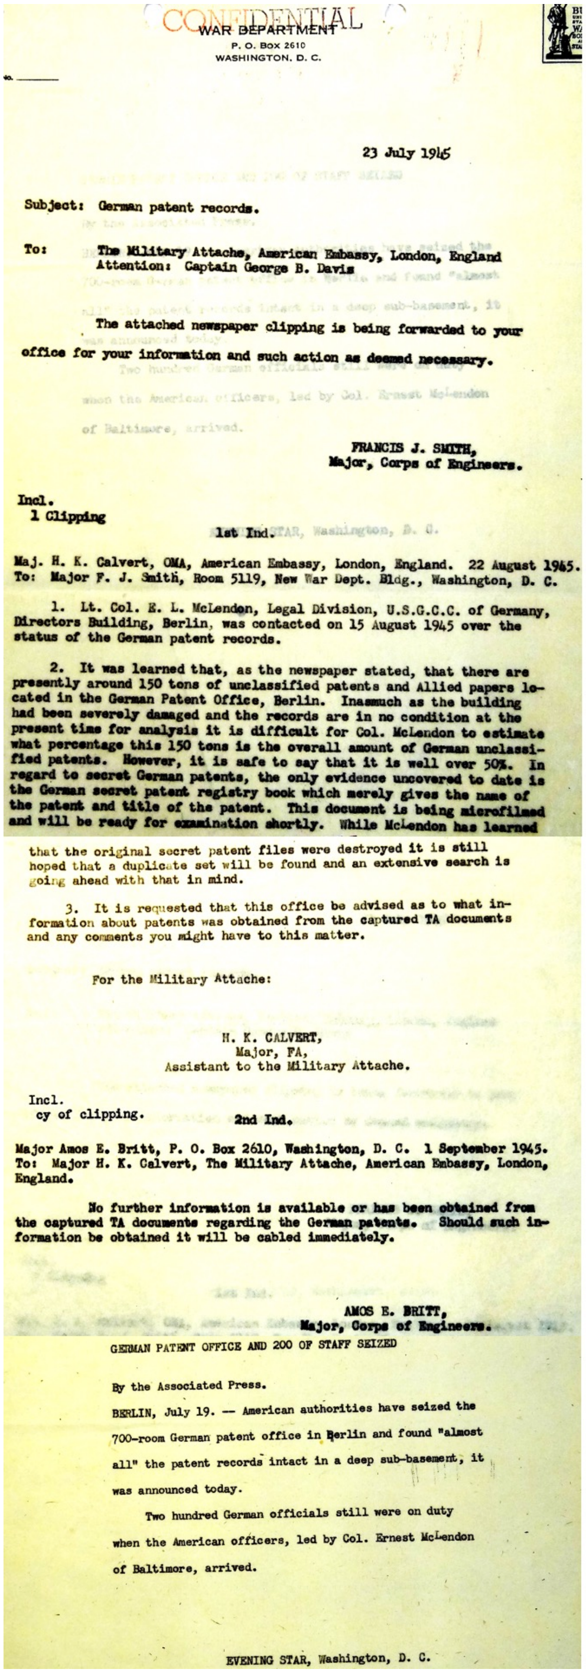
> You will probably be interested in knowing that single copies of almost all German patents issued during the war years up to V-E Day are on numerical file in the Patent Office Library in the Commerce Building. These files of German patents were seized at the Berlin Patent Office and evacuated to the United States in the spring of 1946. The German Patent No. 750986 is the latest one available. Photostatic copies of these patents may be ordered at 20 cents per page from the U.S. Patent Office, Washington 25, D.C.

See Figs. 11.30–11.31 for this complete document. If German Patent No. 750986 was the last known patent by the end of the war, the United States presumably would have possessed and asserted rights to German patents all the way back to the first one. See also the document in Fig. 11.50.

In fact, the total number of seized patents was likely even higher, since it would have included:

- Granted German patents up to at least number 750986.
- Granted Austrian patents.
- Patent applications filed but not granted in Germany by the end of the war.
- Patent applications filed but not granted in Austria by 1938.
- Secret classified German and Austrian patents.
- Patents and patent applications filed in other countries by German and Austrian inventors.

In addition to the United States, the Soviet Union seized huge numbers of German patents, and other countries may have as well.



~~CONFIDENTIAL~~

WAR DEPARTMENT
P. O. Box 2610
WASHINGTON, D. C.

No. ______

23 July 1945

Subject: German patent records.

To: The Military Attache, American Embassy, London, England
Attention: Captain George B. Davis

The attached newspaper clipping is being forwarded to your office for your information and such action as deemed necessary.

FRANCIS J. SMITH,
Major, Corps of Engineers.

Incl.
1 Clipping

1st Ind.

Maj. H. K. Calvert, OMA, American Embassy, London, England. 22 August 1945.
To: Major F. J. Smith, Room 5119, New War Dept. Bldg., Washington, D. C.

1. Lt. Col. E. L. McLendon, Legal Division, U.S.G.C.C. of Germany, Directors Building, Berlin, was contacted on 15 August 1945 over the status of the German patent records.

2. It was learned that, as the newspaper stated, that there are presently around 150 tons of unclassified patents and Allied papers located in the German Patent Office, Berlin. Inasmuch as the building had been severely damaged and the records are in no condition at the present time for analysis it is difficult for Col. McLendon to estimate what percentage this 150 tons is the overall amount of German unclassified patents. However, it is safe to say that it is well over 50%. In regard to secret German patents, the only evidence uncovered to date is the German secret patent registry book which merely gives the name of the patent and title of the patent. This document is being microfilmed and will be ready for examination shortly. While McLendon has learned that the original secret patent files were destroyed it is still hoped that a duplicate set will be found and an extensive search is going ahead with that in mind.

3. It is requested that this office be advised as to what information about patents was obtained from the captured TA documents and any comments you might have to this matter.

For the Military Attache:

H. K. CALVERT,
Major, FA,
Assistant to the Military Attache.

Incl.
cy of clipping.

2nd Ind.

Major Amos E. Britt, P. O. Box 2610, Washington, D. C. 1 September 1945.
To: Major H. K. Calvert, The Military Attache, American Embassy, London, England.

No further information is available or has been obtained from the captured TA documents regarding the German patents. Should such information be obtained it will be cabled immediately.

AMOS E. BRITT,
Major, Corps of Engineers.

GERMAN PATENT OFFICE AND 200 OF STAFF SEIZED

By the Associated Press.

BERLIN, July 19. — American authorities have seized the 700-room German patent office in Berlin and found "almost all" the patent records intact in a deep sub-basement, it was announced today.

Two hundred German officials still were on duty when the American officers, led by Col. Ernest McLendon of Baltimore, arrived.

EVENING STAR, Washington, D. C.

AMERICAN EMBASSY
OFFICE OF THE MILITARY ATTACHE
1, GROSVENOR SQUARE, W. 1.
LONDON, ENGLAND

30 October 1945

Subject: German Patents.

To: Major A. E. Britt, Room 5004, New War Dept. Bldg., Washington, D. C.

1. Reference is made to our letter of 28 September 1945 of same subject. A follow-up investigation of this subject by Lt. Warner in Berlin was made on 25 October 1945. Lt. Warner visited the German Patent Office and interviewed Lt. Col. Kessenick, U. S. Officer in charge of patent processing; Col. Monroe, British Officer in charge; and a British Officer by the name of Addison, who is assisting Monroe. A Major Billings, formerly with the personnel procurement section of OCE War Department, now with the Legal Section of US Group Control Council, and a patent lawyer by profession, was also interviewed for corroborative information.

2. All of the above named officers were agreed that all secret classified German patents were destroyed by the Germans in a city called Herringen near Kassel, Germany. Lt. Col. Kessenick inspected the charred remains of these documents and stated that they were incapable of being restored to legibility. Over 180,000 unclassified patent applications are now being processed and catalogued. Of those thus far catalogued no indication has been found that patents of interest to General Groves' office are among them.

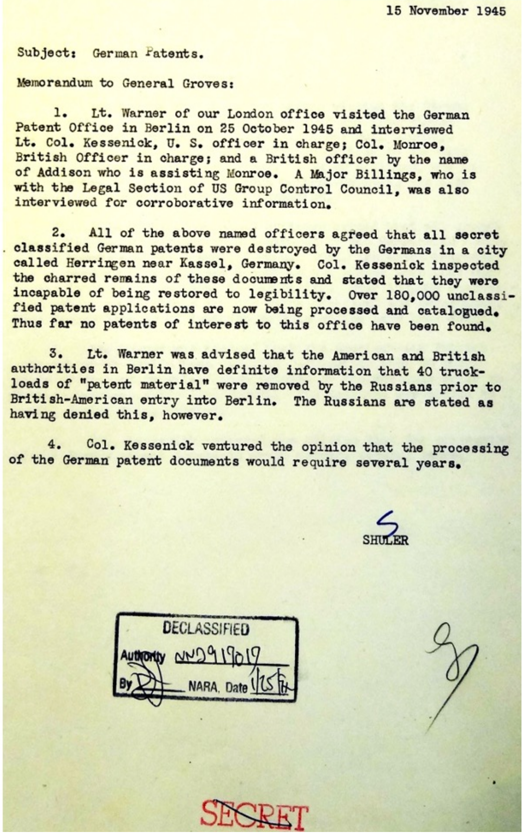
3. Lt. Warner was advised that the American and British authorities in Berlin have definite information that 40 truckloads of "patent material" were removed by the Russians prior to British-American entry into Berlin. The Russians are stated as having denied this, however.

4. Lt. Col. Kessenick ventured the opinion that the processing of the German patent documents would require several years.

For the Military Attache:

HK Calvert
H. K. CALVERT,
Lt. Col, CE,
Assistant to the Military Attache.

~~SECRET~~



15 November 1945

Subject: German Patents.

Memorandum to General Groves:

1. Lt. Warner of our London office visited the German Patent Office in Berlin on 25 October 1945 and interviewed Lt. Col. Kessenick, U. S. officer in charge; Col. Monroe, British Officer in charge; and a British officer by the name of Addison who is assisting Monroe. A Major Billings, who is with the Legal Section of US Group Control Council, was also interviewed for corroborative information.

2. All of the above named officers agreed that all secret classified German patents were destroyed by the Germans in a city called Herringen near Kassel, Germany. Col. Kessenick inspected the charred remains of these documents and stated that they were incapable of being restored to legibility. Over 180,000 unclassified patent applications are now being processed and catalogued. Thus far no patents of interest to this office have been found.

3. Lt. Warner was advised that the American and British authorities in Berlin have definite information that 40 truckloads of "patent material" were removed by the Russians prior to British-American entry into Berlin. The Russians are stated as having denied this, however.

4. Col. Kessenick ventured the opinion that the processing of the German patent documents would require several years.

Technical Industrial
Intelligence Division
Room 6829

21 April 1947

Mr. R. P. Isaacs
Hammill & Gillespie, Incorporated
225 Broadway
New York 7, New York

Dear Mr. Isaacs:

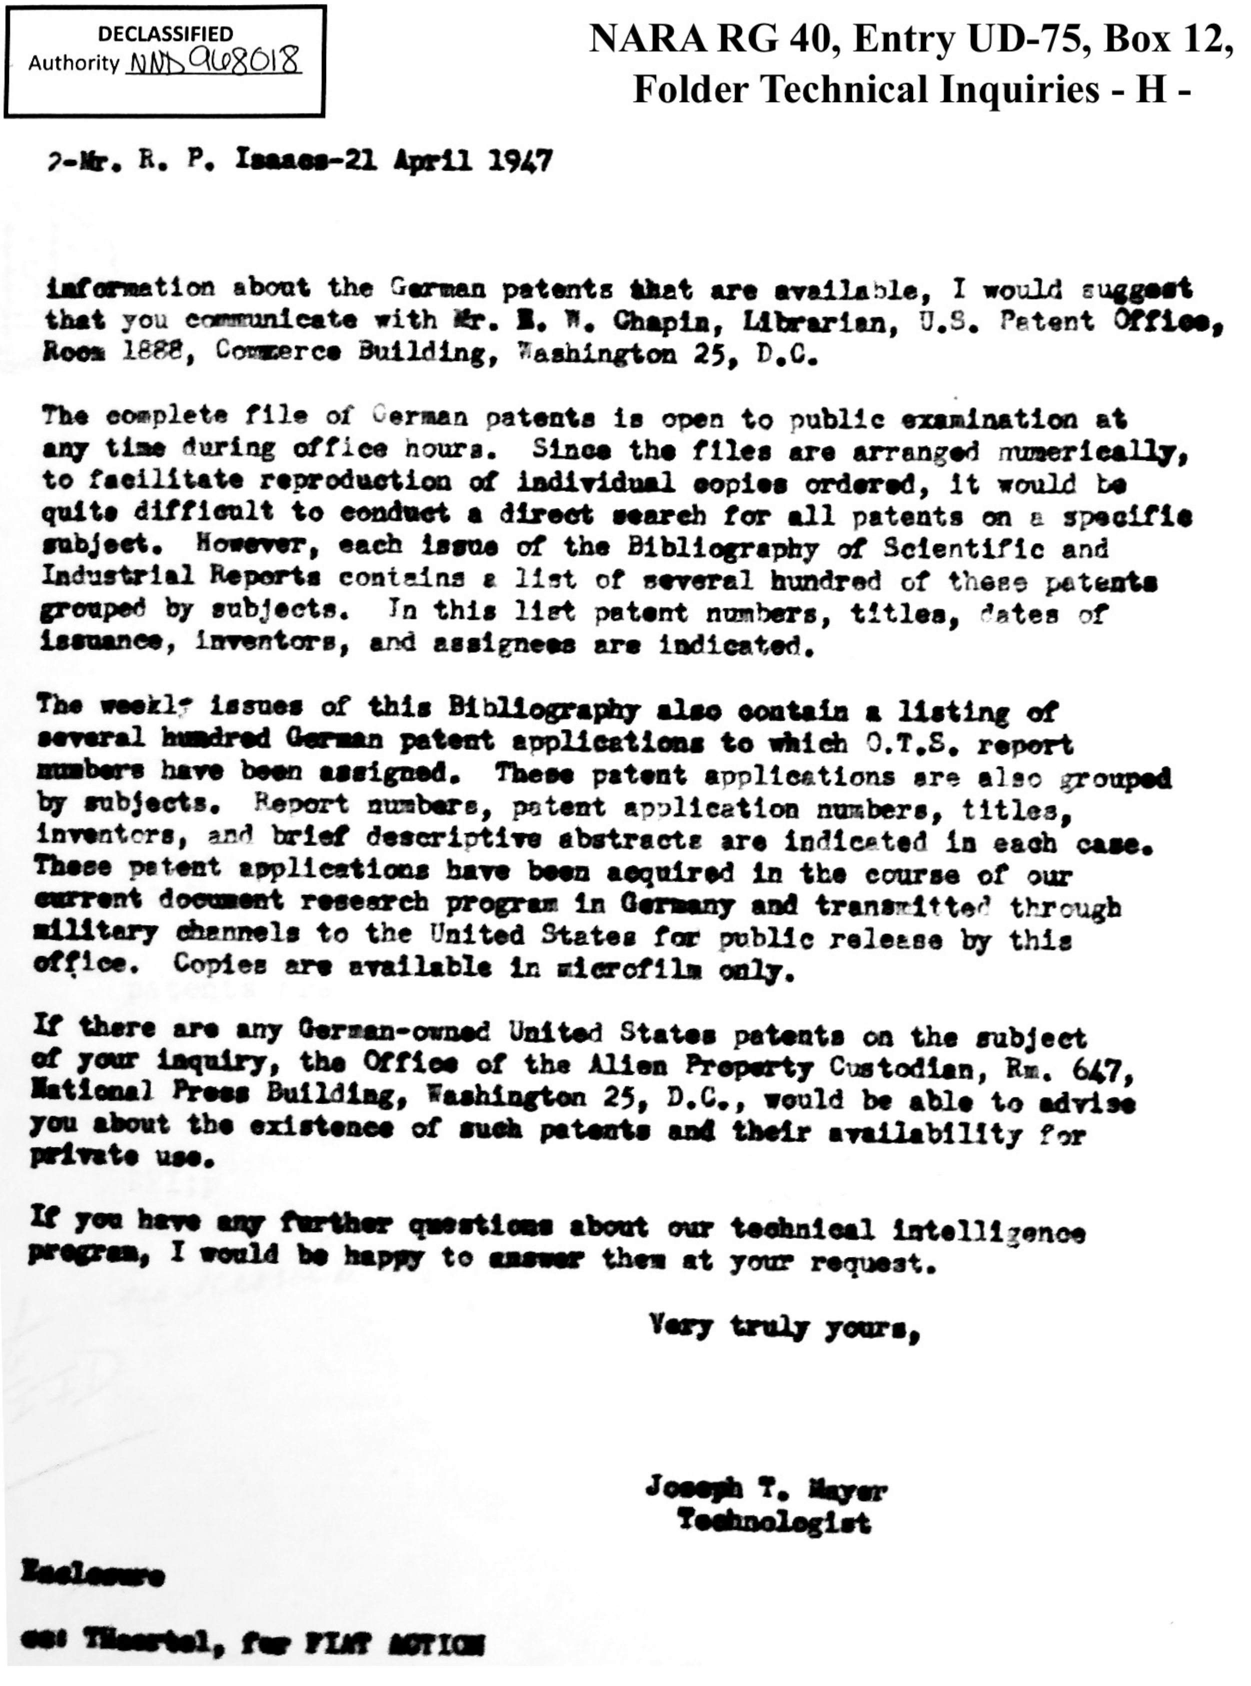
Your inquiry of 2 April 1947 for technical information on the manufacture of pumice bricks and pumice slabs by the Binstein Company in Germany has recently been referred to my attention.

Among the technical reports on file in this office we have been unable to find any references to the subjects of your inquiry. However, I have referred a copy of your letter to FIAT (Field Information Agency Technical), our agency at Karlsruhe, Germany, for further investigation. Any information on these subjects that can be located in the current files of FIAT or can be uncovered within the next few months in the course of our document research program in Germany, will be transmitted, through military channels, to this office for public release.

All technical reports and microfilmed documentary data thus acquired will be listed in our Bibliography of Scientific and Industrial Reports, which is described in the enclosed folder entitled, "Technical Facts for Industry". On the chance that you are not a subscriber to this Bibliography, I will be glad to keep you informed of our efforts to obtain the information that you have requested.

You will probably be interested in knowing that single copies of almost all German patents issued during the war years up to V-E Day are on numerical file in the Patent Office Library in the Commerce Building. These files of German patents were seized at the Berlin Patent Office and evacuated to the United States in the spring of 1946. The German Patent No. 750986 is the latest one available. Photostatic copies of these patents may be ordered at 20 cents per page from the U.S. Patent Office, Washington 25, D.C. Orders for copies should be accompanied by check or money order, made payable to the Treasurer of the United States. For further

Figure 11.30: After the war, more than 750,000 patents from German-speaking inventors were transferred to the United States [NARA RG 40, Entry UD-75, Box 12, Folder Technical Inquiries - H -, Technical Industrial Intelligence Division to R. P. Isaacs, 21 April 1947].



DECLASSIFIED
Authority NND968018

NARA RG 40, Entry UD-75, Box 12, Folder Technical Inquiries - H -

2-Mr. R. P. Isaacs-21 April 1947

information about the German patents that are available, I would suggest that you communicate with Mr. E. W. Chapin, Librarian, U.S. Patent Office, Room 1888, Commerce Building, Washington 25, D.C.

The complete file of German patents is open to public examination at any time during office hours. Since the files are arranged numerically, to facilitate reproduction of individual copies ordered, it would be quite difficult to conduct a direct search for all patents on a specific subject. However, each issue of the Bibliography of Scientific and Industrial Reports contains a list of several hundred of these patents grouped by subjects. In this list patent numbers, titles, dates of issuance, inventors, and assignees are indicated.

The weekly issues of this Bibliography also contain a listing of several hundred German patent applications to which O.T.S. report numbers have been assigned. These patent applications are also grouped by subjects. Report numbers, patent application numbers, titles, inventors, and brief descriptive abstracts are indicated in each case. These patent applications have been acquired in the course of our current document research program in Germany and transmitted through military channels to the United States for public release by this office. Copies are available in microfilm only.

If there are any German-owned United States patents on the subject of your inquiry, the Office of the Alien Property Custodian, Rm. 647, National Press Building, Washington 25, D.C., would be able to advise you about the existence of such patents and their availability for private use.

If you have any further questions about our technical intelligence program, I would be happy to answer them at your request.

Very truly yours,

Joseph T. Mayer
Technologist

Enclosure

cc: Thoertel, for FIAT ACTION

Figure 11.31: After the war, more than 750,000 patents from German-speaking inventors were transferred to the United States [NARA RG 40, Entry UD-75, Box 12, Folder Technical Inquiries - H -, Technical Industrial Intelligence Division to R. P. Isaacs, 21 April 1947].

A detailed 1946 news article provided a great deal of contemporary insight into how all of these German-language materials were used by the U.S. government and industry [Charles Walker 1946]:

> If you always thought of war secrets—as who hasn't?—as coming in sixes and sevens, as a few items of information readily handed on to the properly interested authorities, it may interest you to learn that the war secrets in this collection run into the thousands, that the mass of documents is mountainous, and that there was never before been anything quite comparable to it.
>
> The collection is today chiefly in three places: Wright Field (Ohio), the Library of Congress, and the Department of Commerce. Wright Field is working from a documents "mother lode" of fifteen hundred tons. In Washington, the Office of Technical Services (which has absorbed the Office of the Publication Board, the government agency originally set up to handle the collection) reports that tens of thousands of tons of material are involved. It is estimated that over a million separate items must be handled, and that they, very likely, contain practically all the scientific, industrial and military secrets of Nazi Germany.
>
> One Washington official has called it "the greatest single source of this type of material in the world, the first orderly exploitation of an entire country's brain-power." [...]
>
> The German Patent Office put some of its most secret patents down a sixteen-hundred-foot mine shaft at Heringen, then piled liquid oxygen, in cylinders, on top of them. When the American Joint Intelligence Objectives team found them, it was doubtful that they could be saved. They were legible, but in such bad shape that a trip to the surface would make them disintegrate. Photo equipment and a crew were therefore lowered into the shaft and a complete microfilm record made of the patents there. [...]
>
> For the war secrets, which conventionally used to be counted in scores, will run to three-quarters of a million separate documentary items (two-thirds of them on aeronautics) and will require several years and several hundreds of people to screen and prepare them for wide public use.
>
> Today translators and abstracters of the Office of Technical Services, successor to the OPB, are processing them at the rate of about a thousand a week. Indexing and cataloguing the part of the collection which will be permanently kept may require more than two millions cards; and at Wright Field the task is so complicated that electric punch-card machines are to be installed. A whole new glossary of German-English terms has had to be compiled—something like forty thousand words on new technical and scientific items.
>
> With so many documents, it has, of course, been impossible because of time and money limitations to reprint or reproduce more than a very few. To tell the public what is available, therefore, the OTS issues a bibliography weekly. This contains the newest war secrets information as released—with titles, prices of copies currently available or to be made up, and an abstract of contents.
>
> The original document, or the microfilm copy, is then generally sent to the Library of Congress, which is now the greatest depository. To make them more easily accessible to the public, the Library sends copies, when enough are available, to about 125 so-called "depository" libraries throughout the United States.

> And is the public doing anything with these one-time war secrets? It is—it is eating them up. As many as twenty thousand orders have been filled in a month, and the order rate is now a thousand items a day. Scientists and engineers declare that the information is "cutting years from the time we would devote to problems already scientifically investigated." And American business men...! A run through the Publication Board's letters file shows the following:
>
> The Bendix Company in South Bend, Indiana, writes for a German patent on the record player changer "with records stacked above the turntable." Pillsbury Mills wants to have what is available on German flour and bread production methods. Kendall Manufacturing Company ("Soapine") wants insect repellent compounds. Pioneer Hi-Bred Corn Company, Iowa, asks about "interrogation of research workers at the agricultural high school at Hohenheim." Pacific Mills requests I. G. Farbenindustrie's water-repellent, crease-resistant finish for spun rayon. The Polaroid Company would like something on "the status of exploitation of photography and optics in Germany." (There are, incidentally, ten to twenty thousand German patents yet to be screened.)
>
> The most insatiable customer is Amtorg, the Soviet Union's foreign trade organization. One of its representatives walked into the Publication Board office with the bibliography in hand and said, "I want copies of everything." The Russians sent one order in May for $5,594.00 worth—two thousand separate war secrets reports. In general, they buy every report issued. Americans, too, think there is extraordinarily good prospecting in the war secrets lode. Company executives practically park on the OTS's front doorstep, wanting to be first to get hold of a particular report on publication. Some information is so valuable that to get it a single day ahead of a competitor, may be worth thousands of dollars. But the OTS takes elaborate precautions to be sure that no report is ever available to anyone before general public release.
>
> After a certain American aircraft company had ordered a particular captured war document, it was queried as to whether the information therein had made it or saved it any money. The cost of the report had been a few dollars. The company answered: "Yes—at least a hundred thousand dollars."
>
> A research head of another business firm took notes for three hours in the OTS offices one day. "Thanks very much," he said, as he stood to go, "the notes from these documents are worth at least half a million dollars to my company."
>
> And after seeing the complete report on the German synthetic fiber industry, one American manufacturer remarked:
>
> *This report would be worth twenty million dollars to my company if it could have it exclusively.*
>
> Of course you, and anybody else, can now have it, and lots of other once secret information, for a few dollars. All the war secrets, as released, are completely in the public domain.

Konrad Adenauer, the first post-war Chancellor of West Germany, summarized the extent of the continuing damage to Germany in his memoirs [Adenauer 1966, pp. 147–148]:

> Let me mention the question of German patents in this context. You know that all German patents were released. At the end of 1948 the director of the American Office for Technical Services, Mr. John Green, gave the press a report on his activities, which were concerned with the exploitation of German patents and industrial secrets. What strikes one in this report is the fact that AMTORG was the keenest purchaser. That is Moscow's foreign trade organization. During one month alone the Russians bought more than two thousand Wehrmacht reports on secret German weapons for which they paid six thousand dollars. According to a statement made by an American expert the patents formerly belonging to IG Farben have given the American chemical industry a lead of at least ten years. The damage thus caused to the German economy is huge and cannot be assessed in figures. It is extraordinarily regrettable that the new German inventions cannot be protected either, because Germany is not a member of the Patent Union. Britain has declared that it will respect German inventions regardless of what the peace treaty may say. But America has refused to issue such a declaration. German inventors are therefore not in a position to exploit their own inventions. This puts a considerable brake on German economic development.

Figure 11.32 presents a photo of German and U.S. scientists sorting and translating "tons" of captured German and Austrian technical documents at Wright Field, Ohio, in 1946.

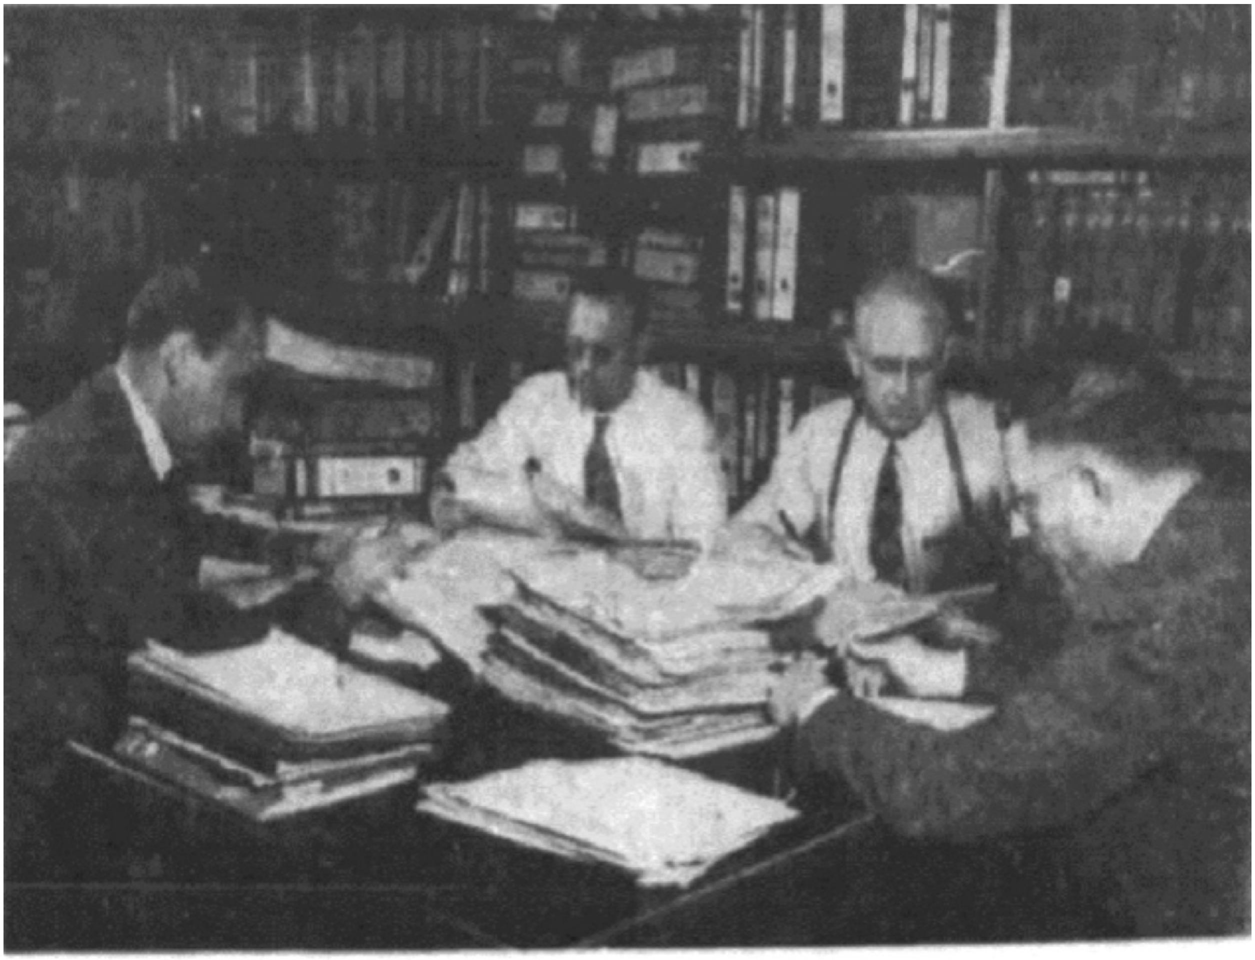
Figures 11.33–11.34 show further examples of rows and rows of bookcases filled with boxes of reports taken from and written about German and Austrian science and engineering programs, collected after World War II and stored at the U.K. Imperial War Museum in Duxford.

One key conduit for the transfer of published and unpublished scientific information out of the German-speaking world was Ján Ludvík Hoch (1923–1991), who was born in Czechoslovakia, moved to the U.K. during the war, and changed his name to Robert Maxwell, by which he ultimately became famous. Because Hoch/Maxwell was fluent in many languages, young, intelligent, and personally extremely ambitious, he found strong support in the British military and intelligence communities during and after the war. Biographer John Preston summarized his role in transferring scientific information [Preston 2021, pp. 20, 22, 25–27]:

> Maxwell's first job in Germany was at the Intelligence Corps headquarters at Iserlohn, 250 miles from Berlin. Along with the other British officers working there, he was given a pseudonym to protect his identity. For the next six months, he became 'Captain Stone', part of a team interrogating German prisoners and others who had worked for the Nazi regime. [...]
>
> Berlin had now been divided into four zones: the French, the British, the Russian and the American. Fluent in Russian, English, and French [as well as his native Czech and German], Maxwell could easily pass from zone to zone without attracting attention. As he'd proved before, he also had a natural bent for subterfuge. All this made him a highly prized asset as far as British Intelligence was concerned. [...]
>
> 'One of my secret jobs was to find out what the Russians were up to, stripping East German industries,' Maxwell told Goodman. [...]
>
> Maxwell also went on a number of undercover trips to Czechoslovakia, then teetering on the brink of a communist takeover—it would become part of the Eastern Bloc in February 1948. According to documents in the Secret Service archive in Prague, Maxwell's

> presence in the country soon attracted the suspicions of the Czech Ministry of the Interior[....]
>
> Springer-Verlag had published books by most of the world's leading scientists, including Albert Einstein and Max Born, the father of quantum mechanics. They also published a large range of scientific journals. The beauty of the business was that the books and journals they produced had a captive readership: every library, every university, every scientific institute, wanted a copy. What's more, the scientists who wrote these books and journals were so thrilled to see their work in print that they scarcely expected to be paid anything in return. [...]
>
> No new academic research had been published during the war, and as a result, Springer had a colossal backlog of material. Sixty-three thousand books, along with tens of thousands of journals, had been removed from Berlin and stored in an enormous warehouse a hundred miles away to escape the Allied bombing. There was also a huge amount of scientific research conducted during the war that had never even been printed due to lack of paper.
>
> [...A]t the time German nationals were forbidden from making large shipments to other countries. Springer was convinced the demand was there. All over the world academics were dying to read about the latest research[....]
>
> In November 1947, 369 'large packets' were sent from Germany to London. By then, Maxwell had been demobbed from the army and had gone back to England to be with Betty and their baby son. He had also secured worldwide distribution rights to all of Springer-Verlag's publications. Four months later, 150 tons of books and another 150 tons of journals were loaded on to a goods train and taken to Bielefeld in western Germany. From there, a convoy of trucks brought them to London. These were followed by another enormous consignment of manuscripts—so large that seven railway carriages were needed to transport it[....]
>
> Where did Maxwell get the money from to set up in business? Certainly not from Ferdinand Springer, who was in no position to fund anything at the time. [...]
>
> Shortly before his death in 2000, Desmond Bristow, a former Intelligence Officer, spoke about MI6's relations with Maxwell: 'It was obvious that Maxwell had been doing odd things for MI6 in Germany, and he suggested we should subsidize him to buy a book business. He effectively became our agent. [...] I was certainly not aware of any other case of MI6 buying a business for anyone.'

After being placed in charge of a (mostly captured German) scientific publishing empire by the intelligence community, Hoch/Maxwell went on to enrich himself by wining and dining influential scientists to persuade them to publish more and more papers and to create more and more scientific journals [Buranyi 2017; Francis 2020; Sarkowski 2001]. Thus Hoch/Maxwell was a highly influential force in corrupting the scientific community from its historical emphasis on publishing quality over quantity to its modern obsession with endless quantity (and exorbitant journal and book prices) while abandoning most concerns about quality, originality, or even correctness (pp. 50–51, 2245–2250, 2262–2263). Although the details are murky, Hoch/Maxwell seems to have had other unsavory effects on society, a tradition that was apparently continued by part of his family and by his younger associate Jeffrey Epstein [p. 2251 and Preston 2021].



Tons of German documents referring to aeronautics are studied by technicians. Two men at left are German, two at right are American.

Figure 11.32: German and U.S. scientists sorting and translating “tons” of captured German and Austrian technical documents at Wright Field, Ohio, in 1946 [*Dayton Daily News*, 8 December 1946, p. 55]. See also p. 5263.

For historians, even worse than the Allied *removal* of German-language documents was the intentional and systematic Allied *destruction* of German-language documents. As shown in Figs. 11.35–11.36, postwar Allied reports explicitly discussed "the denial of certain archives, records, and papers to the Germans" by "the organized destruction of papers... which must not be permitted to fall into German hands after the departure of occupation forces" [NARA RG 40, Entry UD-75, Box 62, Report German Documents Conference].

Unfortunately, those plans for the wholesale destruction of historical documents were not only discussed but actually carried out. Michael Howard was an intelligence officer in the British T-Force, which investigated and removed vast amounts of German technology, including German documents. In two different sections of his memoir, he described the large-scale destruction of documents in the years and decades after the war, in order to forever bury the actual historical events [Howard 2010, pp. 253, 334]:

> From about 1948 the Control Commission for Germany began to destroy their files and documents, and this continued until 1956 when the remaining 240 tons were brought back to the UK. Then the Foreign Office set about them, employing mostly retired officials who had been given a brief, the details of which were never disclosed, but which did not leave much to chance. Today, less than two tons of those documents remain. It was a deliberate attempt to make the task of writing a complete history of a unit whose very name was not to be voiced in the public domain very difficult. Great care has been taken to prevent a cataloguing of what we took out, and above all to avoid setting a monetary value upon it. [...]
>
> The records and documents of the Control Commission for Germany [CCG], including those of T-Force, came ultimately under the aegis of the Foreign & Commonwealth Office, and in 1983 I corresponded with Ellie Blaney, head of the FCO Library and Records. From her I learned that a large quantity of CCG files, including those of T-Force, were destroyed in Germany between 1948 and 1956. The remainder, some 240 tons, were brought to the UK where the destruction continued unabated to the point where by 1986 less than two tons remained. Much of this material remained secret, even after forty years, and some remains so even today (in particular, I suspect, any that quantify the monetary value of the depredations of T-Force). It is still a sensitive and controversial subject.

What quantities of German documents were destroyed by the Allies?

What information did those documents contain that prompted the Allies to destroy them?

Were any copies or microfilms of those documents retained in any countries?

HEADQUARTERS
U.S. FORCES, EUROPEAN THEATER
Office of the A.C. of S., G-2

OPENING STATEMENT OF THE CHAIRMAN

Mission of the Document Conference.

The mission of the Document Conference is the recommendation and formulation of the most effective standard operating procedures for the handling of documents, archives, and records captured and seized in the occupation zones under control of United States Forces, European Theater and United States Forces, Austria. The conference is also to deal with proposals to be formulated for quadrupartite consideration on the destruction of documents, archives, and records which are of no value to the Allies, and which must be denied to the Germans.

Details of Conference.

The Document Conference is being conducted by the Documents Control Section, United States Forces, European Theater, at the direction of the A.C. of S., G-2, Headquarters, United States Forces, European Theater.

Date: 22 October 1945

Place: G-2 Conference Room, Headquarters, United States Forces, European Theater.

Represented:

War Department General Staff
Berlin District
United States Forces, European Theater
London Military Document Center
Office of Military Government for Germany (U.S.)
  Director of Intelligence
Third U.S. Army (Eastern Military District)
Seventh U.S. Army (Western Military District)
United States Forces, Austria
Field Information Agency, Technical
United States Air Forces in Europe
Bremen Sub-District
United States Naval Forces, Europe
United States Naval Forces, Germany

Observers:

A.C. of S., G-3, U.S. Forces, European Theater
Office of Military Government (U.S. Zone)
  Monuments and Fine Arts
Military Attache, U.S. Embassy, London
Judge Advocate General, War Crimes Commission
Office of Chief of Counsel (US) for Prosecution of
  Axis Criminality
Library of Congress Mission, Europe
Theater Service Forces, European Theater, G-2
Office of Military Government for Germany (US)
  Reparation, Delivery and Restitution
Central Tracing Bureau and Records Office, UNRRA

Figure 11.35: Postwar Allied reports explicitly discussed "the denial of certain archives, records, and papers to the Germans" by "the organized destruction of papers... which must not be permitted to fall into German hands after the departure of occupation forces" [NARA RG 40, Entry UD-75, Box 62, Report German Documents Conference].

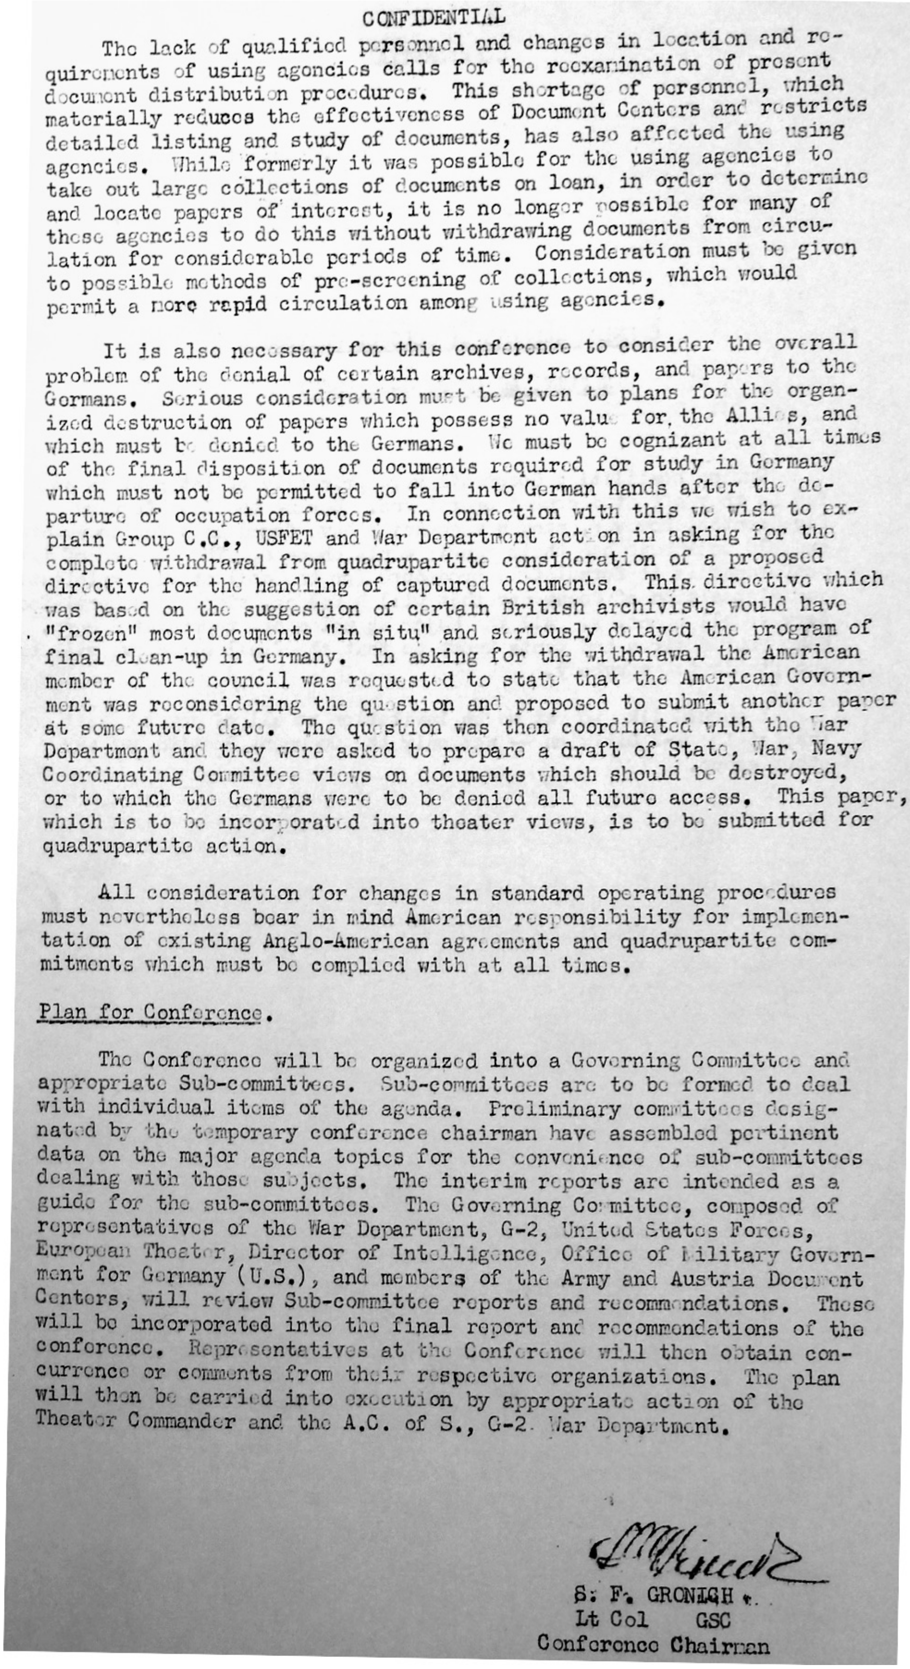
NARA RG 40, Entry UD-75, Box 62, Report German Documents Conference p. 5



CONFIDENTIAL

The lack of qualified personnel and changes in location and requirements of using agencies calls for the reexamination of present document distribution procedures. This shortage of personnel, which materially reduces the effectiveness of Document Centers and restricts detailed listing and study of documents, has also affected the using agencies. While formerly it was possible for the using agencies to take out large collections of documents on loan, in order to determine and locate papers of interest, it is no longer possible for many of these agencies to do this without withdrawing documents from circulation for considerable periods of time. Consideration must be given to possible methods of pre-screening of collections, which would permit a more rapid circulation among using agencies.

It is also necessary for this conference to consider the overall problem of the denial of certain archives, records, and papers to the Germans. Serious consideration must be given to plans for the organized destruction of papers which possess no value for the Allies, and which must be denied to the Germans. We must be cognizant at all times of the final disposition of documents required for study in Germany which must not be permitted to fall into German hands after the departure of occupation forces. In connection with this we wish to explain Group C.C., USFET and War Department action in asking for the complete withdrawal from quadrupartite consideration of a proposed directive for the handling of captured documents. This directive which was based on the suggestion of certain British archivists would have "frozen" most documents "in situ" and seriously delayed the program of final clean-up in Germany. In asking for the withdrawal the American member of the council was requested to state that the American Government was reconsidering the question and proposed to submit another paper at some future date. The question was then coordinated with the War Department and they were asked to prepare a draft of State, War, Navy Coordinating Committee views on documents which should be destroyed, or to which the Germans were to be denied all future access. This paper, which is to be incorporated into theater views, is to be submitted for quadrupartite action.

All consideration for changes in standard operating procedures must nevertheless bear in mind American responsibility for implementation of existing Anglo-American agreements and quadrupartite commitments which must be complied with at all times.

Plan for Conference.

The Conference will be organized into a Governing Committee and appropriate Sub-committees. Sub-committees are to be formed to deal with individual items of the agenda. Preliminary committees designated by the temporary conference chairman have assembled pertinent data on the major agenda topics for the convenience of sub-committees dealing with those subjects. The interim reports are intended as a guide for the sub-committees. The Governing Committee, composed of representatives of the War Department, G-2, United States Forces, European Theater, Director of Intelligence, Office of Military Government for Germany (U.S.), and members of the Army and Austria Document Centers, will review Sub-committee reports and recommendations. These will be incorporated into the final report and recommendations of the conference. Representatives at the Conference will then obtain concurrence or comments from their respective organizations. The plan will then be carried into execution by appropriate action of the Theater Commander and the A.C. of S., G-2, War Department.

S. F. GRONICH
Lt Col GSC
Conference Chairman

Figure 11.36: Postwar Allied reports explicitly discussed “the denial of certain archives, records, and papers to the Germans” by “the organized destruction of papers... which must not be permitted to fall into German hands after the departure of occupation forces” [NARA RG 40, Entry UD-75, Box 62, Report German Documents Conference].

Postwar transferred English-language documentation

Beginning even before the war ended and continuing for several years afterward, the United States and United Kingdom sent many thousands of government, university, and industrial investigators into areas formerly controlled by the Third Reich to interview German-speaking scientists and engineers. Under threat of imprisonment—for example at facilities such as "Dustbin" in Germany (p. 2126), "Halstead Exploitation Centre" in the United Kingdom (pp. 2127–2129), or Fort Hunt in the United States (pp. 2045, 4883)—or execution for war crimes, the scientists and engineers were "interrogated" (as the Allies openly called it) for anywhere from days to months at a time, or even repeatedly by different investigators for years after the war, and required to give the Allied investigators detailed explanations, documentation, and hardware for all of their work. In many cases, as described afterward by German-speaking scientists, Allied investigators did not even properly identify themselves, and simply seized all copies of a scientist's work, leaving no trace of where those copies ultimately went.

This policy applied to all research and development activities, not just those with military histories or potential. Allied investigators inspected and wrote detailed reports on the manufacture of items as diverse and as non-military as German:

- Planetarium projectors [BIOS 218].
- Harmonicas [BIOS 227].
- Ice skates [BIOS 506].
- Mattress springs [BIOS 601].
- Fishing rods [BIOS 1086].
- Spoons and forks [BIOS 1647].
- Sewing thread [FIAT 308–312].

Reports such as BIOS 769 (*German Manufacture of Sewing Machines, Garment Making Machines, Cloth Cutting Machines, Sewing Machine Needles*) gave detailed lists of documents and machines to be "evacuated" from Germany and Austria to the United States and United Kingdom for "research" purposes.

In fact, Allied investigators combed not only former Axis countries and territory for innovations they could harvest, but Switzerland as well, even though Switzerland had remained neutral and independent in the war. Numerous reports documented such investigations in Switzerland [e.g., BIOS 1417; CIOS XXXI-22; FIAT 306; FIAT 509]. According to the U.S. State Department's own documents, in 1946 the United States tried to forcibly conscript Jakob Ackeret (1898–1981), even though he was a Swiss citizen, had been born in Zurich, and was a well-known professor of aerodynamics who had been teaching at the university in Zurich since 1931 (pp. 5395–5396). Based on the number of published Allied reports openly documenting their own lack of regard for Swiss sovereignty and intellectual property, it seems unlikely that Ackeret's case was unique.

Even German doll makers and the stuffed toy manufacturer Steiff were exhaustively mined for any design or production secrets that could help U.S. and U.K. toy manufacturers out-compete them in the postwar market [Gimbel 1990a, pp. 165–166; BIOS 1371; BIOS 1622].

That brazen exploitation continued for many years after the war. Mattel's iconic Barbie doll (1959) was directly copied from the earlier German Bild Lilli doll created by Reinhard Beuthien (German, 1911–1970) and Max Weissbrodt (German, 19??–19??). Ruth Handler, the American who claimed to have "invented" Barbie, made millions of dollars, while the true inventors Beuthien and Weissbrodt were largely forgotten [Warnecke 1995]. Toward the end of her life, in 1997, Handler gave an interview in which she confessed that she had simply copied the Lilli doll [BBC 2023]:

> Ruth Handler and her husband Elliot founded the toy company Mattel in a garage workshop in Southern California in 1945; she came up with the idea for the Barbie doll, which was launched in 1959. [...]
>
> Handler had an epiphany, however, when the family went on holiday to Switzerland.
>
> RH: We passed a toy store and there in the window was a beautiful display of an adult-figured doll about 11.5, 12 inches tall, and this doll was sitting on a rope swing dressed in a very European ski clothes, and there were six or seven other of the same dolls each with a different European type ski outfit, where Barbara and I thought the dolls were just gorgeous. We just flipped—the doll's name was Lilli.
>
> A German doll based on a comic strip published in a national newspaper, Lilli was marketed to both children and adults. Even though she was then 15 [in 1956], Barbara wanted one.
>
> RH: She couldn't make up her mind which one she wanted because each ski outfit was different. And so I said to the lady in the store, "Can I buy this style and buy that costume?" And the lady in the store looked at me as if I was nuts. Only a crazy American would ask such a silly question. She said: "No, you want that costume, you buy that doll; you want this costume, you buy this doll." By then my mind had clicked.

Kransberg Castle, or "Dustbin" for 1945–1946 interrogations

See also pp. 4166–4169 and 5010.

The total number of U.S. and U.K. investigators is unclear from existing records, but may well have greatly exceeded the number of German-speaking scientists and engineers being interrogated.

Between 22 August 1944 and 13 July 1945, at least 2197 different U.S. and U.K. investigators visited at least 3377 separate scientific targets (places and/or people) in Europe on behalf of CIOS [AFHRA A5186 electronic version pp. 904–1026, Ch. 4, pp. 29–30]. Those numbers do not include investigators or locations visited during that time by organizations other than CIOS.

The number of U.S. investigators who visited between July 1945 and June 1946 is difficult to locate but must have numbered in the thousands. At least 4994 U.S. FIAT (Field Information Agency, Technical) investigators visited Germany during the 12-month period of 1 July 1946–30 June 1947 [Gimbel 1990a, p. 79]. Of course, that number does not include U.S. investigators from agencies other than FIAT, or investigators from other countries.

At least 1300 U.K. investigators visited Germany just during July–August 1945, and at least 2800 more between then and February 1946 [Glatt 1994, p. 163].

A 1947 *New York Times* article stated that at least 6000 U.S. industry experts had been sent to Germany in search of files, patents, and factories [NYT 1947-05-26 p. 35]:

> German Secrets Net U.S. $1,500,000: 400,000 Copies of Documents Already Sold to Industry—Russia Good Customer.
>
> The United States is collecting reparations from Germany at the rate of $6,000 a week from sale of Nazi wartime technical and scientific inventions.
>
> To date, sale of these hitherto secret inventions and scientific reports to American citizens and corporations has yielded the Commerce Department a gross revenue of $1,500,000, and the amount is still growing.
>
> This has been disclosed by John C. Green, director of the new Office of Technical Services, whose 600 employees have been collecting, classifying and microfilming German patents and documents since the end of the war.
>
> More than 400,000 copies of scientific documents, according to Mr. Green, already have been sold to American concerns at an average fee of $3 to $4 a document. He estimates new orders are coming in from American businessmen at the rate of 1,000 a day.
>
> Mr. Green says that, to his knowledge, this is the only Federal agency in Washington currently collecting reparations from Germany.
>
> Since the end of the war, the agency has processed 75,000 original technological reports and still has on hand 2,000 truckloads—with an estimated 400,000 unprocessed documents—which have been shipped here from Germany.
>
> Many of the processes and inventions are considered “priceless” by officials. Several large United States corporations are said to have been willing to pay as high as $20,000,000 for exclusive rights to a German process.
>
> The Government, however, has laid down the policy that seized scientific information is to be made available to all comers at nominal fees.

> Under this policy, it is estimated that the Russian Government has purchased $17,000 worth of documents totaling nearly 5,000 separate items. The Russian purchasing agency, Amtorg, has been ordering documents at a token price since last year, according to officials.
>
> Although Commerce Department officials at first were reluctant to sell the information to the Russian Government, the State Department laid down the policy that reports should be sold to Amtorg because the material is being made public and anyone could write in and get it.
>
> The German "brain-picking" project is the joint venture of business and Government. To help Commerce employees dig out the documents, United States industry sent 6,000 experts of its own to Germany in the search of I. G. Farben files, patents and factories. [...]

Many documents from this time testify to the large number of investigators who visited individual German and Austrian scientists. For example, BIOS 100, *Development of Panzerfaust*, pp. 1, 15 recorded the visitors (most of whom were apparently not even from known U.S. agencies) for two different scientists, Drs. Langweiler and Kittel (see also p. 558):

> Dr. LANGWEILER [the inventor of Panzerfaust] stated that he had been interviewed 16 times before. On each occasion some of his documents and equipment had been removed. He was finally left with only an incomplete set of drawings of PANZERFAUST 150. No record or report of any of these previous interviews can be found by the writers of this report. [...]
>
> Kittel stated that he had been interrogated in June by an American officer and an American technician. No record of this interrogation can be traced at FIAT, USFET, Third US Army, or Seventh US Army. It is recommended that the report on this previous interrogation should be obtained and circulated to the organisations concerned.

Similarly, BIOS 115, *Report on the Interrogation of Dr. Kurt Stenge*, p. 3, reported the treatment of Dr. Stenge prior to his latest (but probably not last) interrogation:

> Dr. STENGE had previously been kept for a month at Paris where he was submitted to several interrogations, mainly by American investigators, but including one by Commander STUDDERT (sie), R.N. Subsequent to this he lived near MAGDEBURG where he was visited by Commander WASHBURN, R.N., who was stated to have removed all his records.

As another example, the most recent Allied investigators to interrogate Robert Pohl, a solid state physics professor, were surprised that he was not immediately thrilled to see them after all of his previous Allied interrogators (BIOS 870, *Physics of the Solid State*, p. 4):

> Professor Pohl was inclined at first to be cold and formal, presumably because he had been investigated by rather a large number of people in British uniform, but he warmed up increasingly as he understood how much our interests had in common with his own, and from then on the visit was a great success.

Describing the investigators, the *New York Times* wrote [NYT 1947-02-23 pp. SM33–35]:

An American invasion of Germany which started even before V-E Day is now at the peak of operations, with its mission approximately half completed. It is made up of business men, scholars, researchers and technical experts, military and civilian, who have been ferreting out German secrets of science and industry, particularly Nazi wartime developments. [...]

The dollar value of these discoveries cannot be accurately estimated. Yet, an indication was given when an official of the I. G. Farben Company in Germany, handing over a chemical formula to a member of the Commerce Department's Office of Technical Service, which directs the operation, said: "We spent $500,000 in developing this process."

American action in taking these data from Germany gives a new meaning to the old adage that "To the victor belong the spoils," points out John C. Green, director of the OTS. "We are giving worldwide distribution to scientific knowledge; already nationals of twenty-eight countries have received our reports. And, in addition, we are blasting the German-controlled cartels." [...]

Today a startling number of products and processes which offer considerable promise have already been analyzed and are being publicized. Among these are the magnetophone, a sound-recording and reproducing machine using plastic tape (coated with iron oxide) instead of disks, and magnetism instead of needles; a "negative-positive" process for colored moving pictures which accomplishes in two steps what now requires nine; a superior photoelectric cell, used particularly in speaking along a beam of light; an ingenious "fixed paper" condenser; a butter-making machine, and improved processes in mass production of radar and radio chassis, in supersonics, and in acetylene and carbon monoxide chemistry. [...]

Several German cinema films made with the new color process have been exhibited in the Commerce Building in Washington, notably "The Girl of My Dreams" and "Golden City." The color has been described almost lyrically by reviewers. A report on this process is scheduled for release soon.

The "Gudden" photoelectric cell—twenty to fifty times more sensitive than any developed in the United States—was used by the Nazis in the war through the "photophone." With this outfit persons several miles apart, and in situations where telephone wires cannot be strung, can converse over a beam of visible light or invisible infra-red light.

The "fixed paper" condenser, developed by the Robert Bosch Company, is of interest to American makers of electrical and electronic systems, automobiles, radio sets and radar equipment. In it the usual metal foil is replaced by a very thin, vaporized zinc coating, applied directly onto paper separators. Its special features are that it is smaller, cheaper, "heals" automatically after breakdown and may be operated at from 20 to 50 per cent higher voltages than is possible with paper-and-foil capacitors. [...]

The German acetylene processes may turn out to be the most valuable of all, in the making of plastics, drugs, dyes and fuels.

These devices, with hundreds of others, are now finding their way into the hands of American manufacturers for close study.

These U.S. and U.K. investigators wrote over 8000 English-language reports, as shown in Table 11.7.

Table 11.7: Some major series of English-language reports on German creations.

The U.S. and U.K. governments made almost all of those reports available to anyone (even the Soviet Union) simply for the printing costs of each report copy [Gimbel 1990a, pp. 96, 101]:

> The subjects of the reports offered for sale by the OTS touched virtually every aspect of German industry and technology: acetylene chemistry, synthetic fuels and rubber, synthetic lubricating oils, synthetic fibers and textile manufacturing, ceramics, diesel motors, optics and glass, wind tunnels, heavy presses, infrared, tape recorders and metalized plastic tapes, cold extrusion of steel, electron microscopes, electric condensers, a butter-making machine, fruit juices, a machine to wrap chocolates, a process to preserve soybean oil, white carbon black, cellulose products and wood sugars, dental supplies, synthetic mica flakes, synthetic sapphires for watch, clock, and instrument bearings, color film and color-film processing, quartz clocks, pharmaceuticals, insecticides, synthetic blood plasma, artificial leather, plastics, colors and dyes, soaps and detergents, woodworking machinery, slide fasteners, sewing needles, cheese-making equipment, potentiometers and other precise measuring instruments, milk cans, manure spreaders, motorcycles, and cameras and photographic equipment, among other things.

> Neither the investigators who wrote the Publication Board reports nor the firms that bought them from OTS were obligated to report back on how the reports were used or on the benefits derived from them. Some of them did, however, thus providing a few insights into what remains essentially a closed book.
>
> [...] In May 1947, Robert Reiss, of OTS, listed—albeit without giving details—the names of seven companies known to be using the German acetylene chemical processes, three companies using German circuit-breaker technology, two companies using synthetic mica developed in Germany, two companies using the Fischer-Tropsch synthetic fuels technology brought from Germany, and individual firms that were using information from Germany on radio condensers, tape recorders, phase-contrast microscopes, cold extrusion of steel, and synthetic fibers.

Even though U.S. companies spent a great deal of time and money sending investigators to interview German-speaking creators and procuring copies of English and German documentation on their work, and then soon thereafter produced new products bearing a remarkable resemblance to those German creations, U.S. companies were loath to publicly admit any direct transfer of technological knowledge [Gimbel 1990a, pp. 224 note 26]:

> It is indicative of how hard it is to come by information on American companies' use of German technology that after John C. Green presented some of Reiss's information in testimony before Congress, some firms denied vigorously that they had, in fact, used or benefitted from German technology. For example, Bruce K. Brown, of the Standard Oil Company, denied Green's assertion that Stanolind Oil and Gas Company of Kansas was using Fischer-Tropsch process techniques, arguing that the information was available before the war and that the basic principles were generally known. U.S. research laboratories and pilot plants, he said, had existed in the United States "since well before World War II." But this argument flies in the face of the verifiable fact that the U.S. Technical Oil Mission swarmed over Germany in 1945 and that the American Petroleum Institute and the Bureau of Mines sent several follow-up missions to Germany to gather information on the Fischer-Tropsch process—information that, as we have seen elsewhere in this study, American industry and the American government continued to try to expropriate as late as 1951. [...] Further, W. A. Steiger, the patent attorney for Westinghouse Electric Company, wrote to Congressman Karl Stefan—also in response to Green's testimony before Congress—that the OTS/FIAT operation had been useless to his company. "So far as our company is concerned, I have investigated the situation, and it is my personal opinion that this particular Government activity is of no value to us." [...] Green reacted by informing Steiger that OTS records showed that between 1945 and Feb. 1948, Westinghouse had purchased 388 copies of reports...

Postwar transferred unwritten knowledge

In addition to technical knowledge transferred via documentation written in German or English, a vast amount of knowledge was transferred in unwritten form.

One route for unwritten transfer was of course the knowledge and work of the more than 6000 German-speaking scientists and engineers who ultimately moved to the United States [Mick 2000, p. 316], the more than 9000 who worked for the Soviet Union either in the Soviet Union or in East Germany [Mick 2000, pp. 15–17; Naimark 1995, pp. 230–232], and the thousands of others who worked for the United Kingdom, France, and other countries.

However, a less well known yet still pervasive and highly influential form of unwritten knowledge transfer occurred as the many thousands of Allied investigators took information that they did not record in their reports [Gimbel 1990a, pp. 107–112]:

> These reports and other records of FIAT and OTS provide a basis for illustrating the nature of the scientific and technical know-how removed from Germany, but much of what the Americans gained and the Germans lost remained unreported.
>
> *Incomplete Reports.* Investigators, who were not required to discuss their reasons for wanting to visit specific targets if they thought doing so would reveal industrial or trade secrets of their own, often spent days and weeks at a given location in Germany without including more than a passing reference in their reports to what they did there. Sometimes they admitted quite frankly that they had been "exposed to all sorts of little interesting gadgets and tricks of the trade which are too numerous and detailed, it is believed, to cover in this report." Echoing those words, a FIAT summary report of 20 November 1946 talked about "the various bits of 'know-how', the gadgets and 'tricks of the trade' which investigators observe in passing through the plants, possibly making no particular mental note or record at the time" but which they can use "later when back on the job and facing a problem where the same application can be made." The OTS director, John C. Green, who praised his operation publicly as the source of "the only solid and permanent reparations we are going to get out of this war" and as the provider of "intellectual reparations, prizes of victory which can be shared by every American businessman," nevertheless noted that "in countless cases, a process, device, or tool observed by an investigator in Germany will be passed on to an American firm to increase efficiency and lower costs." Furthermore, in at least one instance he admitted privately that investigators and document screeners were "pocketing some information they obtained instead of including it in their reports or contributing it to microfilmed material."
>
> *Inadequate Reports.* [...] As a case in point Green mentioned the two FIAT reports by C. H. Reynolds, of the Sheffield Corporation, which were judged by the Publication Board to be so poorly done as to be unpublishable, even though Reynolds's own company considered his findings important enough to send him and one of his colleagues back to Germany for more detailed investigations. Meanwhile, the rest of the industry knew nothing of the details of what Reynolds had learned, although they knew about it in general. FIAT's response, though devoid of solutions, shows that Green's case in point was but the tip of the iceberg. [...]

> *No Reports.* In a letter of 11 April 1946 to the Office of Military Government for Germany (OMGUS), whose field-branch office in Stuttgart had complained that FIAT operations were little more than a conveyor belt for industrial espionage, Colonel Ralph M. Osborne, the U.S. chief of FIAT, wrote that even though investigators came from private firms, all of them were under government contracts requiring them to report their findings and prohibiting them from using their positions to secure special information for their own firms. [...]
>
> Without-compensation (WOC) investigators often did not cooperate. Some of them had obviously used FIAT "as a pretext to get into Germany" to conduct their own private affairs; those who had previous business connections in Germany were particularly hard to handle. Many investigators simply used target-assessment reports in the FIAT files as models for their own perfunctory final reports; some of them refused to write reports; and others who had initially refused to write reports wrote inadequate ones when they were pressured to do so.
>
> OTS's solution to the problem of incomplete, inadequate, and nonexistent reports was to open the floodgates and send as many people to Germany as it could, presumably so that as many as possible could get what they wanted for themselves. [...]
>
> In February 1947, John C. Green [...] published "Last Call for Germany." "The opportunity to enter any factory, see any documents, inspect any equipment and interrogate any expert cannot last indefinitely," he warned. "This is American industry's last chance to acquire, at small cost, a wealth of scientific and technical information." [...] Green observed that "victory opened the doors and the files of German factories and laboratories to American investigators." He concluded that "it will be a national tragedy... if we allow the doors to shut before we have added all of the best of Germany's technical knowledge to our own."

Describing this form of unwritten knowledge transfer, Bradley Dewey, president of the American Chemical Society, remarked [Gimbel 1990a, p. 227]:

> ...that most valuable material is not in reports but in the ideas which [the] investigator keeps in his own head.

Postwar influence on the structure of the U.S. research system

Many of the general approaches that had made the German-speaking world so effective at producing revolutionary creators and creations were at least temporarily adopted by the United States research system. As discussed in Section 11.2, those general approaches played a critical role in the successes of the U.S. R&D programs during the 1940s–1960s. Unfortunately, the abandonment of those approaches after that period seems to have greatly contributed to the steady decline in revolutionary innovation from the 1970s to the present, as described in Section 11.3.

Net impact

From archival documents and authoritative sources, it seems clear that:

- By the first several decades of the twentieth century, German-speaking scientists and engineers were generally many years ahead of others in biology and medicine, chemistry and materials science, earth and space science, applied mathematics and physics, electrical and electromagnetic engineering, mechanical engineering, nuclear science and engineering, and aerospace engineering. In many fields, they were over a decade ahead of everyone else, according to postwar Allied investigators.

- German-speaking creators and their creations played critical roles in advancing the scientific and technological levels of other countries in all of those fields to some extent before and during World War II (due to scientific refugees and published information) and to an enormous degree after the war.

- The transfer of German-speaking creators and creations to the United States, United Kingdom, France, Soviet Union, and other countries was equivalent to the transfer of a vast amount of wealth, including past financial investments in making the discoveries and inventions, then-current and future financial income from products based on the discoveries and inventions, and the sheer economic value of thousands of factories, countless amounts of equipment and materials, and thousands of trained specialists that were physically transferred. Allied countries publicly described that transfer as “reparations” and continued to benefit from it for decades after the end of World War II. Germany and Austria suffered the corresponding loss.

In June 1945, U.S. Assistant Secretary of State William L. Clayton testified before the U.S. Senate, openly describing the Allied plan for systematically removing scientific innovations from Germany and Austria [Clayton 1945, pp. 34–37]:

> I should like now to turn to certain questions related to German technological information and scientific research. If we are prepared to acknowledge that German research and scientific development have been important in the past, we must also be prepared to draw the obvious conclusion that the exclusive possession or control of certain kinds of advanced technology by German nationals involves a possible danger to our security and provides German nationals with important assets which in the past have induced other parties to join them in international cartel arrangements.
>
> Our intentions with respect to German research and scientific information may be summarized as follows:
>
> 1. We intend to secure the full disclosure of all existing German technology and invention for the benefit of the United Nations.
>
> 2. Through seizure by the Governments of the United Nations of German-owned patent rights on inventions developed before and during the war, we shall be able to withhold from German nationals the usual technological assets which have proved to be the main inducements for other parties to join the Germans in international cartel arrangements.

> 3. We intend to allow organized research and invention in Germany during the period of military occupation only when we are fully satisfied that such research will not contribute to Germany's future war potential.
>
> [...] Naturally, a considerable portion of the acquired enemy technology has been assigned secret status by the U.K.-U.S. military authorities, since it is in the interest of the two governments that certain classes of information should not be directly or indirectly disclosed to our remaining enemy.

In this testimony before the U.S. Senate, the State Department stated that most revolutionary scientific innovations had been coming exclusively from the German-speaking world. The State Department further admitted that the United States and other countries were not developing revolutionary innovations such as those, which put them at a great economic and military disadvantage.

The solution proposed by the United States was for Allied countries to seize all revolutionary innovations and information on them from the German-speaking world, deny the German-speaking world the right to use its own innovations or economic income from them, and prevent the German-speaking world from creating new revolutionary innovations. The officials did not propose that the United States and other countries should invest the careful thought, funding, labor, time, and effort necessary to create large numbers of new revolutionary innovations of their own; they only proposed to exploit the existing German innovations they seized. Their proposed solution also involved classifying and burying "a considerable portion" of the acquired technology.[8]

In September 1945, R. P. Linstead and T. J. Betts, the British and American chairs of the Combined Intelligence Objectives Subcommittee (CIOS), declared [Fig. 11.41, AFHRA A5186 electronic version pp. 904–1026, Foreword, p. 5]:

> The effective exploitation of German technical development has proven one of the significant results accruing from the conduct of the European War. The value of the scientific knowledge and "know how" thus obtained cannot now be fully measured. That this intelligence contributed to the defeat of Japan is well established. The benefits of this knowledge to British and US industry will be measured in terms of economic progress and well-being for many years to come.

These conclusions regarding the value of German technology that could be "exploited" as "reparations" by Allied countries were publicly stated by people from high-ranking government officials to journalists at that time. A good example from the press is Ian Bevin, Germany Disgorges Her Rich Secrets, *News Chronicle* (London) 21 February 1946 p. 2 (which made extensive use of the September 1945 Linstead and Betts report):

---

[8] As demonstrated by the relative dearth of truly new revolutionary innovations over the following decades, that is basically what indeed happened. The United States and other countries harvested and consumed the entire crop of revolutionary innovators and innovations that the German-speaking world had been cultivating for many decades, yet ultimately proved unwilling to properly cultivate a whole new crop of innovators and innovations of their own, or to allow the German-speaking world to properly cultivate a new crop of innovators and innovations. The whole system that had produced so many revolutionary innovators and innovations for over 150 years was deliberately sacrificed for short-term enrichment, resulting in the world of relative stagnation in which we have been living ever since (Sections 1.1 and 11.3). Moreover, apparently many details of the original German-speaking work still remain classified or otherwise buried, depriving historians, scientists, and the public of the knowledge of what truly happened before, during, and after World War II.

> Allied agents have unearthed information of inestimable industrial value. [...]
>
> Technical and scientific knowledge gleaned from conquered Germany has provided the first great reparations payment to the Allies. [...]
>
> Just how the Governments will dispose of German industrial secrets to competitive private enterprises is not yet clear, but, as the information gained from Germany is regarded as a form of reparations, it will presumably be used for national rather than private gain. [...]
>
> These [long list of examples] are only a few of the thousands of discoveries made by CIOS, ranging from major industrial secrets to minor points of manufacturing technique, and adding up to one of the richest war prizes any victor could hope for. All that remains is for the Allies to use the information they have gained, and not let it lie forgotten in the files of Government departments.

For other examples of contemporary press reports, see the *American Magazine* article on p. 2050, *Harper's Magazine* article on p. 2114, and *New York Times* articles on pp. 2130 and 2131.

In March 1946, U.S. Army Colonel Ernest Gruhn, the first director of the Joint Intelligence Objectives Agency, wrote an amazingly candid draft press release that described how dependent the United States was not only on the massive postwar influx of German-speaking creators and creations, but also on earlier German-speaking immigrant scientists as well [Figs. 11.42–11.46. Ernest Gruhn. 14 March 1946. Exploitation of Germany for Technological and Scientific Information. NARA RG 330, Entry A1-1A, Box 4, Folder 383.7 Policy–1946.]:

> After World War I there was no real attempt by the victors to exploit Germany for technical and scientific knowledge. However, long before World War II with Germany had ended, plans were made by the Joint Chiefs of Staff for the complete exploitation of Germany for technical information.
>
> In accordance with these plans, the government is now engaged in exploiting Germany for all the technical and scientific information that can be obtained. Exploitation has involved the sending of several hundred highly qualified American technicians and scientists into Germany close upon the heels of our conquering armies. These investigators have examined manufacturing plans and equipment, records and documents and have interrogated German personnel. The information of industrial value that has been collected is being made available to the public by the Department of Commerce.
>
> Steps are now being taken to extend this exploitation by bringing the best German scientists and technicians to this country so that their talents can be used here. [...]
>
> In the past, the United States has depended to a considerable extent upon German scientists for pure basic scientific research. Such research forms the basis of practical developments. [...]
>
> The exploitation of these highly trained Germans will be of great value to the development of new types of weapons which were being planned by the Germans as the war

> ended. It will also be in the national interest to use them to increase our production potential in many industrial fields. [...]
>
> Closely related to the exploitation of German scientists and technicians is the government program for exploitation of German developments in industrial machinery, tool, equipment and materials. Samples of these are being procured through reparations procedures for shipment to the United States where they are made available for study by American industry on a non-restrictive open-to-the-public basis.
>
> From the above, it is evident that the government is using vacuum cleaner methods to acquire all the technical and scientific information that the Germans have. The value of this information to the United States will probably far exceed any cash reparations.

The U.S. Joint Chiefs of Staff responded to Colonel Gruhn's proposed press release by immediately classifying and burying it; see Fig. 11.47.

In June 1946, U.S. Army Air Forces Major General Curtis LeMay did give a public assessment of the German-language materials transferred after the war [LeMay 1946]:

> At Wright Field, O[hio]., German scientists are now assisting American scientists in translating great masses of captured German scientific documents. These documents reveal, as the materiel at Freeman Field indicates, the extent to which German science had out-distanced American science in basic and applied scientific research and in aircraft development. It has been estimated that the Germans were 10 to 15 years ahead of us in fundamental research.

(For a closely related document, see p. 5263.)

This same estimate that German-speaking innovators were at least a decade ahead of the United States and other countries in a wide variety of fields was independently given by other sources (e.g., pp. 422, 2116). For example, the *New York Times* reported [NYT 1947-05-17 p. 2]:

> German Scientists' Help Said To Save Us 10 Years
>
> The importation of 350 German scientists has "already put the United States ten years ahead of schedule in some fields of research and has saved millions of dollars in research costs," American Army headquarters said today.
>
> The German scientists in the United States are employed on such studies as guided missiles, supersonic planes, jet engines, cancer, photography, meteorology, metallurgy, textiles and cereals—all under the supervision of the War Department.
>
> However, headquarters said, "the War Department will begin soon to release German scientists to American industry under the supervision of the Department of Commerce."

U.S. Army Air Forces Major Alexander de Seversky, who led a five-month study of German technologies at the end of the war, wrote [De Seversky 1952, p. 603]:

> At the end of World War II the Germans were at least a decade ahead of the world in the development of jet engines and supersonic aerodynamics. [...] After V-E Day our scientists and engineers had the opportunity to survey German technological progress. Having secured the necessary data, they came home satisfied that they would be able to start where the Germans left off.

In January 1947, L. B. Kilgore from the U.S. Technical Industrial Intelligence Division (TIID) of the Department of Commerce explicitly described how much German-derived knowledge had been transferred to the United States and how important it was for the country [Figs. 11.48–11.50. L. B. Kilgore. 10 January 1947. Proposal for a Compendium of German War Time Technology, Draft No. 2. NARA RG 40, Entry UD-75, Box 3, Folder Inter-Office Memoranda: To and From Robert Reiss.]:

> The accumulation of the technical industrial information, which has resulted from the detailed investigations of the German industry for the past two years by this office, has reached such enormous proportions that it has become difficult to inform the public of the possible benefits available to it. This accumulation of information not only represents the greatest transfer of mass intelligence ever made from one country to another, but it also represents one of the most valuable acquisitions ever made by this country.

In December 1947, U.S. Air Force General Donald Putt explained that German and Austrian scientists were so far ahead of U.S. scientists in a wide range of fields that suitable American scientists could not be found for U.S. programs, that large numbers of German and Austrian scientists were now developing their creations for the U.S. military, and that the United States was making them work for substandard wages compared to what it paid other employees [Figs. 11.51–11.52. Donald Putt to Joseph McNarney. 10 December 1947. German Specialist Program at the Air Materiel Command, Tab F. AFHRA A2056 electronic p. 405–406.]:

> (a) With the exception of those eliminated by a continuous screening process during the one-year probationary period, all specialists now assigned to the various laboratories and activities of Air Materiel Command are outstanding in their respective scientific and engineering fields.
>
> The majority have specific talents and all were associated with German research and development during the war period.
>
> The majority were selected for their work in fields of aeronautical research, such as supersonics, jet and rocket engines, guided missiles, ceramics, jet and rocket fuels, etc., in which American technicians had little or no experience, due to emphasis being placed on other lines of development. Today, however, USAF development is concentrated on those fields in which the Germans had advanced beyond our own knowledge in those same fields.
>
> Millions of dollars were spent by the Germans in research in these fields. By utilization of the German specialists, the Air Force can start where German research left off, rather than spending many dollars of public funds repeating what has already been accomplished or determined to have been unsatisfactory. Not to take advantage of this possibility is short-sighted and unrealistic. [...]

> (e) The German specialists now on duty at Air Materiel Command have been and are now making significant contributions to the development of Air Force items of equipment and to technical and scientific literature. The specialists are an important cog in the Air Force research and development program. [...]
>
> (g) Salaries being paid to the German specialists are less than would be required for equivalent American technicians if they were available.

An official U.S. Air Force program history written in 1948 again stated that German scientists were many years ahead of their American counterparts [Fig. 11.56. Edna Jensen. 1948. *History of AAF Participation in Project Paperclip, May 1945–Mar 1947*, p. 44. AFHRA A2055 electronic p. 747]:

> Recommendations to the Commanding General, U.S. Strategic Air Forces in Europe (Lt. Gen. Carl Spaatz), from his Deputy (Maj. Gen. H. J. Knerr) included the comment, "Occupation of German scientific and industrial establishments has revealed the fact that we have been alarmingly backward in many fields of research. If we do not take this opportunity to seize the apparatus and the brains that developed it and put the combination back to work promptly, we will remain several years behind while we attempt to cover a field already exploited."

Another official U.S. Air Force history written in 1954 yet again confirmed that during and after World War II, German scientists were many years ahead of American scientists in a wide range of fields [Figs. 11.57–11.58. *History of the Air Research and Development Command.* 1954. Chapter IX. Dr. Charles A. Johnson. Project "Paperclip," pp. 258, 265. AFHRA K2838 (15390) electronic pp. 887, 894]:

> World War II had proven that Germany was many years ahead of the United States in a number of scientific and technical fields, notably in propulsion, jet and rocket engines, jet fuels, and guided missiles. While extensive know-how in these scientific areas was in the possession of many outstanding scientists and engineers living in Occupied Germany and the U.S. Zone of Austria, within the United States itself there was a particular shortage of knowledge.
>
> Colonel Donald L. Putt, leading the Air Force Intelligence teams that took over these German research laboratories and experimental stations, made this evaluation: "I visited a great many of them . . . . Their research progress in jet and rocket propulsion, aerodynamics, thermodynamics, supersonics, and other fields was clearly far ahead of anything of the kind we had done."

In 1949, the U.S. Army likewise admitted that German scientists were up to a decade ahead of the U.S. during the war and that in postwar U.S. programs, the German scientists were making enormous contributions in a wide variety of fields that were beyond the capabilities of U.S. scientists (pp. 4890–4892). Senator Harry Byrd reached the same conclusions (pp. 5492–5495).

No less an authority (and a very cautious and conservative one at that) than Dwight Eisenhower wrote in a secret 1945 cable to Washington D.C. that German scientists were even further ahead than that at the end of the war [Ordway and Sharpe 1979, p. 198; Mieczkowski 2013, p. 38]:

> Have in custody over 400 top research development personnel of Peenemünde. Developed V-2. [....] They are anxious to carry on research in whatever country will give them the opportunity, preferably US, second England, third, France. The thinking of the scientific directors of this group is 25 years ahead of US. [...] Immediate action is recommended to prevent loss of whole or part of this group to other interested agencies.

Of course, as illustrated by the evidence throughout this book, it was not only the abstract scientific thinking of the German experts that was years ahead of the United States, but also their test facilities, prototypes, experimental demonstrations, industrial mass production, and use of those new technologies.

The United States was not the only country to benefit from German-speaking creators and their creations. Historian Charlie Hall described the net impact of the technology transfer on the United Kingdom [Hall 2019a, pp. 229–231]:

> [...H]ow much did Britain benefit from the scientific and technological spoils of war? Unfortunately, it is almost impossible to give a definite answer to this question. [...] Some, including Michael Howard who served with T-Force after the war, suspect that the files containing official government valuations have either been destroyed or remain closed to the public. [...]
>
> Turning first to the material spoils, one of the most useful resources which emerged from the British exploitation programme was the collection of BIOS, CIOS, and FIAT Final Reports[...] As we have seen, a government publicity drive brought these reports to the attention of business owners throughout Britain who almost certainly implemented some of the techniques described to increase the efficiency or output of their enterprises—calculating the total value of these improvements would be utterly impossible, but we can be confident that they existed and were fairly widespread. Alongside these reports, BIOS and its related organisations were responsible for the removal of equipment and material too. Under reparations arrangements, Britain received just under 380,000 tons of dismantled German capital equipment[...] A much larger amount of material, most of which would have been far more useful, was taken outside of the official reparations channels and thus remains unaccounted for.
>
> Some material within these removals would have been more valuable than others. For example, under the auspices of Operation Surgeon, some 14,000 tons of aeronautical equipment was removed, including highly specialised wind tunnels and equipment for investigating high-velocity flight at stratospheric altitudes. Much of this went to furnish the new Royal Aircraft Establishment at Farnsborough and would, therefore, have played a direct role in British aeronautical developments moving forward. [...]
>
> It is also worth noting that, from the perspective of British industrial concerns, the greatest benefit of exploitation was not what they gained, but rather what the Germans lost. In short, the damage that exploitation and dismantling wrought to their German rivals allowed them to increase their export capacity at the expense of these German firms. [...]
>
> While the Allies were quick to assert that Germany had lost no more than her leadership in some industries and techniques, many Germans did not agree. [...] Indeed, many of

> these complaints were directed more at the Allied programme of industrial dismantling than at scientific and technological exploitation, though the two schemes ultimately fell under the same broad umbrella. In particular, just as dismantling threatened to severely damage German industry's productive capacity, exploitation was accused of being little more than a 'conveyor belt' for commercial espionage. Both tactics sought to give British business a competitive edge over their renascent German rivals.

As mentioned by Charlie Hall, Michael Howard was an intelligence officer in the British T-Force. In Howard's memoir, he described assisting with the removal of thousands of tons of technology from Germany on a daily or weekly basis, and he speculated on the monetary value of that transferred technology [Howard 2010, pp. 195, 204–205]:

> For ten days we had been victims of the latest false alarm: that everything had to be sent out by the end of the year [1946]. But after ten days of working pretty well night and day, I still had six and a half thousand tons of equipment valued at five million pounds to get out. [...] I never knew who had set that valuation upon the stuff to go, probably its depreciated cost, but it was nowhere near the valuation settled on it in 1948/9. [...]
>
> Coming under fire in some quarters for its very existence, T-Force had a vested interest in putting figures to the results of its work, an extraordinarily difficult and complex calculation. The figure that I mentioned, current by December 1946, might have covered evacuation up to, say, the end of October, but will have referred only to tangibles, i.e. machinery and equipment, upon which it was possible to hang some sort of price-tag, and which were seen as reparations. But what about the intangibles, the intellectual property? A figure produced in 1970 from German sources, for the value of appropriated patents alone, was of the order of £250 million in the coin of post currency-reform (June 1948). On top of these were to be added: 'sharp' battlefield weapons and the means of producing them; industrial processes and the documents and drawings which described them, over the whole field of industry; the knowledge obtained by British scientists and industrialists from their interrogation of their German counterparts and of academics; and access to the records and archives of all of these. I was not shocked or entirely surprised by the figure of £2,000 million quoted privately to me in 1949 by the last remnants of T-Force who had been tasked with making such a valuation (Rufus Harris and Wigg and a handful of others, by now with G Branch, Research Division of the CCG).

Even Howard's descriptions and estimates were only a fraction of the total technology transfer to the British. They did not include transfers that were carried out by organizations other than T-Force, such as the Royal Navy and specific British companies. Moreover, they did not include British exploitation of Austria, or of German technology that the British discovered in formerly German-controlled territory such as France and Norway. They also did not assign a monetary value to the more than 1,000 German-speaking scientists who worked for the United Kingdom after the war. With all of those factors in mind, the total technology transfer to the British was probably quite comparable to that to the United States.

The impacts of the technology transfer on the Soviet Union and France were presumably at least as large as those on the United States and United Kingdom.

John Gimbel quoted the best available estimates of the financial value of the technology transfer to the United States [Gimbel 1990a, p. 152]:

> ...It is perhaps fitting to refer briefly to the discussion of value contained in a manuscript on the history of FIAT, which may be found in the archives records of the OMGUS Historical Office. After commenting that the Russian figure of $10 billion announced by Molotov at the Moscow CFM was too high, the unnamed authors argued that only in time—after tests, trials, and applications—could a precise value be established. Nevertheless the authors "estimated that FIAT activities should save the government and industry in the United States at least five billion dollars." If we were to accept this as a fair global figure, and if we were to make the altogether reasonable assumption that the British received value roughly equal to that of the United States, it would follow that Molotov at the Moscow CFM was right on the button.

Donald Putt and Senator Harry Byrd gave a similar estimate of billions of dollars for the United States (pp. 5492–5495). Considering that these estimates were lower bounds and that the French and especially the staggering Soviet removals were not included, the total value of technologies transferred out of the German-speaking world after the war almost certainly exceeded 20 billion 1940s-era U.S. dollars.

There are at least four factors that were not considered in the above financial estimates, and that could increase the true total value of technologies that were transferred out of the German-speaking world potentially by orders of magnitude beyond the lower bound of 20 billion 1940s-era U.S. dollars:

1. Some of the most valuable technologies that were transferred were either secret or at least not widely known during and immediately after the war, and the historical facts that they were in fact transferred and not spontaneously invented in postwar Allied countries remain classified, buried, or ignored to this day. Examples include oral contraceptives and other advanced pharmaceuticals (p. 354), fuel-air explosives (p. 557), advanced materials (Section 3.8), stealth technology (p. 1234), biotechnology (Section A.1), biological weapons (Section A.3), chemical weapons up through advanced V-series nerve agents (Section A.4), transistors (Section B.1), printed circuits (Section B.2), integrated circuits (Section B.3), light emitting diodes (Section B.4), lasers (Section C.3) and other directed energy technologies (Appendix C), advanced fission bombs (Sections D.14 and D.15.5), hydrogen bombs (Sections D.9 and D.14), intercontinental jets (Section E.1), intercontinental rockets (Section E.2), space planes (Section E.3), submarine-launched and advanced solid propellant rockets (Section E.4), and many others. Because the details of their transfer were obscured, all of these advanced technologies were not included in the earlier financial estimates, yet they certainly should be.

2. The true value of the transfer must reflect what it would cost to fully nullify the transfer now. Obviously this situation is purely hypothetical, yet it is useful nonetheless for calculating the financial value in modern terms. If other countries were to fully repay Germany and Austria now for the cost of all the creators, creations, materials, and services that were transferred in the 1940s, they would need to repay not the original number of 1940s-era dollars (whatever that number may be), but rather the far larger number of modern dollars that would be equivalent, taking inflation into account. Moreover, if the transfer were considered a loan like any other financial transaction, countries would also owe Germany and Austria the interest on that transferred amount that had accumulated and compounded at fair-market rates from the 1940s to the current day.

3. The total value of the German-speaking creators and creations that were transferred must also take into account their true value to the countries that received them, from World War II through the present. The transferred creators and creations formed the basis of whole industries in biotechnology, pharmaceuticals, chemicals and materials, microelectronics and electronic devices, energy, aerospace, and other areas. They provided all types of weapons of mass destruction (biological, chemical, and nuclear), all methods to deliver them (intercontinental jet bombers, cruise missiles, intercontinental ballistic missiles, and submarine-launched missiles), and all of the technologies for modern conventional warfare as well. Therefore, transferred creators and creations allowed certain countries to greatly prosper or even become dominant throughout all the years since the war. What value could one place on the resulting success of those national economies and militaries over all the postwar decades?

4. Likewise, the total value of the German-speaking creators and creations that were transferred must consider the true value of their loss for Germany and Austria. If Germany and Austria—instead of other countries—had had the benefit of all of those creators and creations during all of the postwar decades, what would have been the resulting success of their national economies?

Although one might be tempted to cite the Marshall Plan as an example of money being given back to Germany and Austria, the United States provided less than \$2 billion total to West Germany and Austria under the Marshall Plan, and most of that was simply loans that had to be fully repaid to the United States within a certain period of time [Schain 2001]. Thus Germany and Austria essentially fully funded their own postwar reconstruction and rebirth, in addition to shouldering much of the burden of postwar industrial and scientific development in the United States, United Kingdom, France, Soviet Union, and other countries.

It is possible that all of the countries involved might agree that the true total value of the technology transfer was an appropriate amount for reparations, but at the very least, the true value should be properly calculated, publicly acknowledged, and clearly stated in the history books.[9]

---

[9] Just to avoid any misunderstandings, I do not at all mean to disregard or minimize any of the other ethical issues, atrocities, injustices, casualties, losses, and unfortunate effects that were associated with the war, and that have been so thoroughly documented and discussed elsewhere. Rather, I am endeavoring to shed light on this additional issue that has not received much scrutiny to date, and that should be considered along with all of the others. Even more importantly, I would like to emphasize the enormous long-term economic and societal benefits that can be generated if countries fully fund and properly support revolutionary innovators and revolutionary innovations, as demonstrated by these historical examples.

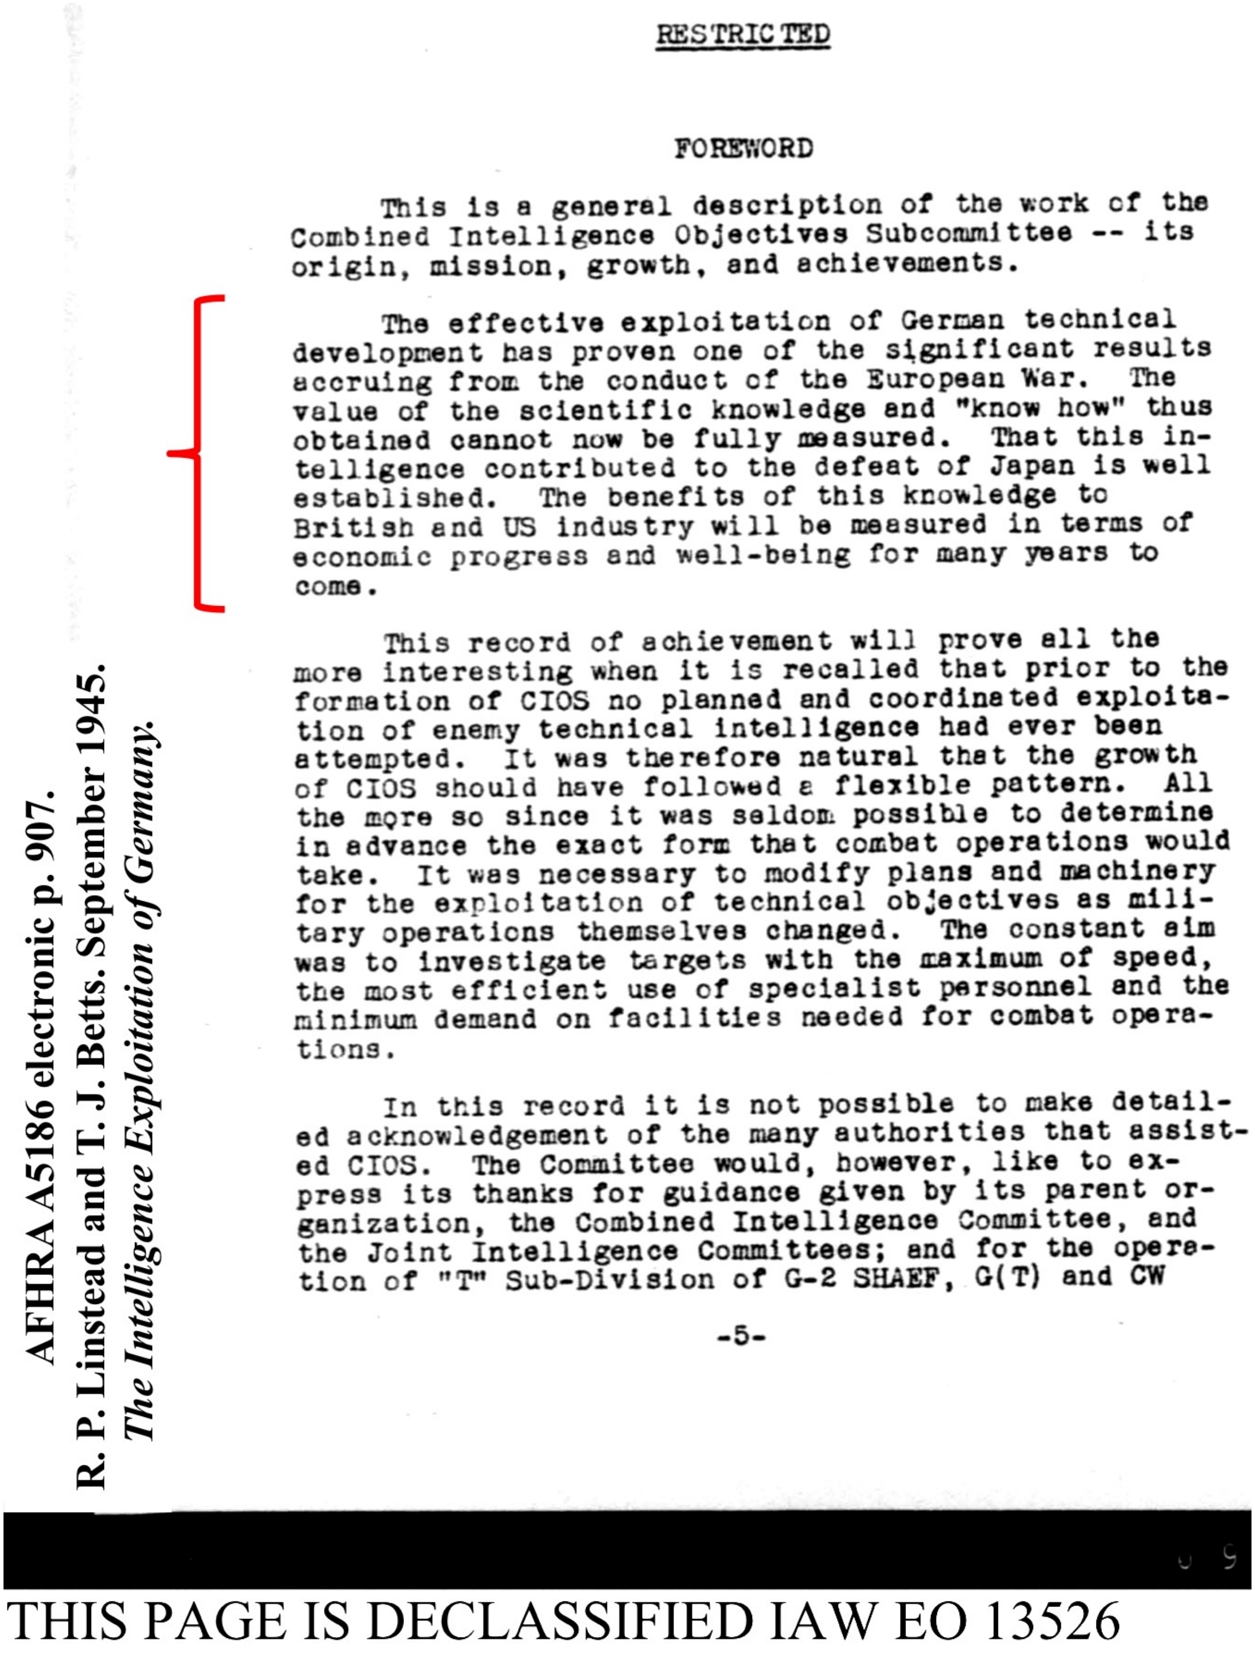
For reasons of length, this study cannot even begin to address the large number of other ethical questions that are already covered so well and in so much detail by many other authors; I highly recommend that all readers seek out those books and study them. See for example: Bar-Zohar 1967; Beyerchen 1977; Black 2012a, 2012b, 2017; Borkin 1978; Bower 1987; Campbell and Harsch 2013; Cornwell 2003; Crim 2018; Deichmann 1996; Joseph Fisher 2017; Friedrich et al. 2017; Geissler 1998a, 1998b, 1999; Gellermann 1986; Georg 2012; Gimbel 1986, 1990a, 1990b, 1990c; Gröhler 1989; Guillemin 2005; Friedrich Hansen 1993; István Hargittai 2006; Harris Paxman 2002; Haunschmied et al. 2007; Hayes 2001; Heim et al. 2009; Hentschel and Hentschel 1996; Linda Hunt 1991; Jacobsen 2014; Jeffreys 2008; Karlsch and Laufer 2002; Kaszeta 2020; Kater 1989; Keynes 2019; Klee 2001; Kurowski 1982; Lasby 1971; Leff 2019; Le Maner and Sellier 2001; Julian Lewis 2002; Lichtblau 2014; Macrakis 1993; Milton Mayer 2017; Medawar and Pyke 2000; Mick 2000; Nachmansohn 1979; Nash 2013; Michael Neufeld 1995, 2002, 2003, 2007; Plumpe 1990; Posner and Ware 2000; Pringle 2006; Renneberg and Walker 1993; Sasuly 1947; Schambach 2011; Sellier 2003; Simpson 1988; Spitz 2005; Stoltzenberg 1994, 2005; Sutton 1976; Szöllösi-Janze 2001, 2015; Tucker 2006; Wachsmann 2015; Bernd Wagner 2000; Jens-Christian Wagner 2011, 2015; Wallace 2004; Whitman 2018.

For reference, the total amount that the United States spent on its own R&D programs (including the Manhattan Project, radar, penicillin, etc.) throughout all of World War II was only approximately 3 billion 1940s-era dollars. The United Kingdom spent much less, and other Allied countries spent relatively little on R&D. For the R&D that the United States and other countries acquired from the German-speaking world, even the lower-bound $20 billion estimate is nearly one order of magnitude larger than the U.S. R&D. Including the other factors listed above, the transferred R&D may well have had a total financial value several orders of magnitude greater than the endogenous R&D.

Thus whether one considers the number of truly revolutionary scientific innovators, the number of revolutionary scientific innovations (Chapter 2–9 and Appendices A–E), or the financial value of the innovators and innovations, the amount of science and technology that was transferred out of the German-speaking world appears to absolutely dwarf the amount that was "home grown" within the other countries. Perhaps the only thing more remarkable than this technology transfer is how nearly it has been forgotten by the modern world.

Charlie Hall gave an impassioned plea for the massive technology transfer from the German-speaking world to be much more widely studied and far more prominently featured in history books [Hall 2019a, p. 238]:

> This wholesale removal of a defeated nation's scientific and technological resources, including recruitment of expert personnel, by its military conquerors, has no parallel in modern history and deserves greater scrutiny. There is, without doubt, more to be said about the exploitation schemes of all four occupying powers, as well as about the involvement of other nations, including those whose participation in the Second World War was peripheral at best. [...] It would be excellent to see exploitation feature more prominently in histories of the military-industrial complex, of scientific intelligence, of post-1945 arms races, of transnational transfers of technology and expertise and of the Second World War and Cold War more generally. This would hopefully lead to a stronger presence for the programme in the public consciousness and would ensure that never again could it be described as a 'forgotten history.'



RESTRICTED

FOREWORD

This is a general description of the work of the Combined Intelligence Objectives Subcommittee -- its origin, mission, growth, and achievements.

The effective exploitation of German technical development has proven one of the significant results accruing from the conduct of the European War. The value of the scientific knowledge and "know how" thus obtained cannot now be fully measured. That this intelligence contributed to the defeat of Japan is well established. The benefits of this knowledge to British and US industry will be measured in terms of economic progress and well-being for many years to come.

This record of achievement will prove all the more interesting when it is recalled that prior to the formation of CIOS no planned and coordinated exploitation of enemy technical intelligence had ever been attempted. It was therefore natural that the growth of CIOS should have followed a flexible pattern. All the more so since it was seldom possible to determine in advance the exact form that combat operations would take. It was necessary to modify plans and machinery for the exploitation of technical objectives as military operations themselves changed. The constant aim was to investigate targets with the maximum of speed, the most efficient use of specialist personnel and the minimum demand on facilities needed for combat operations.

In this record it is not possible to make detailed acknowledgement of the many authorities that assisted CIOS. The Committee would, however, like to express its thanks for guidance given by its parent organization, the Combined Intelligence Committee, and the Joint Intelligence Committees; and for the operation of "T" Sub-Division of G-2 SHAEF, G(T) and CW

EXPLOITATION OF GERMANY FOR TECHNOLOGICAL AND SCIENTIFIC INFORMATION

After World War I there was no real attempt by the victors to exploit Germany for technical and scientific knowledge. However, long before World War II with Germany had ended, plans were made by the Joint Chiefs of Staff for the complete exploitation of Germany for technical information.

In accordance with these plans, the government is now engaged in exploiting Germany for all the technical and scientific information that can be obtained. Exploitation has involved the sending of several hundred highly qualified American technicians and scientists into Germany close upon the heels of our conquering armies. These investigators have examined manufacturing plants and equipment, records and documents and have interrogated German personnel. The information of industrial value that has been collected is being made available to the public by the Department of Commerce.

Steps are now being taken to extend this exploitation by bringing the best German scientists and technicians to this country so that their talents can be used here.

Several governmental agencies are involved in the technical exploitation of Germany program in addition to the Department of Commerce. These are the War and Navy Departments, the Department of the Interior, and the Department of Agriculture. The State Department is establishing several consulates in the American zone for the purpose of issuing visas under the President's program for limited immigration quotas.

Many of the German scientists and technicians will be brought over here for exploitation by the Navy and War Departments in connection with weapon developments

for reasons of national security. These agencies already have about one hundred and fifty German scientists and technicians in this country. However, these were brought here without their families with the intention of returning them to Germany within six months to a year.

Other German scientists and technicians will be brought to the U. S. for exploitation for civil purposes, primarily for American industry. As these will only be brought over after it has been definitely determined to be for the national interest, they will be exploited on an unrestricted basis rather than being employed by certain firms. This exploitation for non-military purposes will be sponsored by the appropriate Federal agency or department.

The number of German scientists to be brought to American for exploitation will be strictly limited. Present estimates are that the total number will not exceed three hundred, limited to those who can make positive valuable contributions to our national welfare. They will include the best of the pure scientists, those comparable to Prof. Einstein. In the past, the United States has depended to a considerable extent upon German scientists for pure basic scientific research. Such research forms the basis for practical developments. They will also include eminent physicists, outstanding chemists, Nobel prize winners and leaders in various research and development fields.

The exploitation of these highly trained Germans will be of great value in the development of new types of weapons which were being planned by the Germans as the war ended. It will also be in the national interests to use them to increase our production potential in many industrial fields. Due to our dwindling natural resources, it has become a strategical necessity that our nation develope substitute and synthetic materials.

~~RESTRICTED~~ SECRET

Great Britain, France and Russia have recognized the value of exploiting German expert personnel and it is quite probable that such neutrals as Sweden, Switzerland and Spain will encourage immigration of German scientists and technical experts as soon as Germans are allowed to immigrate to such countries. The ban on certain war industries and other war-supporting industries like aluminum, synthetic oil, synthetic rubber, and ball-bearings will cause the highly skilled German technicians in these industries to seek employment in other countries and thus aid such countries in increasing their war potential.

However, it is now well known that after the last war and because of the disarmament provisions of the Versailles Treaty, the German government arranged for many technicians to be employed in countries like Sweden, Russia, Switzerland and Spain in war production industries. Then when German rearmament began these technicians were called back to Germany.

With this knowledge in mind, adequate provisions and safeguards will be made to protect our secrets.

Those to be brought over will be carefully screened so that no active Nazis are included. Also those that are selected will be brought to the U.S. only if they volunteer. An honest desire to become U.S. citizens and never return to Germany will also be a consideration in selecting the individuals.

Only the immediate members of the families of those scientists who intend to live in this country will be brought over. The members of the families will be checked as to Nazi sympathies as some German youths were among the most rabid Nazis.

In view of the small number of families that will come, the effect on the housing situation will be very slight. It may well be that movement of families may have to be postponed until housing is available in each particular case. Movement

of families may also be delayed during a probationary period which may be necessary to determine accurately the German scientist's cooperativeness and the honesty of his desire to become a good American citizen.

It will be the government's policy that these Germans are exploited in behalf of the whole nation and not for or by single private interests. In some cases arrangements will be made with industrial associations or societies for exploitation so that all those engaged in a particular industry may profit on an equal basis. Any resulting patents must be freely licensed on a reasonable royalty basis.

Closely related to the exploitation of German scientists and technicians is the government program for exploitation of German developments in industrial machinery, tools, equipment and materials. Samples of these are being procured through reparations procedures for shipment to the United States where they are made available for study by American industry on a non-restrictive open-to-the-public basis.

From the above, it is evident that the government is using vacuum cleaner methods to acquire all the technical and scientific information that the Germans have. The value of this information to the United States will probably far exceed any cash reparations.

Information on the industrial aspects of the exploitation program may be obtained from the Office of the Publication Board Department of Commerce.

PROPOSAL FOR A COMPENDIUM OF GERMAN WAR TIME TECHNOLOGY

Introduction

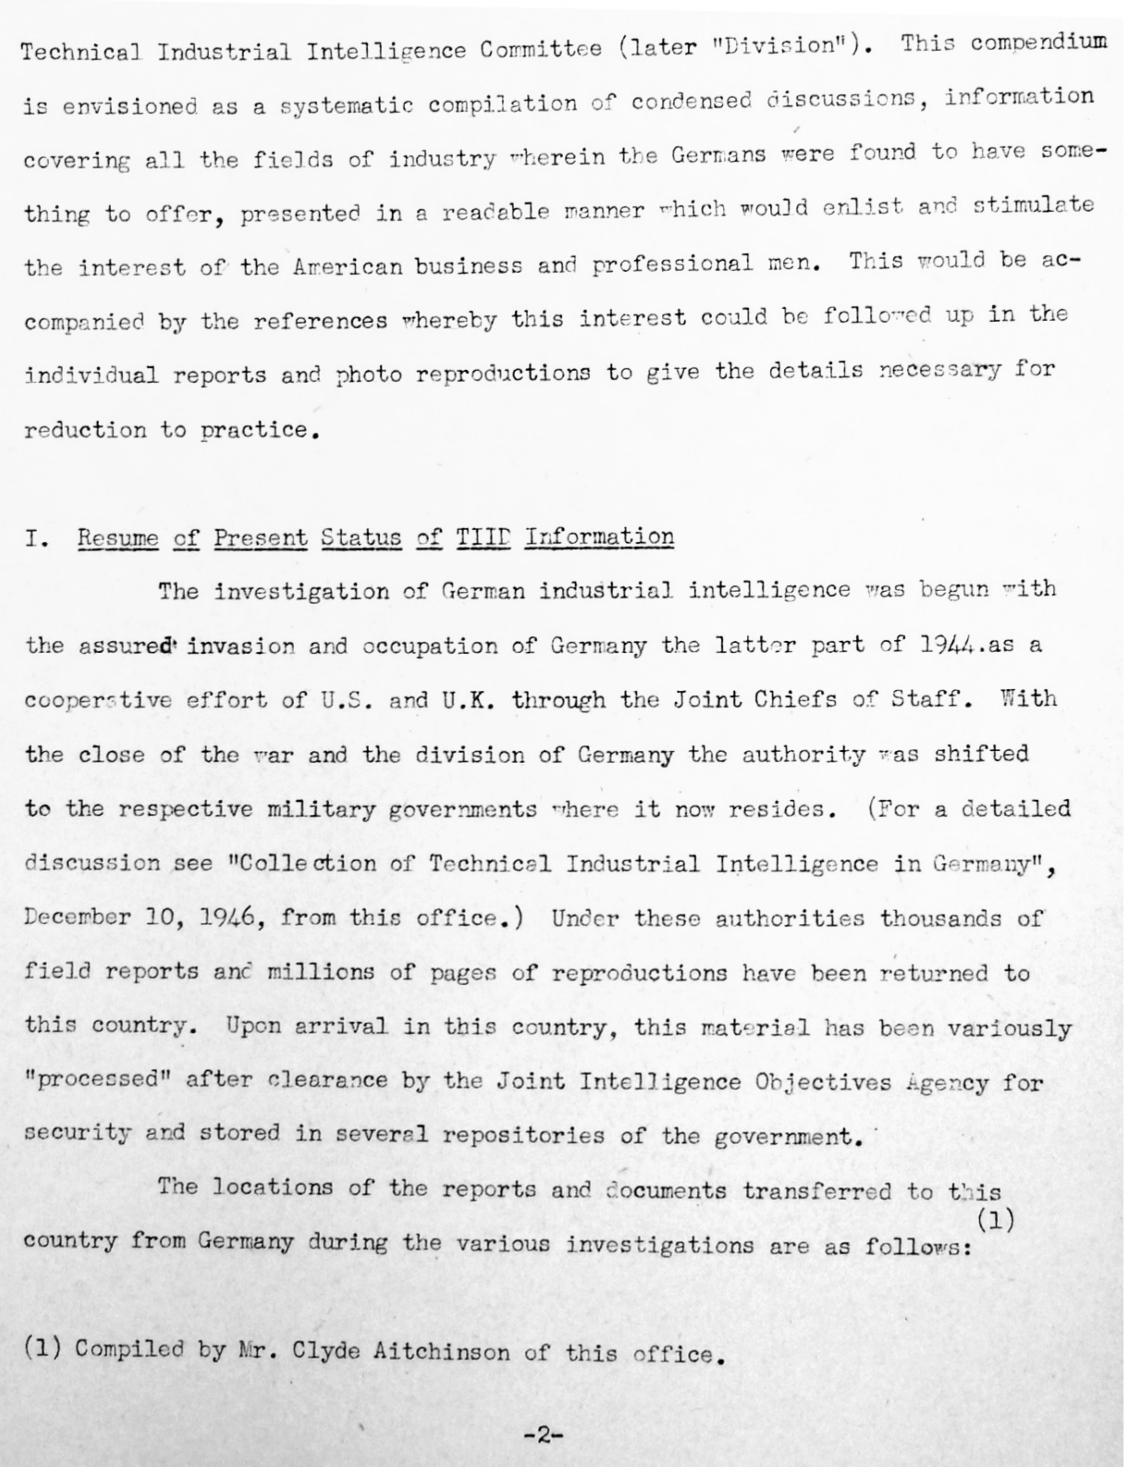
The accumulation of the technical industrial information, which has resulted from the detailed investigations of the German industry for the past two years by this office, has reached such enormous proportions that it has become difficult to inform the public of the possible benefits available to it. This accumulation of information not only represents the greatest transfer of mass intelligence ever made from one country to another, but it also represents one of the most valuable acquisitions ever made by this country. The problem becomes, therefore, to make the contents of this acquisition fully known to the public. Although a few high lights have been brought to public attention by general press notices, it is obvious that this means is not practicable for more than an infinitesimal amount of the available information. It is equally obvious that the complete accumulation now available through the Publication Office cannot be so publicized. A few organizations which have professional library research workers for the purpose have followed the details from the beginning with great benefit. However, the general public does not know of the availability of this information largely because the average man does not realize it may contain material in which he is vitally interested.

Now that the end of the collection program is in sight, it is proposed to set up a plan whereby all this information can be correlated, evaluated and condensed for publication in a permanent form suitable for the use of the average business man. Specifically, such a publication would take the form of a compendium of the German industrial information obtained in Germany by the

Figure 11.48: L. B. Kilgore. 10 January 1947. Proposal for a Compendium of German War Time Technology, Draft No. 2 [NARA RG 40, Entry UD-75, Box 3, Folder Inter-Office Memoranda: To and From Robert Reiss].

DECLASSIFIED
Authority NND968018

NARA RG 40, Entry UD-75, Box 3, Folder Inter-Office Memoranda: To and From Robert Reiss



Technical Industrial Intelligence Committee (later "Division"). This compendium is envisioned as a systematic compilation of condensed discussions, information covering all the fields of industry wherein the Germans were found to have something to offer, presented in a readable manner which would enlist and stimulate the interest of the American business and professional men. This would be accompanied by the references whereby this interest could be followed up in the individual reports and photo reproductions to give the details necessary for reduction to practice.

I. Resume of Present Status of TIID Information

The investigation of German industrial intelligence was begun with the assured invasion and occupation of Germany the latter part of 1944.as a cooperative effort of U.S. and U.K. through the Joint Chiefs of Staff. With the close of the war and the division of Germany the authority was shifted to the respective military governments where it now resides. (For a detailed discussion see "Collection of Technical Industrial Intelligence in Germany", December 10, 1946, from this office.) Under these authorities thousands of field reports and millions of pages of reproductions have been returned to this country. Upon arrival in this country, this material has been variously "processed" after clearance by the Joint Intelligence Objectives Agency for security and stored in several repositories of the government.

The locations of the reports and documents transferred to this country from Germany during the various investigations are as follows:(1)

(1) Compiled by Mr. Clyde Aitchinson of this office.

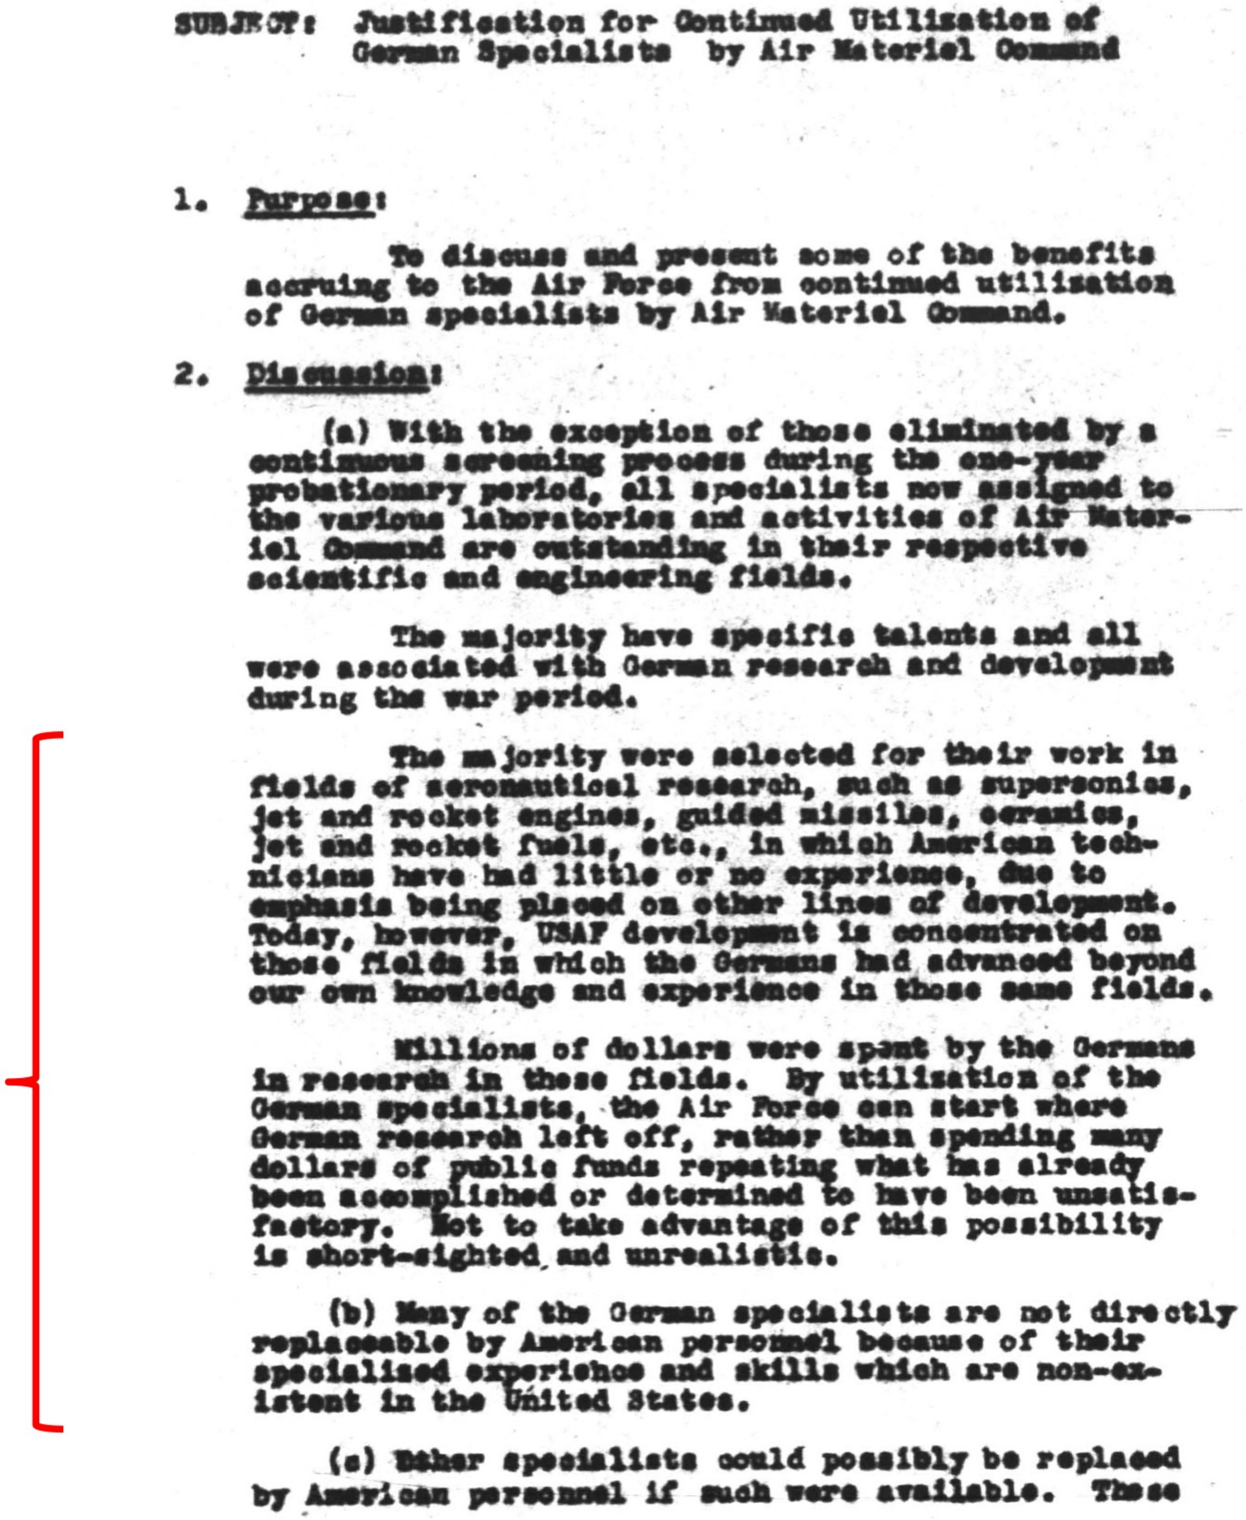
AFHRA A2056 electronic p. 405.
Donald Putt to Joseph McNarney. 10 December 1947.
German Specialist Program at the Air Materiel Command. Tab F.



SUBJECT: Justification for Continued Utilization of German Specialists by Air Materiel Command

1. Purpose:

To discuss and present some of the benefits accruing to the Air Force from continued utilization of German specialists by Air Materiel Command.

2. Discussion:

(a) With the exception of those eliminated by a continuous screening process during the one-year probationary period, all specialists now assigned to the various laboratories and activities of Air Materiel Command are outstanding in their respective scientific and engineering fields.

The majority have specific talents and all were associated with German research and development during the war period.

The majority were selected for their work in fields of aeronautical research, such as supersonics, jet and rocket engines, guided missiles, ceramics, jet and rocket fuels, etc., in which American technicians have had little or no experience, due to emphasis being placed on other lines of development. Today, however, USAF development is concentrated on those fields in which the Germans had advanced beyond our own knowledge and experience in those same fields.

Millions of dollars were spent by the Germans in research in these fields. By utilization of the German specialists, the Air Force can start where German research left off, rather than spending many dollars of public funds repeating what has already been accomplished or determined to have been unsatisfactory. Not to take advantage of this possibility is short-sighted and unrealistic.

(b) Many of the German specialists are not directly replaceable by American personnel because of their specialized experience and skills which are non-existent in the United States.

(c) Other specialists could possibly be replaced by American personnel if such were available. These

Figure 11.51: Donald Putt to Joseph McNarney. 10 December 1947. German Specialist Program at the Air Materiel Command, Tab F [AFHRA A2056 electronic p. 405].

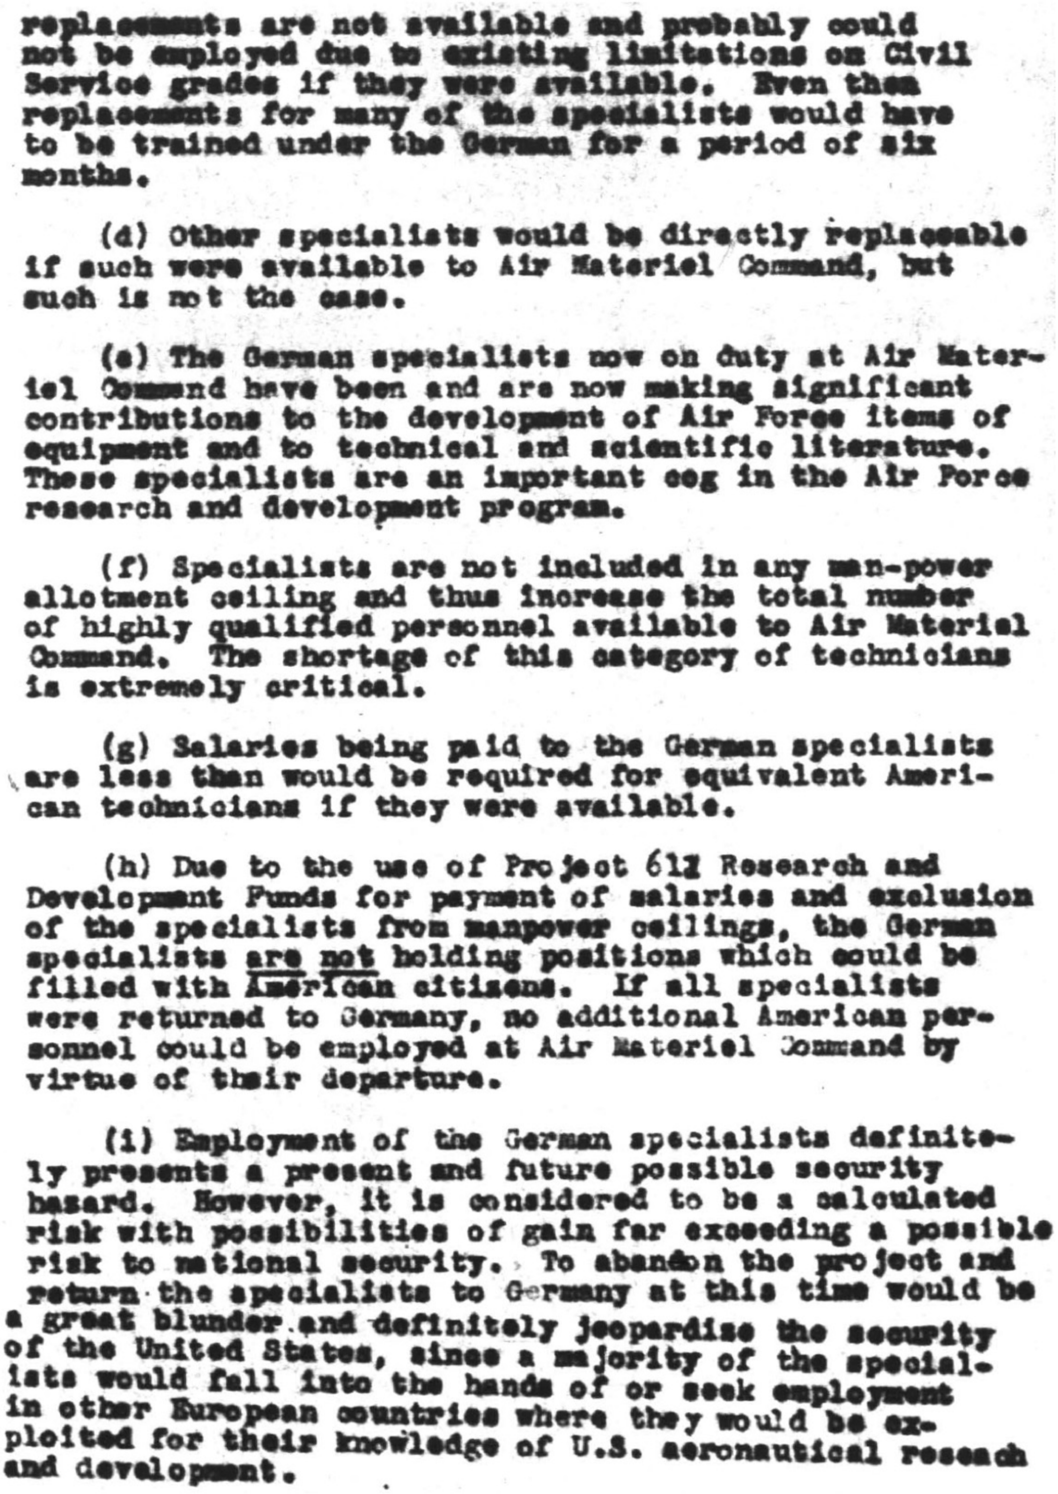
Donald Putt to Joseph McNarney. 10 December 1947.
German Specialist Program at the Air Materiel Command. Tab F.



replacements are not available and probably could not be employed due to existing limitations on Civil Service grades if they were available. Even then replacements for many of the specialists would have to be trained under the German for a period of six months.

(d) Other specialists would be directly replaceable if such were available to Air Materiel Command, but such is not the case.

(e) The German specialists now on duty at Air Materiel Command have been and are now making significant contributions to the development of Air Force items of equipment and to technical and scientific literature. These specialists are an important cog in the Air Force research and development program.

(f) Specialists are not included in any man-power allotment ceiling and thus increase the total number of highly qualified personnel available to Air Materiel Command. The shortage of this category of technicians is extremely critical.

(g) Salaries being paid to the German specialists are less than would be required for equivalent American technicians if they were available.

(h) Due to the use of Project 612 Research and Development Funds for payment of salaries and exclusion of the specialists from manpower ceilings, the German specialists are not holding positions which could be filled with American citizens. If all specialists were returned to Germany, no additional American personnel could be employed at Air Materiel Command by virtue of their departure.

(i) Employment of the German specialists definitely presents a present and future possible security hazard. However, it is considered to be a calculated risk with possibilities of gain far exceeding a possible risk to national security. To abandon the project and return the specialists to Germany at this time would be a great blunder and definitely jeopardize the security of the United States, since a majority of the specialists would fall into the hands of or seek employment in other European countries where they would be exploited for their knowledge of U.S. aeronautical reseach and development.

Figure 11.52: Official U.S. government policy was to underpay German-speaking scientists for their work. Donald Putt to Joseph McNarney. 10 December 1947. German Specialist Program at the Air Materiel Command, Tab F [AFHRA A2056 electronic p. 406].

SUBJECT Distribution of German Scientists' Reports.

TO TSDIN FROM TSNFE DATE 29 July '46 COMMENT NO. 1.

Colonel Putt

1. In an attempt to attain wider distribution for the reports written by German scientists, these reports are being re-edited and published IN the form of T-2 Technical Reports, and will be sent to companies and organizations whose representatives have interrogated German scientists, and to those who it is felt have an interest in the work of the scientists. These reports will be sent only to the companies and organizations who have signed the secrecy agreement.

2. Acting on recommendations contained in the letter from JIOA dated 9 May, 1946, reports will be classified "Confidential" but all reference to German scientist's name and his background will be put on one page of the report with a note that upon removal of that page, the remainder of the document may be down-graded from "Confidential" to "Restricted", unless, of course, the subject matter in itself has a classification higher than restricted.

3. Unless otherwise directed by Deputy Commanding General of Intelligence T-2, this office will proceed with distribution of T-2 Technical Reports by German scientists as outlined above.

AFHRA A2055 Frame 1177

13. The Alien Property Custodian must consult the Secretary of State before vesting title in himself to a patent application. Executive Order 9193, supra.

14. Legal title to a patent is assignable by an instrument in writing, recordable in the United States Patent Office. U.S. Code, title 35, sec. 47.

15. The courts are not agreed that legal title to a patent will re-vest in an assignor merely upon the occurrence of a named event and without a reassignment in writing.

16. The German scientists are not anxious to cooperate with Government personnel in disclosing possibly patentable inventions known to them prior to their entry into the United States while the title is likely to be vested by the Alien Property Custodian; but are desirous of cooperating in such disclosures if the United States takes the title even though the title may not be reassigned for some years and possibly never, depending on the nature of the invention.

CONCLUSIONS

17. It is concluded that:

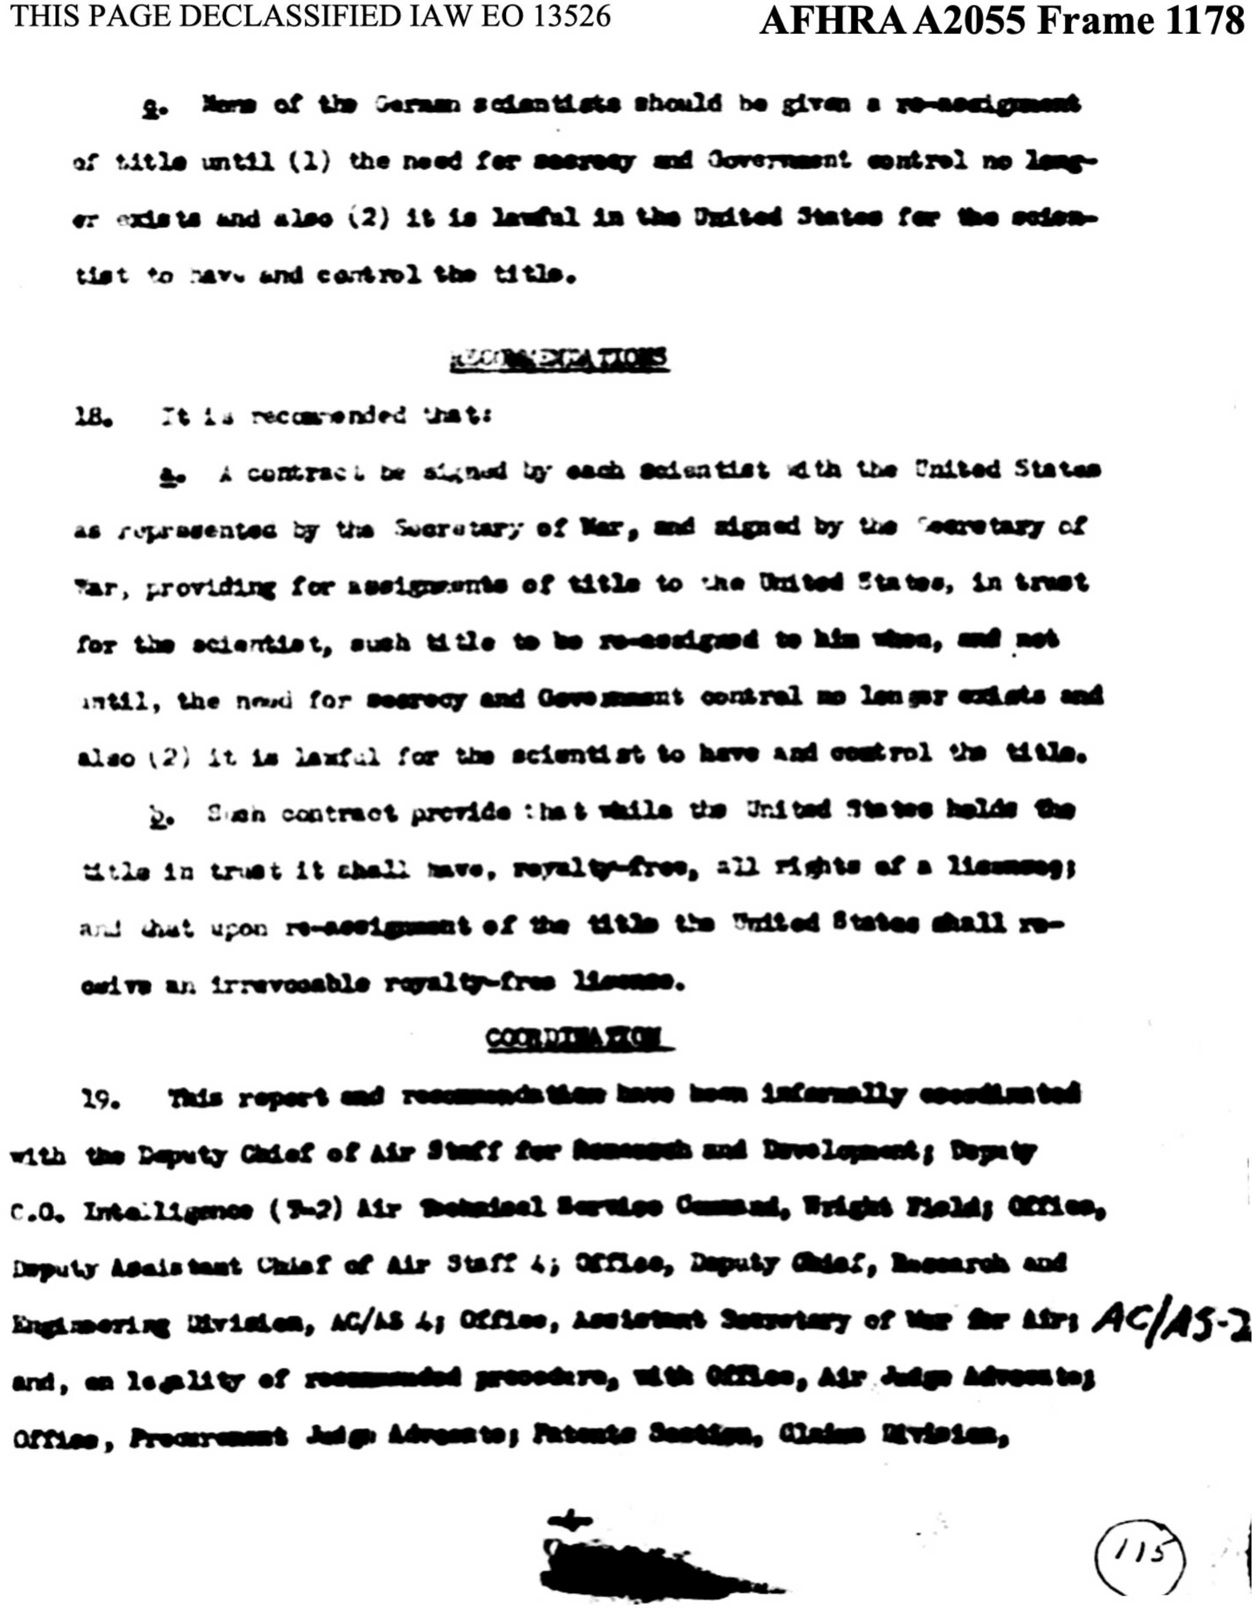
a. The United States should take title to such inventions as are disclosed by the German Scientists now employed under Project Overcast where the invention requires secrecy and is important to the armament or defense of the United States.

b. Patent applications on such inventions should be prepared and filed by Government personnel now assigned to similar work.

[redacted]

115

Figure 11.54: Official U.S. government policy was to deny German-speaking scientists ownership of their inventions, or in some cases even to be named as the inventor of that technology. Joseph W. Hazell. 28 February 1946. Project Overcast [AFHRA A2055 Frame 1177].



THIS PAGE DECLASSIFIED IAW EO 13526

AFHRA A2055 Frame 1178

g. None of the German scientists should be given a re-assignment of title until (1) the need for secrecy and Government control no longer exists and also (2) it is lawful in the United States for the scientist to have and control the title.

RECOMMENDATIONS

18. It is recommended that:

a. A contract be signed by each scientist with the United States as represented by the Secretary of War, and signed by the Secretary of War, providing for assignments of title to the United States, in trust for the scientist, such title to be re-assigned to him when, and not until, the need for secrecy and Government control no longer exists and also (2) it is lawful for the scientist to have and control the title.

b. Such contract provide that while the United States holds the title in trust it shall have, royalty-free, all rights of a licensee; and that upon re-assignment of the title the United States shall receive an irrevocable royalty-free license.

COORDINATION

19. This report and recommendation have been informally coordinated with the Deputy Chief of Air Staff for Research and Development; Deputy C.O. Intelligence (T-2) Air Technical Service Command, Wright Field; Office, Deputy Assistant Chief of Air Staff 4; Office, Deputy Chief, Research and Engineering Division, AC/AS 4; Office, Assistant Secretary of War for Air; AC/AS-2 and, on legality of recommended procedure, with Office, Air Judge Advocate; Office, Procurement Judge Advocate; Patents Section, Claims Division,

4

> Believe this development would be important for Pacific War. . . . The research directors and staff realize impossibility for continuation of rocket development in Germany. . . . They are anxious to carry on their research in whatever country will give them the opportunity, preferably United States, second England, third France.

(9-A)

Excerpt from letter is as follows:

> Dr. von Karman estimates that here at this one place there is information immediately available that would take us at least two years of research in the U.S. to obtain. Also enough here to expedite our jet engine development program by six to nine months.

(5-A)

Recommendations to the Commanding General, U. S. Strategic Air Forces in Europe (Lt. Gen. Carl Spaatz), from his Deputy (Maj. Gen. H. J. Knerr) included the comment, "Occupation of German scientific and industrial establishments has revealed the fact that we have been alarmingly backward in many fields of research. If we do not take this opportunity to seize the apparatus and the brains that developed it and put the combination back to work promptly, we will remain several years behind while we attempt to cover a field already exploited." In addition, it was suggested that immediate dependent families be allowed to accompany the scientists, a move considered essential in view of the political and economic factors involved in their general uprooting. As these and other communications indicate, it was believed urgent that immediate action be taken to transport scientists to the United States without delay. The motivating reason was to insure the employment of those top-ranking scientists who were without question the

Chapter IX

THE COMMAND AND PROJECT "PAPERCLIP"

The Need

World War II had proven that Germany was many years ahead of the United States in a number of scientific and technical fields, notably in propulsion, jet and rocket engines, jet fuels, and guided missiles.[1] While extensive know-how in these scientific areas was in the possession of many outstanding scientists and engineers living in Occupied Germany and the U.S. Zone of Austria, within the United States itself there was a particular shortage of knowledge. In the period immediately following that global conflict, some of these same fields received considerable attention in the United States Air Force's research and development effort. Consequently, from 1945 onward there was an ever-growing shortage of scientific and professional manpower, a situation even more obvious in the agencies of the national government. To meet these scientific needs, Project "Paperclip" was born.

Project "Paperclip" Defined

From the time the Air Research and Development Command became operational in April 1951 this project was active at the level of the Joint Chiefs of Staff. It was concerned with the immigration

scientists departed from Europe between 11-13 September 1945. One week later, they arrived in Boston and were on their way to Wright Field. Project "Overcast" was in full swing.[11]

Army Air Force interest in using these German scientists and technicians had become active during the very early stages of Germany's collapse. Equipment of intelligence value, captured during the months preceding V-E Day, was to be shipped from abroad to Wright Field for evaluation and study. This exploitation program had been coordinated with the British Chiefs of Staff who were to share in its results. Obviously, it would not only be advantageous but also "a measure of necessity" to export experienced German technicians to America along with the equipment. Colonel Donald L. Putt, leading the Air Force Intelligence teams that took over these German research laboratories and experimental stations, made this evaluation:[12]

> I visited a great many of them . . . . Their research progress in jet and rocket propulsion, aerodynamics, thermodynamics, supersonics, and other fields was clearly far ahead of anything of the kind we had done.

From this consideration grew the realization by American military leaders of the exploitation value of the German military research and development program, particularly in the weapons fields, in prosecuting an all-out war against Japan. The program also served to snatch away certain researchers from the Soviet

Under the title: “How the USA and England get reparations from Germany”, D. Melnikov writes in the Moscow weekly “New Era,” the latest one to arrive here, among other things:

Neither England nor the USA has yet declared their reparations claims to Germany. However, they have already obtained goods from Germany that significantly exceed the amount of 10 billion dollars.

As Colonel Wilkinson, the head of the industrial department of the American military government in Germany, announced, at the end of last year a number of companies in the western zones were made available as advance payments for the reparation account. However, when the dismantling of these factories began, the Allied authorities used all possible means to stop the shipment of machinery and equipment to the Soviet Union, while the removal of the unique equipment intended for England and the USA was carried out at a rapid pace. The most important companies in the American occupation zone were dismantled. All nickel works, 90% of the aircraft engine factories, 70% of the motorcycle engine factories, a significant (part) of the municipal businesses, the machine tool factories, etc. were exported, etc.

This is the official dismantling program. However, the confiscation of industrial equipment by England and the USA goes far beyond this program, as can be seen even from the sparse press reports. The Anglo-Saxon countries mainly cover their reparations claims through so-called “invisible reparations,” which not only include machinery, but also the industrial products that are continually manufactured. We would like to give some examples.

According to a Reuters report, machines of the latest models from ongoing production at the Fritz Müller works in Ober-Eßlingen were shipped to England in the second half of 1946. At the beginning of January 1947, a significant number of machines were again sent to a number of larger English companies, including numerous unique sample and test machines. At the end of last year, the English authorities confiscated almost the entire finished production of the Siemens-Schuckert-Werke in Müllheim, which produces turbines and turbine components, and transported them to England. In the second half of 1946, as the “Berliner Zeitung” dated 21 January this year reported that 300,000 tons of wood worth 1.5 pounds sterling were shipped from Germany to England. The English military government even has control over all the products from the 20 fountain pen factories in the English occupied zone.

Industrial products are also confiscated in the American zone. According to the orders of the American occupation authorities, over 12,000 tons of aluminum were collected here, melted down and shipped to the USA. The occupation authorities have access to 95 percent of all cameras manufactured by the well-known Munich Agfa factories. End of November last year, the Directorate of the State Council of the American Zone turned to the military government with a request to cancel an order to the shoe factories for the delivery of 245,000 pairs of shoes. Consequently, such deliveries must have taken place.

Another category of reparations that England and the USA receive from Germany are German patents and inventions. The occupation authorities of the western zones have placed their hands on approximately 200,000 patents. At the end of last year, a reporter for the “News Chronicle” managed to gain insight into the report of an Anglo-American special commission that investigated the possibility of exploiting German inventions. The rapporteur places a very high value on the practical value of these inventions. An American manufacturer offered the US government $20 million for the use of a single production process patented in Germany.

Furthermore, England and the USA confiscated the largest part of the German gold reserve, amounting to 160–170 tons, which had been brought to the West by the Hitlerite fascists before the end of the war and was mainly concentrated in the American zone of occupation. In addition, the Swiss government has agreed to hand over the 50 tons of German gold in their country to England and the USA, and the Swedish government has agreed to hand over 7 tons. This means that over 200 tons of German gold are already in the hands of England and the USA. It should also be added that the British and American occupation authorities confiscated an enormous amount of valuables.

Ultimately, the USA, England including the Dominions and France received 470,000 GRT from the German merchant fleet.

The above shows how many reparations the Anglo-Saxon states have already secured within Germany, and yet this information does not yet provide a complete picture. England and the USA have received the extensive German foreign assets in the so-called neutral states as well as in the USA, in England, in Latin American and other countries.

The Berlin newspaper "Die Tribüne" has made an approximate estimate of how much reparations England and the USA have already received and states that the German foreign investments that are to be handed over to England and the USA are estimated at 3.3 billion dollars. The value of the German merchant fleet in the hands of the Allied Western Powers is 2.2 billion dollars. The German gold and the German patents and inventions confiscated by England and the USA are estimated at 5 billion dollars. In total, that's already 10.5 billion dollars, apart from the confiscated industrial products and the German plants and machines confiscated by the British and Americans and bought up at extremely low compulsory prices.

These facts show that England and the USA are satisfying their reparation claims very extensively, and that the reparations paid to them by Germany already exceed the total reparation demand of the Soviet Union (10 billion dollars).

Moscow about the Patent Loot in Germany. *Die Tat* (Zürich), 20 March 1947, p. 5. http://www.e-newspaperarchives.ch/?a=d&d=DTT19470320-01.2.16

"The seizure of German patents by American and English monopolies" is explained in the Moscow weekly "Neue Zeit" among other things:

As is well known, American and English companies, apart from other acquisitions on reparations accounts, have also acquired large quantities of German patents. In order to get a full idea of the value and significance of this part of the reparations revenue, one must understand the importance of patents in the world economy.

Under modern capitalism, patents are a powerful weapon of monopolies. In many cases, the possession of particularly valuable and important patents served as the basis for international cartel agreements.

Before the Second World War, the large trusts of the USA, England, and Germany had concentrated hundreds of thousands of patents in their hands, most of which were never exploited but served as a means of squeezing competitors.

At the American military government in Germany, in Frankfurt am Main, a special apparatus was created under the name Field Information Agency Technical, which was subordinate to General Clay. In this institution there is a special "Technical Intelligence Branch" which has a rich engineering staff in various fields and specialists in photophotography. The US Department of Commerce has a so-called Office of the Publication Board, which, through a decree of President Truman under No. 9604, is responsible for collecting information about scientific and technical achievements, inventions, improvements, etc. in enemy and liberated countries; notice that this recollection has been made mandatory by the decree. This office forwards requests from American industry to the aforementioned bodies of the occupation authorities and informs them of their needs.

John C. Green, the executive secretary of the mentioned publication office, reports in the Journal of the American Chemical Society the following about the methods used in obtaining patents from Germany:

A group of specialist engineers, supported by qualified German scientists and engineers, who have been examined by the military authorities, appear at a research institute, laboratory or company, carefully familiarize themselves with the technological process or research topic and determine which technical or... scientific achievements, inventions and perfections have been achieved here over a longer period of time. Afterwards, German microphotographers, under the supervision of the Americans, photograph these materials on microfilm, while the first working group (that began to collect) goes off to visit the next target. The microfilms are developed in Frankfurt, cataloged using a carefully developed system and sent to the USA. By the fall of 1946, of the 3.5 billion pages of technical documents these groups had produced that were of value to American industry, 3.5 million pages had been microfilmed. John Green shares:

"Among the stacks of data recently discovered and continually microfilmed by the search groups are all the valuable inventions that the IG-Farben industry has applied for patents or was about to do so with the German Patent Office."

Green rightly adds: "Apparently these are reparations in the most productive sense of the word." The above-mentioned publication office at the US Department of Commerce not only deals with the publication of patents, drawings, chemical recipes and the like, it also generously sends scientists and qualified engineers from the industrial trusts to Germany so that they can be on site to familiarize themselves with the activities of the relevant German industrial sectors. These scientists and engineers visit important companies and research laboratories of this or that branch of the economy, collect technical information and write detailed reports. After that they return to their jobs at the concerned companies, which cover all expenses for these business trips.

The listed methods for acquiring German scientific and technical experience are essential additions to the ownership of German patents, since the exploitation of patents is now often only possible if the corresponding production experience is available, which the Americans call "know how" ("wissen wie"). Without such detailed experimental knowledge, the patent can remain dead capital.

In addition to the patents exported from Germany, the Foreign Property Trust Administration in the United States, which was liquidated in the fall of 1946, held in its hands 45,000 patents, about 500,000 copyrights and a number of other technical documents that belonged to German (but also Japanese) citizens in the United States.

This category of reparations, from the strictest industrial secrets to the subordinate problems of production technology, is one of the richest spoils of war that has ever fallen to a victor.

Pravda: German Patents in the US and England. *Die Tat* (Zürich), 7 April 1949, p. 5. http://www.e-newspaperarchives.ch/?a=d&d=DTT19490407-01.2.29

N. Kharlamov writes about this and among other things reports the following:

Anglo-Saxon propaganda has long been campaigning for the complete cessation of reparations deliveries to the countries devastated by Hitler's aggression, whose legally justified demands are ignored because the ruling circles in the USA are focused on and have taken the decision of restoring West Germany's defense industrial potential. The "Voice of America" recently announced that the

United States was not interested in German reparation payments.

On the other hand, we know from numerous clearly established incidents how blatantly unembarrassed the occupation authorities in the western zones of Germany are sounding and acting, and that practically—from the very beginning—the United States and England have extracted, and are still extracting, huge reparations from Germany. The German patents and inventions, which have already brought American and English companies billions of dollars in profits, are just one but nevertheless very striking example of what is happening. The value of the German patents confiscated by the US as "spoils of war" alone was estimated at more than 5 billion dollars by the "Berlin Information Letters" published by the French Military Government in Berlin, an estimation based on original American sources. And it should be taken into account that the exploitation of patents is only a part of the hidden and disguised reparations that the Western powers are taking from Germany.

For over three years, hundreds of engineers and technicians from the American 'Office of Technical Services' have been working to sort, register and examine German patents brought to the United States, documents that weigh a total of more than 10,000 tons!

But not all German patents and documents about technological processes and scientific discoveries crossed the ocean; some remained in Germany and were brought to Höchst am Main, where the American authorities opened a kind of branch of the "New York Central Office for the Processing of German Patents."

Several hundred scholars and engineers select the most valuable documents at this place and record them on microfilms, which are then sent every month to the USA, to the Office for Technical Information. Every month 30,000 meters of microfilmed documents are viewed and prepared for distribution to American companies as is also confirmed by the "Berliner Informationsbriefe" ('Berlin Information Letters'). According to available information, more than 5 million meters of microfilms have already been sent to the USA.

Before the above-mentioned branch was set up in Höchst, the "Technical Intelligence Branch" carefully searched German companies and research institutes for documents on industrial planning, patents, new production methods, technological processes, etc. and found extremely valuable and unique machines and devices that were transported across the Atlantic. But in addition to the organs of the technical service of the US Army, special industrial missions were also busy with this task, which were directly interested in this or that branch of industry, such as the Schröder-Mission, which was launched immediately after Germany's surrender and crossed the Atlantic to obtain material about the latest achievements of German technology in the field of producing synthetic fuel. Supported by US troops, the German chemical companies were carefully combed and the most valuable patents, samples of unique equipment and confidential documents were brought to the US to be studied there with the active participation of German scholars and then incorporated into the American industry. The Office for Technical Information is literally overwhelmed with orders from American companies for German patents. Every day they receive around 20,000 requests from all parts of the country, with orders from large corporations such as Dupont, International Harvester Company, etc. being preferred. Patents worth tens and hundreds of thousands of dollars are sold to the largest monopolies at ridiculous prices of 6 to 17 dollars. In London, an analogous office, the "German Patents Registration Office," where German inventions are registered, sells the patents to the English monopolists for 2 shillings 6 pence! Despite these low prices, the New York headquarters have already collected hundreds of thousands of dollars. As the "Berliner Informationsbriefe" ('Berlin Information Letters') report, this institute recorded a net profit of over 100,000 dollars in 1947 alone.

This huge demand from Anglo-Saxon industry for German patents is quite understandable, since American specialists openly described them as “invaluable,” gold mines of information for both military research and private industry. On November 7, 1948, the “Berliner Zeitung” reported that an American chemical company was using a German process to make synthetic rubber more resistant, others were using German patents to create new textile fibers, and still others were using German polyurethane to make high-quality bristles, fibers and coating compounds. More than 65,000 documents on technical information captured at the chemical plants of the IG group are being used to produce chemicals, dyes, medicines, alloys, and color photographic processes that were previously unknown in the United States.

These “technical achievements”—the American press makes no secret of them—have brought enormous profits to the chemical companies in the USA and made it possible to quadruple the export of chemicals compared to the pre-war years, as the US was able to take control of the former German sales markets, as confirmed by the “Chemical and Engineering News.” The Winthrop Chemical Company produces a German substitute for morphine in large quantities, the Stearns & Co. produces adrenaline derivatives according to German patents and models, and other companies produce a painkiller “Methadone” invented by German chemists, which was previously known and sold as “Drug 10820” in Germany. The Wall Street Journal wrote: “Our country has become the heir to the relinquished empire of the German I.G. Farbenindustrie, and it intends to remain in its possession.”

In England and her Dominions this exploitation takes place in the same manner. In England, for example, cameras were manufactured which are an exact copy of the German “Leica”; in 1949 10,000 such devices were to be exported. On 25 December last year the London radio explained that, through London, Australia had also received 4,000 reports on German technical processes that had been developed by German industry during the war.

Of course, special attention is paid to German patents in the field of war. The Anglo-Saxon intelligence service had very carefully collected the material about the headquarters of German military research centers, so that when they invaded Germany, immediately behind the front troops, technical specialists (so-called “investigation teams”) immediately began to “acquire” the objects assigned to them. These specially trained squads proved to be excellently informed over the personnel and local conditions. For example, when Schongau was taken, an American officer immediately asked for Dr. Steinhoff, the head of the “Electromechanical Works” that had been relocated there, and quickly took him and his 500-man group into custody.

Already by September 1945, these teams had collected 160 different types of rocket projectiles at various stages of their manufacture and sent them to the US along with 150 tons of confidential drawings and documents on aircraft and engine construction, production of flying rockets, etc., which then became the basis for the creation a network of research institutes, laboratories and experimental bases.

England and the countries of the Empire have begun large-scale work on the same basis, which is mainly led by the Research Council for Aeronautics of the Nations of the British Empire, whose principal Director of Scientific Research, Sir Ben Lockspeiser, declared recently in Melbourne that Australia and New Zealand should be made the centers to implement the British research program and that £30 million should be made available to Australia for this research.

The above facts prove that the Western occupying powers received, as disguised reparations, German patents that are worth billions of dollars, and further prove that these patents are intended to be used to prepare for a new war.

[The above 3 articles were written for Soviet political purposes yet contain many interesting details.]

11.2 General Approaches Transferred from the German-Speaking World

After absorbing a huge number of German-speaking creators and creations, the U.S. research system had a very productive period during World War II and in the first decades after the war. During this period, the U.S. system also seems to have followed many of the approaches that had made the earlier German-speaking scientific world so successful, such as rapidly increasing research funding, management of the research system by enlightened despots, and other practices. Most of these approaches did not persist more than a few decades (beyond 1970 or so), which may help explain the apparent decline in the number of revolutionary new innovations in more recent times.

During the 1940s–1960s, the U.S. research system publicly unveiled a number of major inventions and discoveries. As covered in Chapters 2–9, 11.1, and the appendices, those innovations were generally adopted and developed from earlier German-based creations. Nonetheless, their implementation in the United States demonstrated that the U.S. system at that time was capable of carrying out revolutionary work that seems to be much less common now:

- During World War II, high-priority government programs created fission bombs and reactors, developed radar, mass-produced penicillin, and fielded other revolutionary technologies with military applications.

- Similarly, during the Cold War, high-priority government programs developed hydrogen bombs, nuclear submarines, intercontinental ballistic missiles, jet fighters, advanced air defense systems, satellites and spacecraft, computers, and other technologies.

- During the first few postwar decades, U.S. industry produced transistors, lasers, printed and integrated circuits, molecular medicines, new materials, jet airliners, nuclear power plants, and other very innovative products.

- Also during the first few postwar decades, U.S. academia published major discoveries in particle physics (relativistic quantum physics), molecular and cellular biology, and other areas.

This section examines the general approaches that the United States borrowed from the earlier German-speaking world and that facilitated this 1940s–1960s era of productivity in the U.S. research system. As shown later in this chapter, despite the successes that the United States achieved with the German-like general approaches, those approaches were largely abandoned after a few decades.

11.2.1 Cultural Attitudes Toward Science Education and Research

As in the earlier German-speaking world, popular culture in the United States glorified science education and research during the 1940s–1960s. Unfortunately, this attitude appears to have declined starting around 1970 or so. Although it is difficult to quantify such social attitudes with rigorous data, various types of illustrative examples are given here.

U.S. science fiction authors gained increasing prominence in magazines in the 1930s and 1940s, but arguably their greatest impact on children was through juvenile science fiction novels that were written from the late 1940s through the early 1970s, as exemplified by series such as:

- Robert A. Heinlein's juvenile novels. Heinlein was a retired U.S. Navy lieutenant and former engineering student, and was married to a retired Navy lieutenant commander and chemist, Virginia Heinlein [Dick 2008, pp. 341–352]. Heinlein's first novel, *Rocket Ship Galileo* (1947), described how three teenage budding engineers and their adult mentor from the Manhattan Project built a nuclear-powered rocket and traveled to the moon. (Ironically they found that German rocket engineers had secretly already gotten there.) Heinlein wrote a total of 12 juvenile novels through 1958's *Have Space Suit—Will Travel*, each depicting how young people assisted with a further step in space exploration. The popularity of his books prompted other authors such as those listed below to write juvenile science fiction novels [Clute 2017].

- Lester del Rey's juvenile novels. Del Rey was a longtime author, editor, and publisher of science fiction. From 1952 to 1968, he wrote over 20 juvenile novels in which young people created or assisted with projects on space flight (e.g., *Marooned on Mars*, 1952, and *Mission to the Moon*, 1956), submarines (*Attack from Atlantis*, 1953), robotics (*Runaway Robot*, 1965), time travel (*Tunnel Through Time*, 1966), and other innovations [Clute 2017].

- The *Tom Swift Jr.* series, published 1954–1971 by the Stratemeyer Syndicate (which also produced the *Hardy Boys* and *Nancy Drew* novels). Most of the 33 books in this series were written by James Duncan Lawrence, a former mechanical engineer and teacher. As depicted in these books, Tom Swift Jr. was a young inventor who used the resources of his father's large engineering company to build a series of increasingly sophisticated aircraft, spacecraft, submarines, robots, atomic devices, and other creations [Jonathan Cooper 2007; Open Library 2010].

- Bertrand Brinley's *Mad Scientists' Club* stories. Brinley was a retired Army captain, whose Army duties had included (among other things) advising children on how to safely experiment with rockets in the 1950s. Based on that work, he published the detailed nonfiction *Rocket Manual for Amateurs* in 1960, followed by a series of 1960–1974 fictional stories about students who formed the Mad Scientists' Club to create and test their own inventions [Brinley 2010].

- The *Danny Dunn* series, published between 1956 and 1977 by Raymond Abrashkin and Jay Williams. The books focused on discoveries and inventions that were made by young students and adult scientists usually working together. The discoveries and inventions combined some real-world scientific ideas and approaches with very fanciful science fiction adventures designed to appeal to young readers [Clute 2017].

Like their predecessors in the earlier German-speaking world (see p. 1968), these books presented children with fictional role models who through their scientific knowledge, hard work, and individualism created revolutionary innovations, despite both scientific obstacles and human opponents.

These books were extremely popular, became fixtures in public and school libraries in the United States, and inspired countless children to pursue careers in science and engineering. However, by the early 1970s, most books like these ceased to be produced, as shifts in children's interests made such books less marketable. More recent juvenile fiction tends to focus on children (e.g., Harry Potter), superheroes (e.g., Marvel and DC characters), or animals (e.g., cats, dragons, etc.) who are magically granted special powers, instead of having to achieve things using scientific knowledge and hard work.

Just as many German engineers had first become interested in their profession as children by watching films like Fritz Lang's *Frau im Mond* (1929), some of the German-speaking scientists who immigrated to the United States attempted to interest U.S. children in science. Examples included:

- Wernher von Braun, Ernst Stuhlinger, and other German scientists collaborated with Walt Disney to produce several entertaining but educational episodes of the *Disneyland* television series: "Man in Space" (1955), "Man and the Moon" (1955), and "Mars and Beyond" (1957) [Michael Neufeld 2007].
- Heinz Haber and other German scientists collaborated with Disney to produce another *Disneyland* episode, "Our Friend the Atom" (1957), that covered nuclear fission and fusion. Haber also wrote a corresponding children's book [Haber 1956].
- Willy Ley wrote popular descriptions of the science underlying rockets and space travel for numerous magazines and books, and was a consultant for television shows ranging from *Tom Corbett, Space Cadet* (adapted from Heinlein's *Space Cadet* novel) to *Disneyland* [Clute 2017].
- George Gamow wrote the *Mr. Tompkins* series of books from 1940 to 1967 to explain various scientific concepts in ways that children could understand [Gamow 1940, 1945, 1953, 1967].
- While not a scientist, George Pal (György Pál Marczincsak, Hungarian, 1908–1980) was a skilled German-speaking filmmaker who had worked in Prague and Berlin. He fled the Third Reich, and after the war he used his talents to present positive portrayals of fictional scientists to U.S. audiences in films such as *Destination Moon* (1950, adapted from Heinlein's *Rocket Ship Galileo*), *When Worlds Collide* (1951), *The War of the Worlds* (1953, adapted from the H. G. Wells novel but focusing on a scientist), *Conquest of Space* (1955, about a manned mission to Mars), and *The Time Machine* (1960, also adapted from an H. G. Wells novel).

Many scientists and engineers were first inspired by educational science kits that they experimented with as children. The early to mid-twentieth century, and especially the 1940s–1960s, were a golden age for such kits in the United States:

- A. C. Gilbert, an M.D. from Yale University, founded the A. C. Gilbert Company in 1909 in New Haven, Connecticut to produce science- and engineering-related kits for children. His sales steadily increased until World War II but really boomed after the war from the late 1940s until the 1960s. Gilbert's kits included Erector Set engineering construction kits for building everything from robots to locomotives; chemistry sets with dozens of chemicals; high-quality compound microscopes with slide-making accessories; and even the "U-238 Atomic Energy Lab" that provided children with several real uranium ore samples, other radioactive sources, a Geiger counter, a cloud chamber, an electroscope, and other nuclear physics supplies. However, Gilbert died in 1961, his company merged with the rival Porter company in 1967, and the combined company (Gabriel Industries) slowly petered out during the 1970s [Gilbert and McClintock 1954; Jitterbuzz 2017; Bruce Watson 2002].

- Harold Porter founded the Porter Chemical Company (Chemcraft) in 1914 in Hagerstown, Maryland to also produce science and engineering kits. The company's history very much paralleled that of the rival Gilbert company: sales increased until the wartime shortages of World War II, but then blossomed into a golden age from the late 1940s to the 1960s. Porter's products included lavishly equipped chemistry sets but also mineralogy kits, biology dissection sets, and a variety of microscopes. Porter died in 1963, and in 1967 Gabriel Industries bought and merged the Porter and Gilbert companies. The combined Gabriel company operated with declining sales and declining kit quality through the 1970s, changed hands in 1978, and finally ceased operations entirely in 1984 [Tyler 2003].

- The Skil-Craft company started up in the 1950s in Chicago to compete with the Gilbert and Porter companies in the postwar boom of demand for science and engineering kits. During the 1950s and 1960s, Skil-Craft produced high-quality kits in chemistry, microscopy, and other scientific fields. In 1968 they were bought out by Western Publishing/Golden Books, resulting in several 1970 sets in chemistry, biology, microscopy, and geology that combined Skil-Craft's well-thought-out experiments and Golden Books's beautiful illustrations [Fichter 1970a, 1970b; Parker and Martin 1970a, 1970b, 1970c]. Unfortunately, sales declined in the 1970s, the company changed hands in 1979, and operations ended in 1984.

In the 1940s–1960s, scientific innovators and innovations were widely and prominently heralded in news magazines, newspapers, and other media. Scientists and engineers were viewed as national heroes to be rewarded with fame and adulation, and to be presented as role models for young potential future scientists.

One especially illustrative example was the covers of *Time* magazine. *Time* was arguably the preeminent weekly news magazine in the United States during that period, and each issue's cover showcased an individual (or sometimes a group of individuals or an object) that was deemed to be especially important and newsworthy. Most of the covers featured political or military leaders from the United States or other countries, yet during the 1940s–1960s, a surprising number of *Time* covers were science-related, as listed in Tables 11.8 and 11.9. These *Time* covers featured [https://content.time.com/time/coversearch/0,16871,,00.html]:

- Most of the "enlightened despots" from Section 11.2.6 who directed U.S. research and development (e.g., Wernher von Braun, Vannevar Bush, James Conant, Lee DuBridge, Crawford Greenewalt, George W. Merck, Robert Oppenheimer, Hyman Rickover, Simon Ramo and Dean Woolridge, Bernard Shriever, Edward Teller, and Thomas Watson, Jr.).

- Scientists (e.g., Albert Einstein, Alexander Fleming, Edwin Hubble, Willard Libby, Jonas Salk, Glenn Seaborg, etc.).

- Test pilots and astronauts who piloted some of the newest inventions (e.g., Neil Armstrong, John Glenn, Alan Shepard, Chuck Yeager, etc.).

- Revolutionary innovations (e.g., computers, nuclear weapons, rockets, etc.)

- Whole categories of people. In 1961, *Time* declared all "U.S. Scientists" to be its "Men of the Year." It devoted an issue to "Great College Teachers" in 1966, and another issue to breakthroughs in "U.S. Medicine" in 1969.

Year	**Issue**	**Person or object**	**Subject**
1944	April 3	Vannevar Bush	"General of Physics"
1944	May 15	Alexander Fleming	Penicillin
1946	July 1	Albert Einstein	$E = mc^2$
1946	September 23	James Conant	Science education
1948	February 9	Edwin Hubble	Expanding universe
1948	July 19	Howard Hughes	Hughes Aircraft R&D
1948	November 8	J. Robert Oppenheimer	Science education/nuclear physics
1949	April 18	Chuck Yeager	Mach 1 rocket plane
1950	January 23	Mark III Computer	"Can man build a superman?"
1950	August 28	Irving Langmuir	Atmospheric science
1951	April 16	Crawford Greenewalt	Revolutionary new chemicals
1951	July 23	David Sarnoff	Electronics R&D
1952	August 18	George W. Merck	Revolutionary new pharmaceuticals
1952	December 8	Space Pioneer	"Will man outgrow the earth?"
1953	November 16	Igor Sikorsky	Helicopters
1954	January 11	Hyman Rickover	Nuclear-powered submarines
1954	March 29	Jonas Salk	Polio vaccine
1954	April 12	H Bomb	Nuclear weapons development
1954	June 14	J. Robert Oppenheimer	Nuclear weapons/security
1955	March 28	Thomas Watson, Jr.	Computers
1955	May 16	Lee DuBridge	Science education
1955	August 15	Willard Libby	Nuclear R&D
1956	January 30	"The Missile"	Rockets/nuclear technologies
1957	April 1	Bernard Schriever	Missile and rocket technologies
1957	April 29	Simon Ramo & Dean Woolridge	"Engineers"
1957	November 18	Edward Teller	"U.S. Science: Where It Stands Today"
1958	February 17	Wernher von Braun	Space program
1959	January 19	"Space Exploration"	"U.S. v. Russia"
1959	May 4	James Van Allen	Explorer I satellite/radiation belts
1959	September 14	James Conant	"U.S. Public Schools"
1959	July 27	John Heller	Cancer research

Table 11.8: Some science-related covers of *Time* magazine during the 1940s–1950s.

Year	**Issue**	**Person or object**	**Subject**
1960	March 28	Jacques Cousteau	Undersea exploration
1960	June 6	Satellites	Space program
1961	January 2	"U.S. Scientists"	Men of the Year
1961	January 6	Harry Felt	Advanced aircraft, missiles, subs
1961	January 13	Ancel Keys	Human physiology
1961	April 21	Yuri Gagarin	First man in orbit
1961	May 12	Alan Shepard	First American in space
1961	July 7	Leonard Larson	Medical improvements
1961	October 27	Tom Jones (Northrop)	Aerospace industry
1961	November 10	Glenn Seaborg	Nuclear physics
1961	November 17	John Enders	Virology
1962	March 2	John Glenn	First American in orbit
1963	May 24	Gordon Cooper	Another American in orbit
1963	August 23	U.S. Atomic Arsenal	Nuclear weapons development
1964	January 10	Buckminster Fuller	Engineering/architecture
1964	September 25	Nuclear Issue	Nuclear weapons development
1965	March 26	Alexey Leonov	First spacewalk
1965	April 2	"The Computer in Society"	Computers
1965	May 14	"The Communications Explosion"	Communications technologies
1965	June 11	Ed White and James McDivitt	First American spacewalk
1965	August 27	Chris Kraft	NASA Mission Control
1965	December 24	Gemini Rendezvous	Docking in orbit
1966	May 6	Great Teachers	Importance of high-quality education
1967	February 3	Roger Chaffee, Gus Grissom, Ed White	Apollo 1 fire
1967	April 7	The Pill	Oral contraceptives
1968	December 6	Race for the Moon	Space program
1969	January 3	William Anders, Frank Borman, Jim Lovell	Men of the Year (first around Moon)
1969	February 21	U.S. Medicine	Needed medical improvements
1969	March 14	Great Missile Debate	Rockets/nuclear technologies
1969	July 18	Lunar Exploration	Space program
1969	July 25	Neil Armstrong	First men on Moon

Table 11.9: Some science-related covers of *Time* magazine during the 1960s.

While the specific example of *Time* magazine covers has been cited here, this public praise and attention for scientists, engineers, and their accomplishments occurred throughout popular media during the 1940s–1960s. Hollywood made a film celebrating the scientific development of the U.S. atomic bomb (*The Beginning or the End*, 1947), with actors portraying J. Robert Oppenheimer, Enrico Fermi, Vannevar Bush, Albert Einstein, and other scientists and engineers. Countless other films, television shows, and books focusing on real or fictional scientists were produced during the 1940s–1960s. The national news was dominated by the latest plans and accomplishments of the Space Race throughout the late 1950s and the 1960s. In a 1960 speech to the American Association for the Advancement of Science, the British novelist and chemist C. P. Snow proclaimed [Snow 1961]:

> Scientists are the most important occupational group in the world today. At this moment, what they do is of passionate concern to the whole of human society.

This popular support for scientists went up to the highest levels. For example, President Franklin Roosevelt sent a letter to J. Robert Oppenheimer, the physicist in charge of the Manhattan Project, on 29 June 1943 [https://www.albuqhistsoc.org/source-documents/letter-fdr-oppenheimer/]:

> My dear Dr. Oppenheimer:
>
> I have recently reviewed with Dr. Bush the highly important and secret program of research, development and manufacture with which you are familiar. I was very glad to hear of the excellent work which is being done in a number of places in this country under the immediate supervision of General L.R. Groves and the general direction of the Committee of which Dr. Bush is Chairman. The successful solution of the problem is of the utmost importance to the national safety, and I am confident that the work will be completed in as short a time as possible as the result of the wholehearted cooperation of all concerned.
>
> I am writing to you as the leader of one group which is to play a vital role in the months ahead. I know that you and your colleagues are working on a hazardous matter under unusual circumstances. The fact that the outcome of your labors is of such great significance to the nation requires that this program be even more drastically guarded than other highly secret war development. I have therefore given directions that every precaution be taken to insure the security of your project and feel sure that those in charge will see that these orders are carried out. You are fully aware of the reasons why your endeavors and those of your associates must be circumscribed by very special restrictions. Nevertheless, I wish you would express to the scientists assembled with you my deep appreciation of their willingness to undertake the tasks which lie before them in spite of the dangers and the personal sacrifices. I am sure that we can rely on their continued wholehearted and unselfish labors. Whatever the enemy may be planning, American science will be equal to the challenge. With this thought in mind, I send this note of confidence and appreciation.

Although Roosevelt died before the Manhattan Project was completed, later presidents publicly awarded medals of honor to Oppenheimer and many of the other scientists who participated in that and other wartime projects.

As another example of support from the highest levels, President John F. Kennedy made revolutionary scientific and engineering goals the focus of his "Moon speech" at Rice University Stadium in Houston, Texas on 12 September 1962 [https://www.jfklibrary.org/archives/other-resources/john-f-kennedy-speeches/rice-university-19620912; see also Fig. 11.59]:

> Despite the striking fact that most of the scientists that the world has ever known are alive and working today, despite the fact that this Nation's own scientific manpower is doubling every 12 years in a rate of growth more than three times that of our population as a whole, despite that, the vast stretches of the unknown and the unanswered and the unfinished still far outstrip our collective comprehension. [...]
>
> Those who came before us made certain that this country rode the first waves of the industrial revolutions, the first waves of modern invention, and the first wave of nuclear power, and this generation does not intend to founder in the backwash of the coming age of space. We mean to be a part of it—we mean to lead it. For the eyes of the world now look into space, to the moon and to the planets beyond, and we have vowed that we shall not see it governed by a hostile flag of conquest, but by a banner of freedom and peace. We have vowed that we shall not see space filled with weapons of mass destruction, but with instruments of knowledge and understanding.
>
> Yet the vows of this Nation can only be fulfilled if we in this Nation are first, and, therefore, we intend to be first. In short, our leadership in science and in industry, our hopes for peace and security, our obligations to ourselves as well as others, all require us to make this effort, to solve these mysteries, to solve them for the good of all men, and to become the world's leading space-faring nation. [...]
>
> We choose to go to the moon. We choose to go to the moon in this decade and do the other things, not because they are easy, but because they are hard, because that goal will serve to organize and measure the best of our energies and skills, because that challenge is one that we are willing to accept, one we are unwilling to postpone, and one which we intend to win, and the others, too. [...]
>
> The growth of our science and education will be enriched by new knowledge of our universe and environment, by new techniques of learning and mapping and observation, by new tools and computers for industry, medicine, the home as well as the school. Technical institutions, such as Rice, will reap the harvest of these gains.

Like Roosevelt, Kennedy also died before he could see the revolutionary scientific programs he supported come to fruition, but again, later presidents gave public awards to many of the scientists, engineers, and astronauts who were instrumental in those programs.

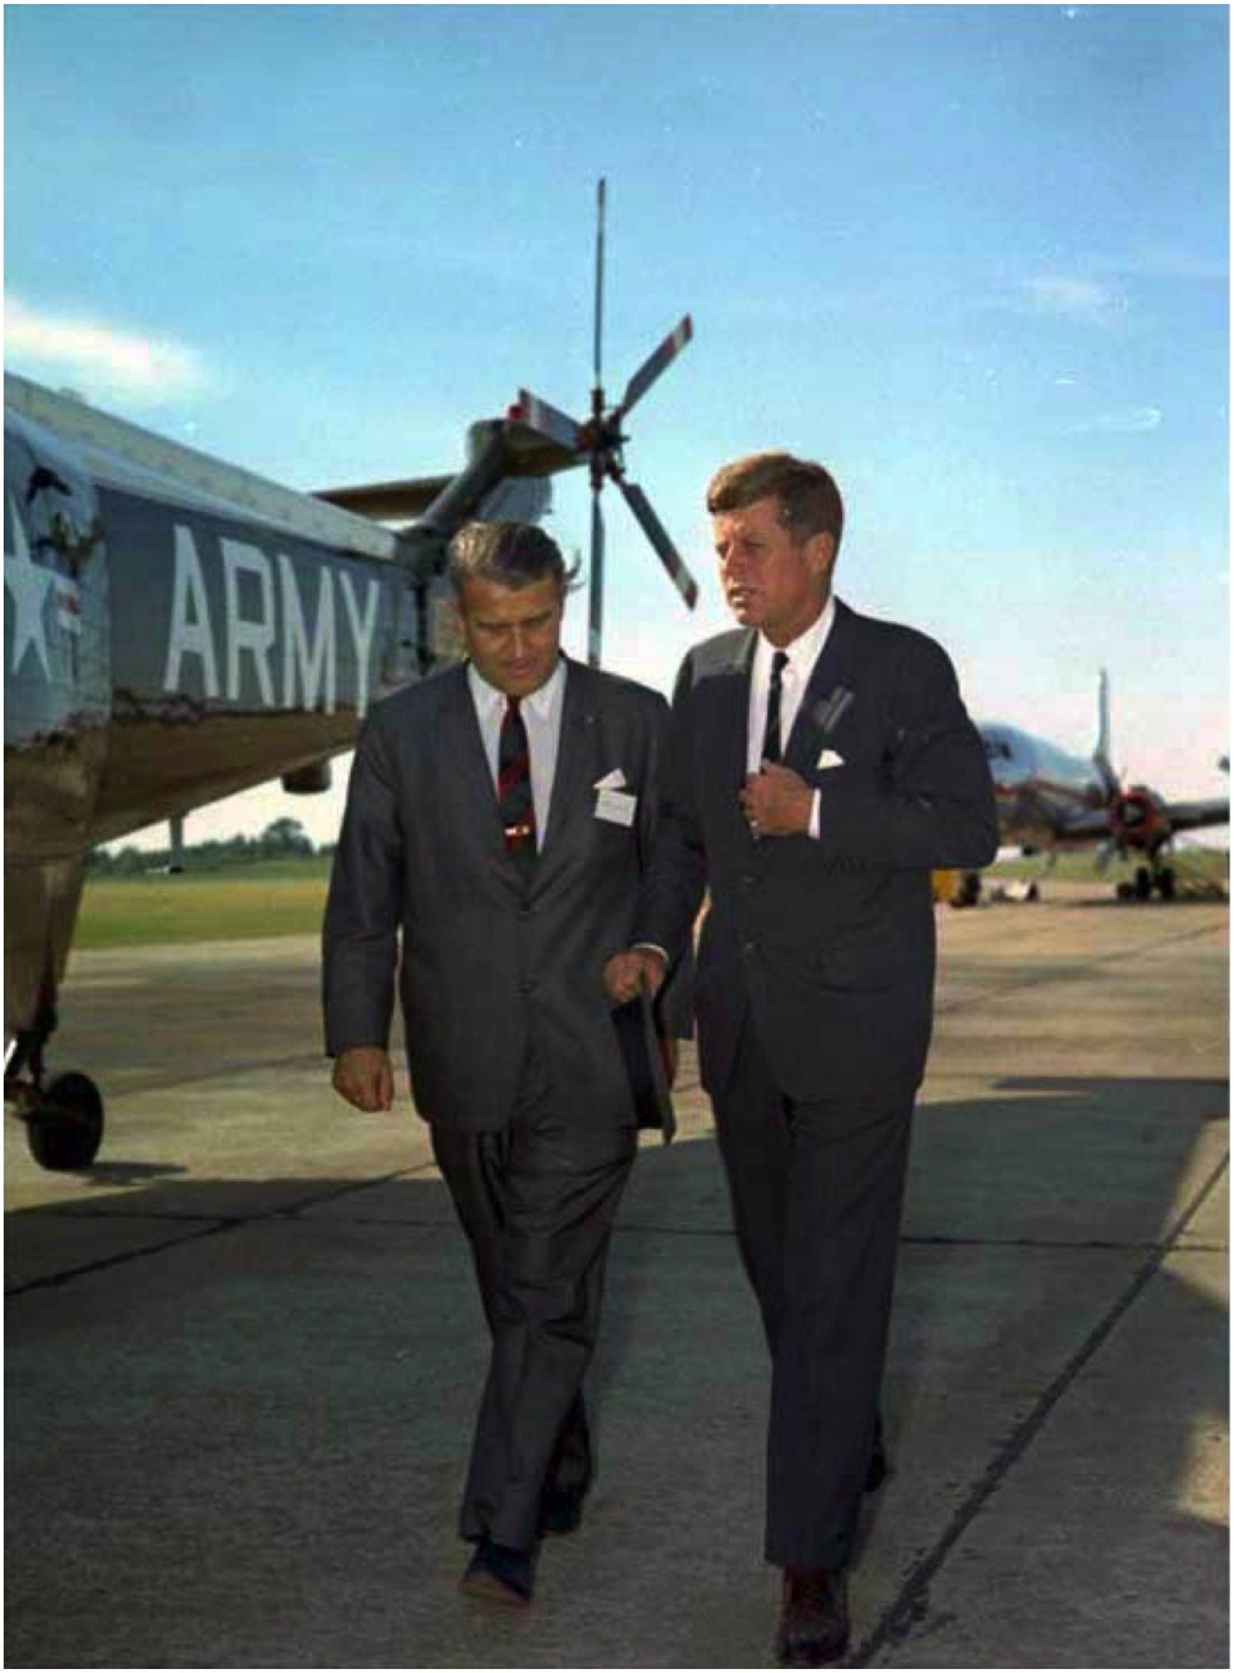

Figure 11.59: Meeting between Wernher von Braun and President John F. Kennedy in Alabama on 19 May 1963.

Unfortunately, by the late 1960s and early 1970s, there was a decline in public interest in and support for science and for scientists in the United States. Some of the factors responsible for that decline included:

- Between the publication of Rachel Carson's book *Silent Spring* in 1962 and the creation of the U.S. Environmental Protection Agency in 1970, there was rising public concern about the personal and environmental risks of new chemicals and new materials that scientists had produced. With the founding of the U.S. Occupational Health and Safety Administration in 1971, there were also greatly increased concerns and lawsuits regarding the safety of new industrial processes, technologies, and products.

- The Space Race between the United States and the Soviet Union, which at the time was probably by far the most visible symbol of scientific progress, essentially came to an abrupt end in 1969 when the United States landed people on the Moon. The Soviet Union chose not to pursue the Space Race beyond that point (for example, by trying to be the first to land people on Mars), and the U.S. government and public rapidly lost interest in sending more people to the Moon or beyond. Without other national scientific goals that were as visible or as compelling as the Space Race, public interest in and support for science education and R&D dropped rapidly.

- By 1972, the majority of U.S. homes had color television, which tempted people with instant and endless gratification instead of applying those extra hours to learn and to create.

- The 1973 and 1979 energy crises and accompanying economic recessions made people, companies, and the government focus more on near-term economic survival than long-term science education and R&D. Later economic booms occurred in other areas of the economy, such as finance and entertainment, drawing further public prestige and interest away from science and engineering.

- Events such as 1970s lawsuits over the U.S. use of the Agent Orange defoliant in Vietnam and the 1979 Three Mile Island nuclear accident tended to create a very negative public perception of science in the United States.

By 2020 and beyond, the U.S. public's general views and treatment of scientists, medical professionals, teachers, other intellectuals, and even basic facts and principles seemed to have fallen very far from the heyday of the mid-twentieth century. Modern examples are too numerous, too well known, and too depressing to recite here.

Looking beyond just science, one could argue that during the 1940s–1960s, there appeared to be widely held U.S. beliefs in doing very high-quality work and in striving to make the world a better place. Millions of Americans worked to overcome the Depression, win World War II, build up U.S. industry, help rebuild Europe and Japan, and oppose the Soviet Union. In contrast, from the 1970s to the current time, it seems that many Americans have been less interested in spending their time and energy to do high-quality work and to improve the world, and more interested in trying to achieve fortune and fame as easily as possible, or in simply withdrawing to be entertained by their various video screens large and small.

11.2.2 Funding Levels

Research and development (R&D) spending is naturally a major factor affecting the performance of the innovation system in the United States or other countries.

Figure 11.60 shows early U.S. federal R&D spending, taken from a highly influential 1947 government report by economist John R. Steelman, who at that time was also the first presidential chief of staff (for Harry Truman) [Steelman 1947]. As shown in the graph, spending was minimal before WWII, reflecting the fact that there was essentially no government-funded research system in the United States, unlike in German-speaking central Europe. U.S. federal R&D spending increased exponentially during WWII, as the government-funded research system came into existence, hired large numbers of talented innovators, and launched programs on revolutionary technologies such as radar, nuclear fission, penicillin mass production, etc. The graph shows that the spending increased more slowly but still exponentially after WWII, with projected increases beyond the current year of 1947 well into the 1950s, as indeed proved to be the case. The figure also explicitly links each funding increase to an increase in the number of "the scientists to do the job."

As an overview of U.S. federal R&D spending from the early postwar period to the present, Fig. 11.61 shows the defense, nondefense, and total spending for government fiscal years (FY, starting October 1 before the corresponding calendar year) since FY 1953, in inflation-adjusted constant FY 2018 dollars. It is especially noteworthy that defense R&D spending doubled practically overnight in FY 1959—that was the first fiscal year of funding that was approved after the October 1957 launch of the Soviet Sputnik satellite. Similarly one can see the rapid increase in nondefense R&D during the early 1960s for the manned space program. There were also increases in military spending during the Reagan administration (1980s) and George W. Bush administration (early 2000s), but the graph shows that those were largely temporary.

To help provide more context for the spending levels, Fig. 11.62 regraphs the U.S. federal R&D spending as a percentage of the U.S. gross domestic product (GDP) for each year. This method can help give a better understanding of how large the research programs were relative to other aspects of the economy, and by extension how much talented labor, resources, and recognition would be drawn to research work versus other occupations in society. Fig. 11.62(a) presents an historical overview for the period 1949–2005, showing that by this measure the total federal R&D funding peaked in 1964 (the time of greatest development work for the space program), began a steep decline around 1967 (once most of the development work for the Apollo-Saturn program had been completed), and continued to decline slowly for decades thereafter. Figure 11.62(b) gives a more detailed graph for the period 1976–2018, showing that the funding has continued to decline to the present, apart from relatively small oscillations (the Reagan and George W. Bush temporary increases in defense spending). In fact, the current total federal R&D spending (approximately 0.7% of GDP) is only about one third of the peak 1964 spending (approximately 2.2% of GDP) and lower than any other post-Sputnik budget.

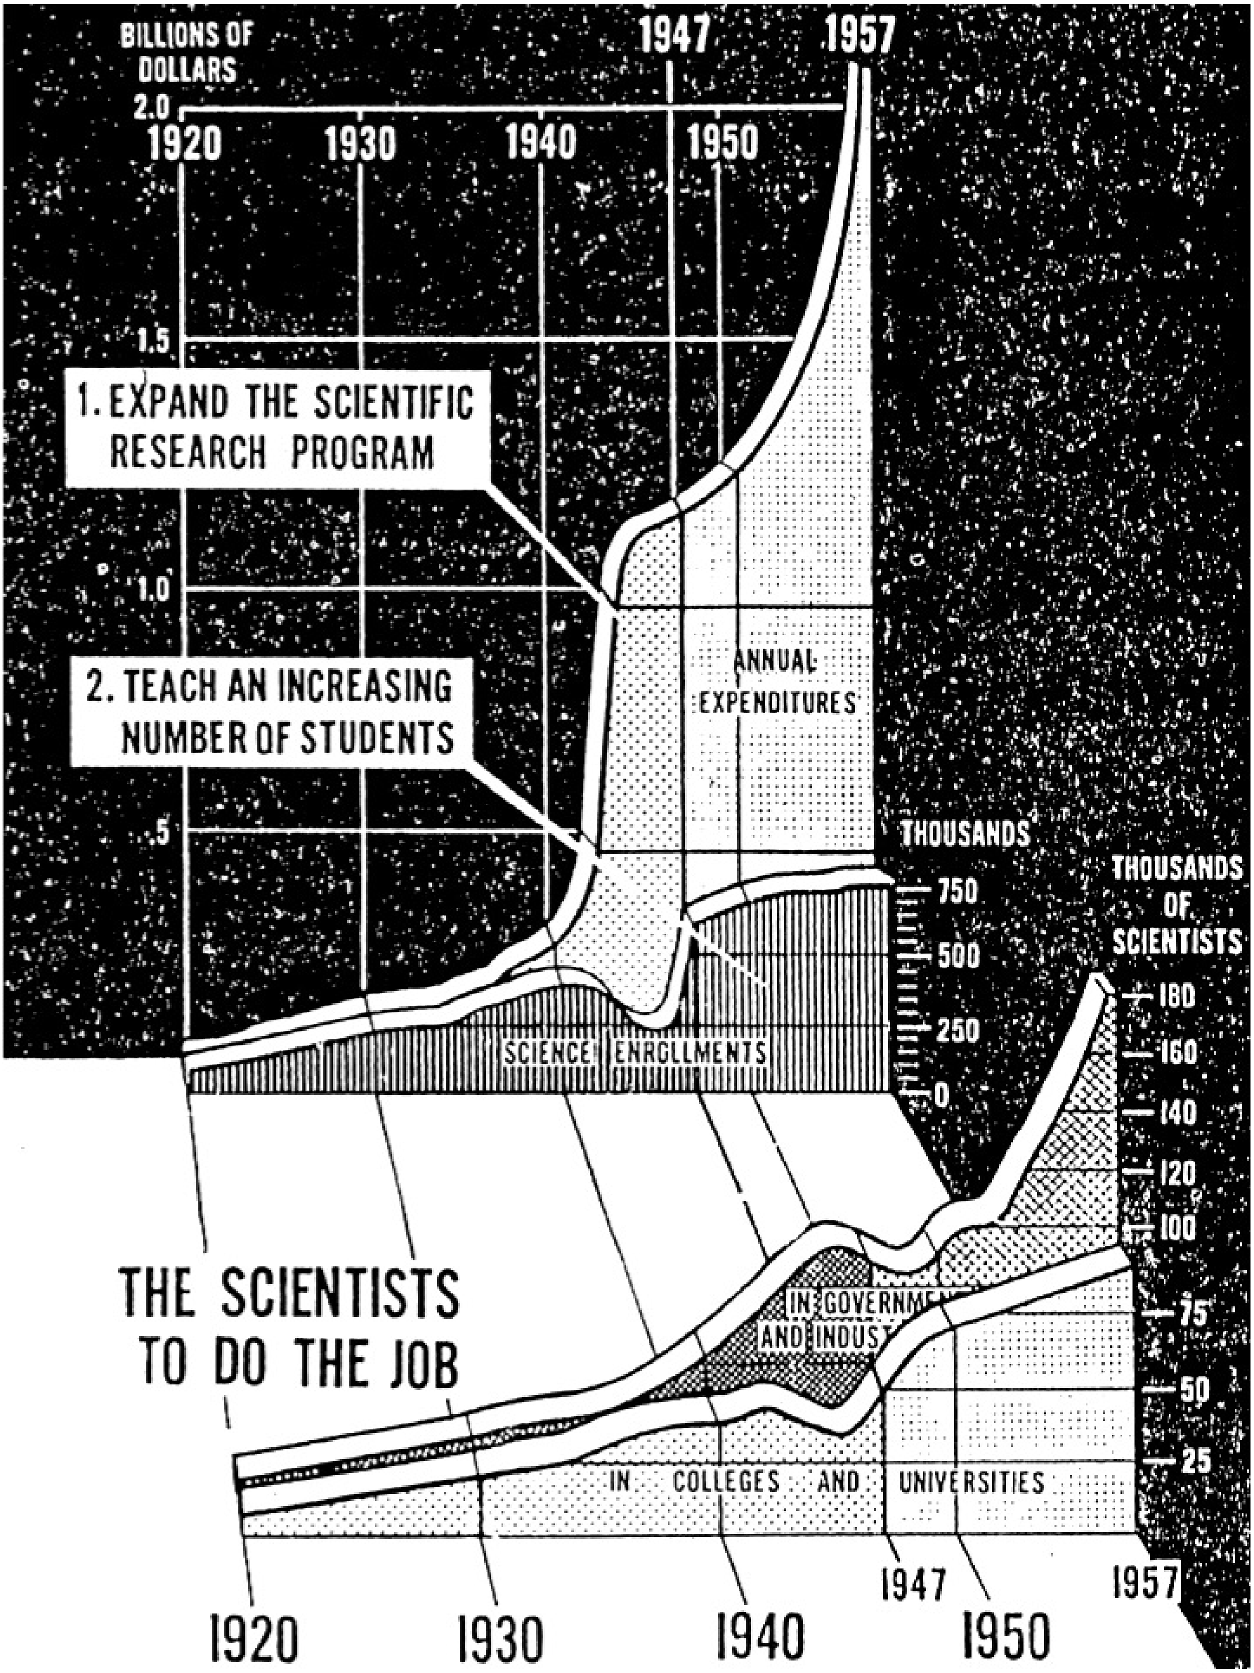

Figure 11.60: This 1947 graph shows that early U.S. federal R&D spending was minimal before World War II, increasing exponentially during the war, and increasing more slowly but still exponentially after the war [Steelman 1947].

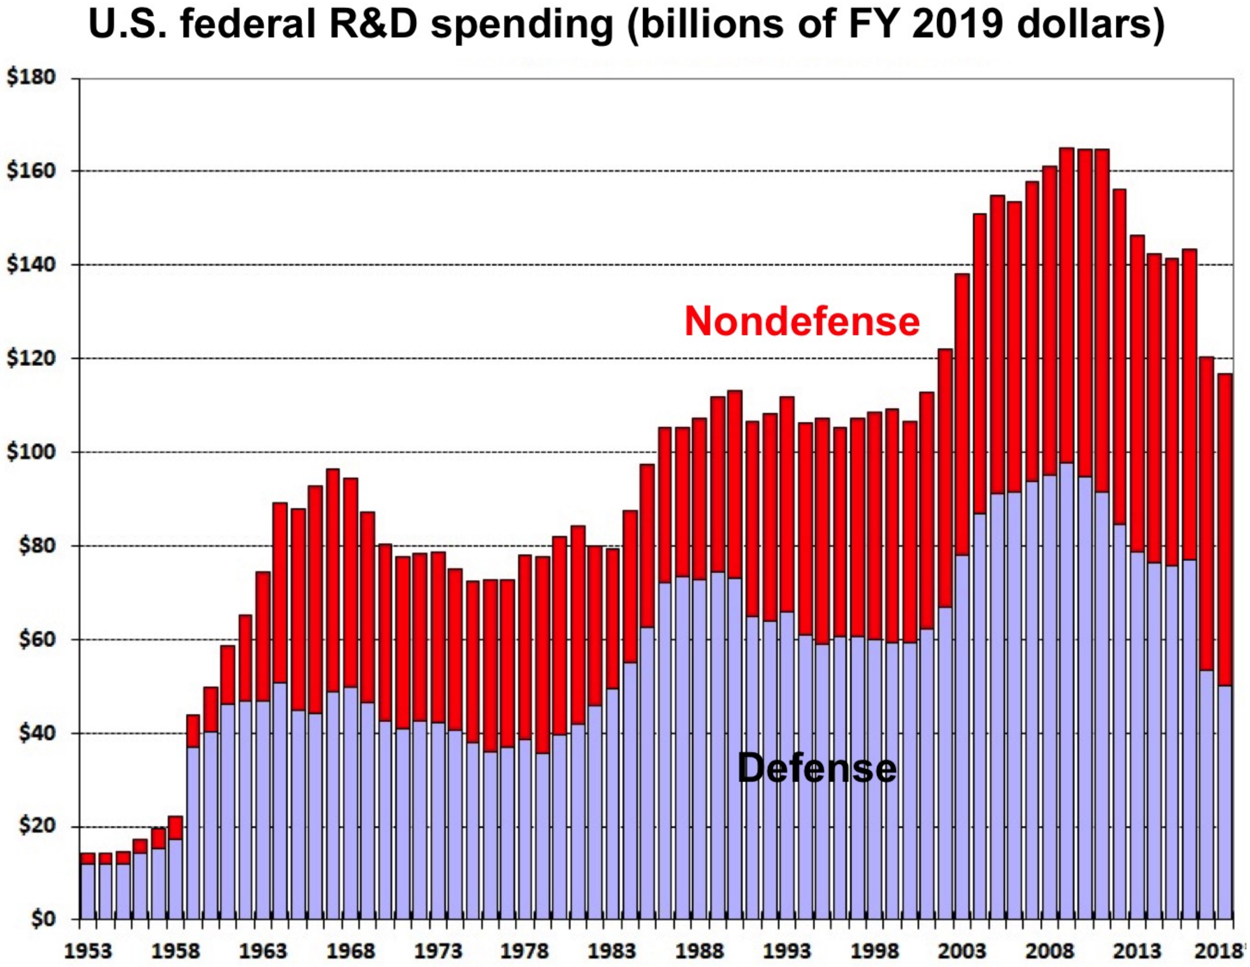

Figure 11.61: U.S. federal R&D spending for government fiscal years (FY, starting October 1 before the corresponding calendar year) since FY 1953, in inflation-adjusted constant FY 2019 dollars. Note the doubling of defense R&D in FY 1959, the first fiscal year of funding that was approved after the October 1957 launch of the Soviet Sputnik satellite, and the rapid increase in nondefense R&D during the early 1960s for the manned space program. Also note the temporary increases in military spending during the Reagan administration (1980s) and George W. Bush administration (early 2000s). The large apparent drop in defense funding in FY2017 is primarily due to a change in what programs were defined as “development” [https://www.aaas.org/programs/r-d-budget-and-policy/historical-trends-federal-rd].

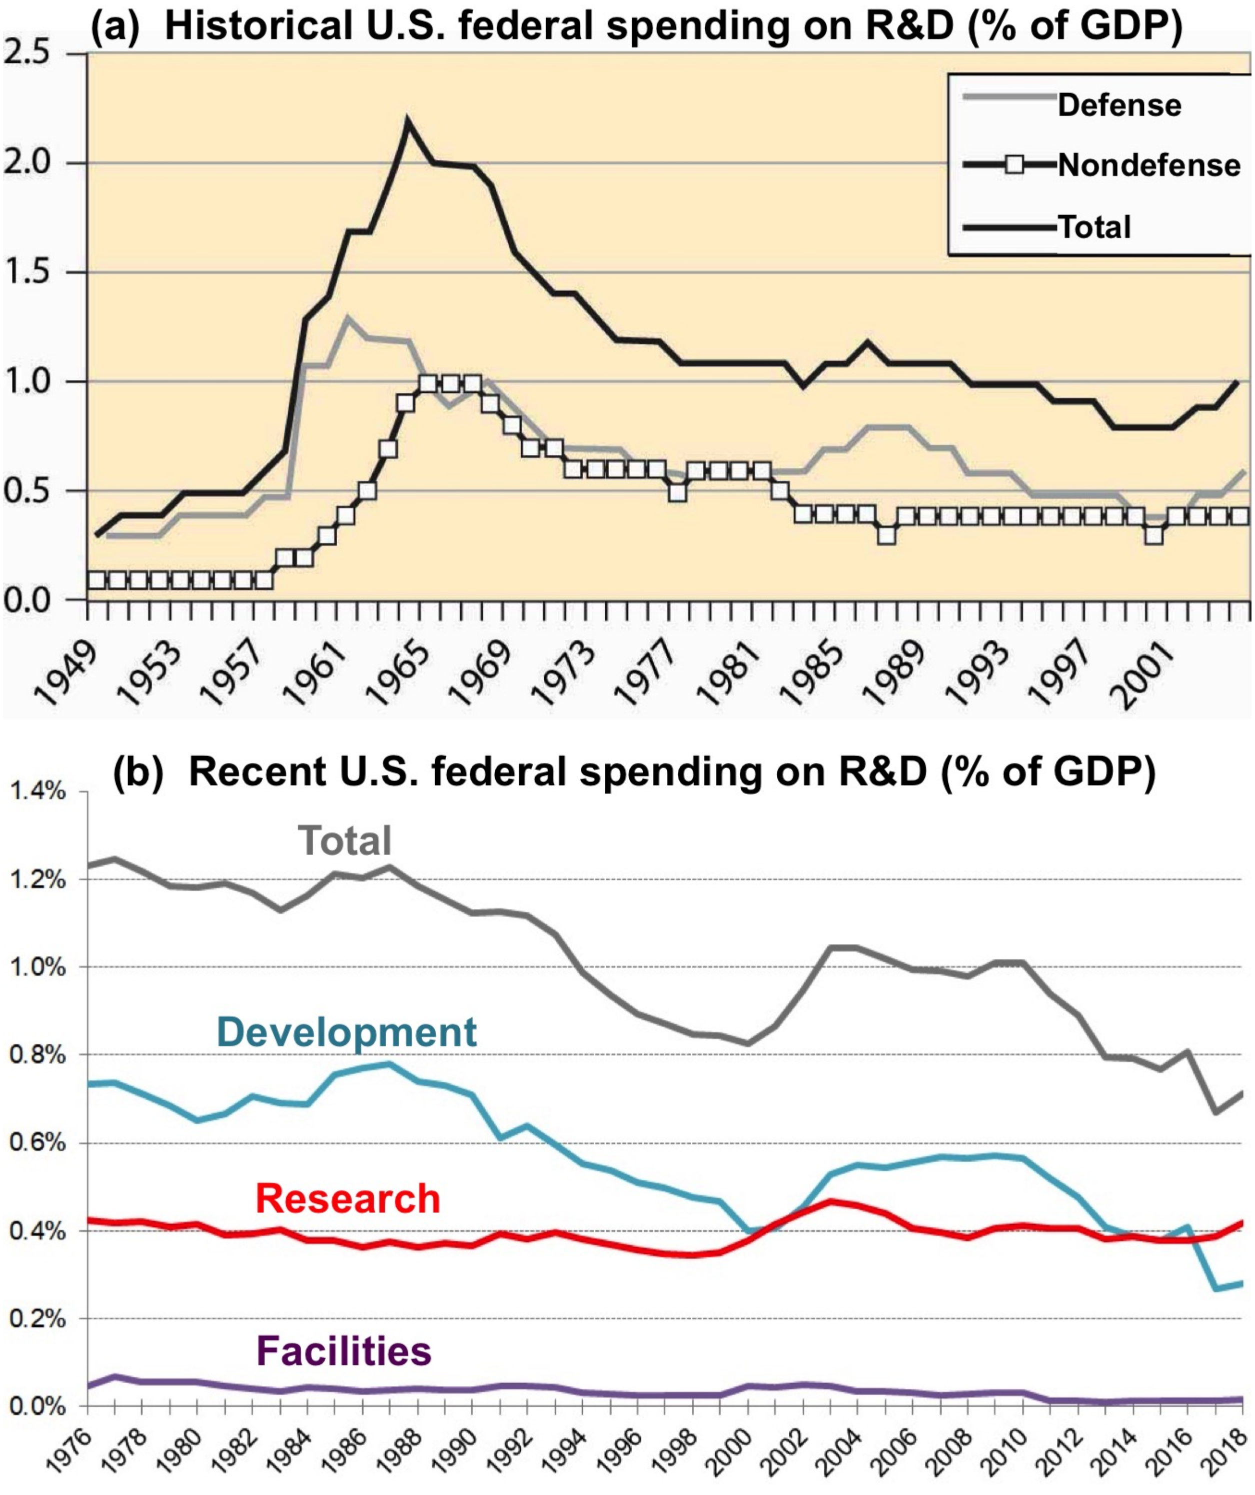

Figure 11.62: U.S. federal R&D spending regraphed as a percentage of the U.S. gross domestic product (GDP) for each year. (a) Historical overview for 1949–2005. (b) More detailed graph for 1976–2018. [https://saylordotorg.github.io/text_introduction-to-economic-analysis/s05-05-government.html#mcafee-ch04_s05_f10; https://www.aaas.org/programs/r-d-budget-and-policy/historical-trends-federal-rd].

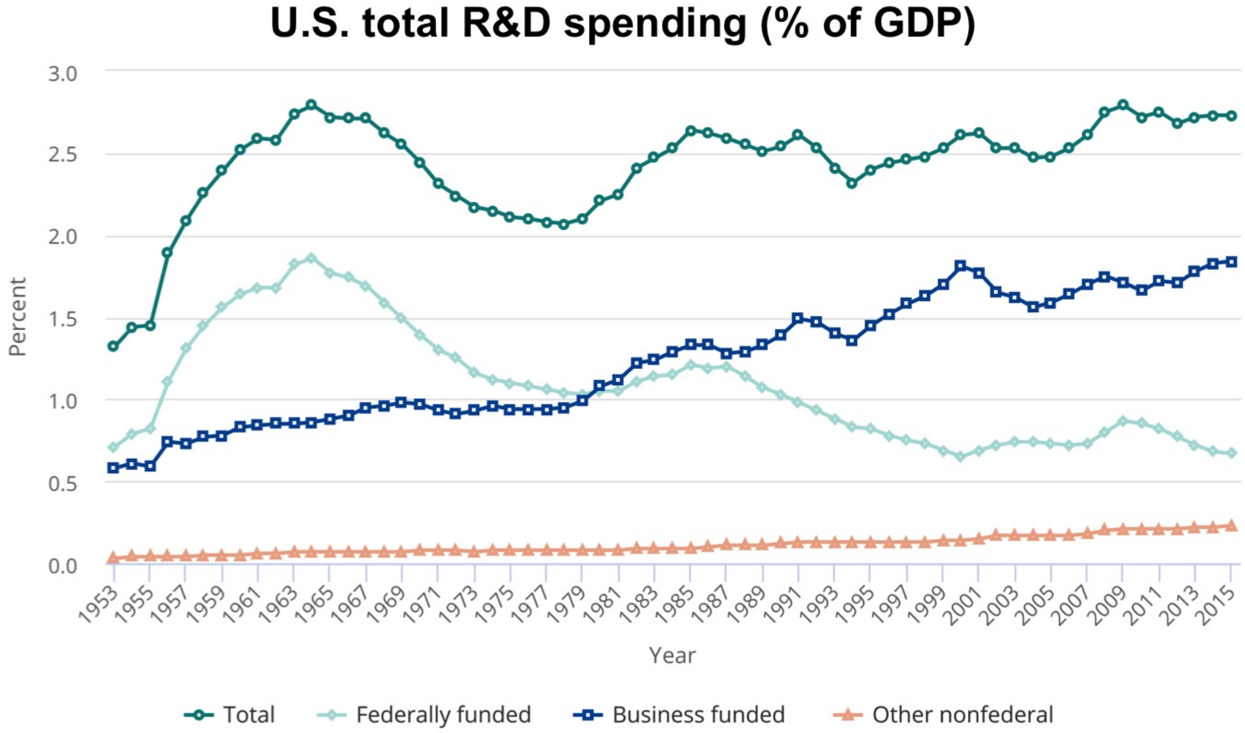

Figure 11.63: U.S. total R&D spending, including federally funded, business funded, and other nonfederal funded work (e.g., by nonprofit foundations or state governments). All spending is expressed as a percentage of the GDP for each year. Taking the numbers at face value, the total U.S. R&D funding as a percentage of GDP has remained roughly constant since the early 1980s. Considering the shift in recent decades from longer-term to much shorter-term R&D, funding for innovative research has actually significantly declined [https://www.nsf.gov/statistics/2018/nsb20181/figures].

Of course, not all R&D spending comes from the federal government. Figure 11.63 shows U.S. total R&D spending, including federally funded, business funded, and other nonfederal funded work. All spending is expressed as a percentage of the GDP for each year:

- As previously shown in Fig. 11.62, the share of federal funding peaked in the 1960s space race and has generally been declining ever since, now down to approximately one third of its earlier peak value.

- Business funding has generally increased steadily, although the quantitative numbers do not indicate the qualitative shift in business R&D from longer-term development of major innovations such as integrated circuits and jet aircraft in the 1950s to immediately marketable products such as smart phone apps in the 2010s.

- Other nonfederal R&D funding (such as by nonprofit foundations and state governments) has been slowly increasing but is still much smaller than federal and business funding.

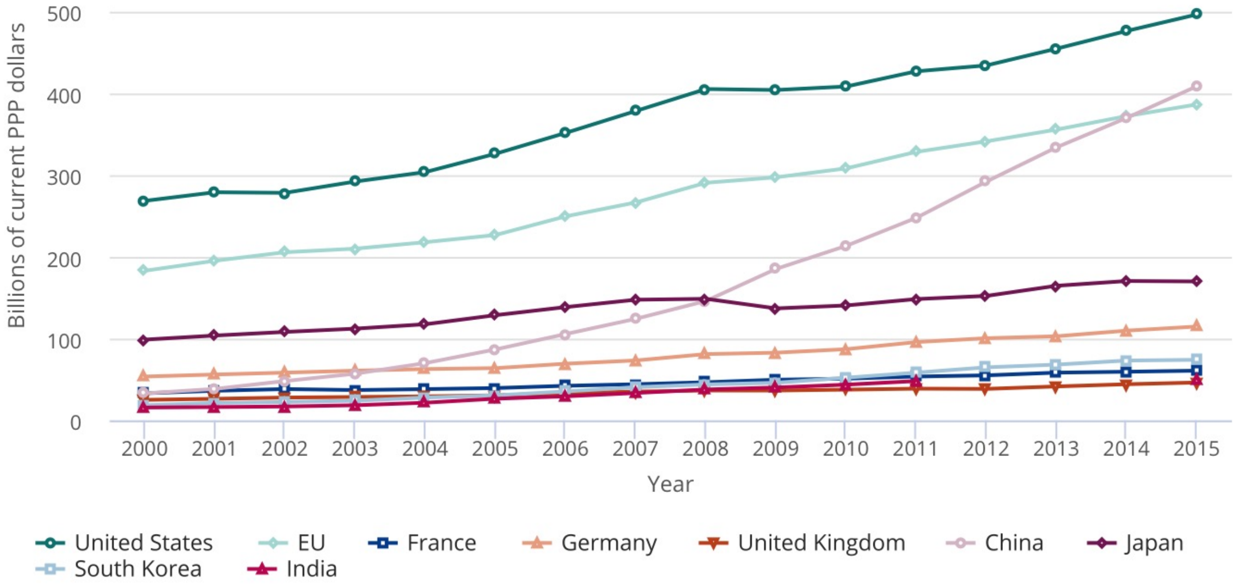
- Even accepting the numbers at face value, the total U.S. R&D funding as a percentage of GDP has remained roughly constant since the early 1980s. With flat funding, effectively the only way for newly graduated scientists and engineers to find a permanent position is to wait for someone older in an existing position to retire or to die. This fact creates pressures that greatly restrict how many new innovators can find employment, and how innovative they are allowed to be under such conservative, resource-limited conditions. Moreover, since over the last several decades more of the available government research jobs have shifted toward bureaucracy, more of the available academic jobs have shifted toward continuous paper and grant writing, and more of the business research jobs have shifted toward producing very short-term, low-risk products, one could argue that the funding for innovative research has significantly declined instead of stayed flat.

For comparison, Fig. 11.64 presents the total R&D spending (from government, industrial, and other sponsors) for a number of other countries, graphed as either purchasing power parity (PPP) dollars or a percentage of each country's GDP for each year. Note that just as R&D spending relative to GDP has been relatively flat in the United States for decades, it has also been fairly flat in most other countries for many years. (As noted for Fig. 11.63, by analyzing the types of R&D activities being supported now versus at earlier times, one might even argue that these apparently flat funding trends have actually been effective declines in innovative research.) From the graph, the most notable exceptions to this trend are China and South Korea, which have each significantly increased their R&D investments. China's R&D increase is especially dramatic, since both China's GDP and its ratio of R&D to GDP have been increasing relatively rapidly.

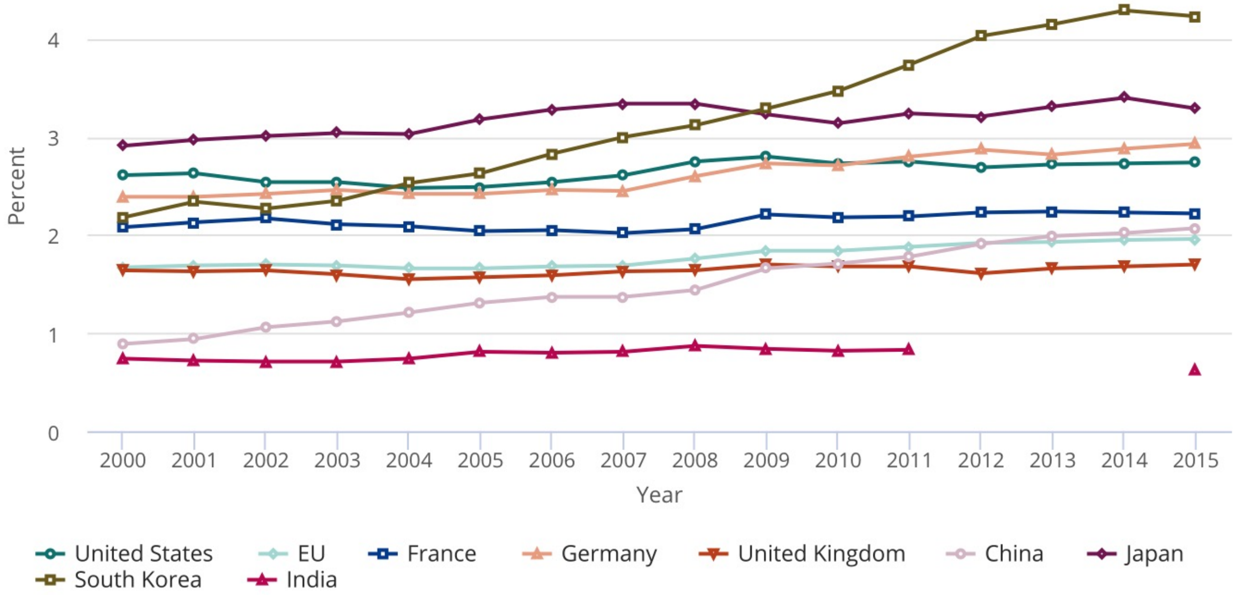
MIT economists Jonathan Gruber and Simon Johnson described the impact of funding changes on the rise and decline of innovation in the United States [Gruber and Johnson 2019, pp. 4–10]:

> In 1938, on the eve of world war, federal and state governments spent a combined 0.076 percent of national income on scientific research, a trivial amount. By 1944, the US government was spending nearly 0.5 percent of national income on science—a sevenfold increase, most of which was channeled through [Vannevar] Bush's organization from 1940. The effects of this unprecedented surge were simply incredible and, for America's enemies, ultimately devastating.

> Then, in 1945, Vannevar Bush had what may be considered his most profound insight. [...]
>
> What was needed next, Bush argued, was a redirection to focus on winning the peace. [...]
>
> From 1940 to 1964, federal funding for research and development increased twentyfold. At its peak in the mid-1960s, this spending amount was around 2 percent of annual gross domestic product—roughly one in every fifty dollars in the United States was devoted to government funding of research and development (equivalent, relative to GDP, to almost $400 billion today). The impact on our economy, on Americans, and on the world was simply transformational. [...]
>
> It is hard to find any aspect of modern life that has not been profoundly affected by innovation that can be traced back either to the Bush-era efforts or to inventions that were supported by various government programs in the years that followed. [...]
>
> Unfortunately, we failed to maintain the [innovation] engine. From the mid-1960s onward, based on concerns about the environmental, military, and ethical implications of unfettered science, compounded by shortsighted budget math, the government curtailed its investments in scientific research. Economic difficulties during the 1970s, followed by the Reagan Revolution and the anti-tax movement, resulted in an even broader retreat from federally funded activities. Most recently, the impact of a global financial crisis in 2008 and consequent economic pressures—known as the Great Recession—have further squeezed investments in the scientific future.
>
> Federal spending on research and development peaked at nearly 2 percent of economic output in 1964 and over the next fifty years fell to only around 0.7 percent of the economy. Converted to the same fraction of GDP today, that decline represents roughly $240 billion per year that we no longer spend on creating the next generation of good jobs.
>
> Should we care? If there is socially beneficial research and product development to be done, surely the innovative companies of today will take this on?
>
> In fact, they won't. [...]
>
> The venture capital sector that has created so many high-tech success stories has, at the same time, avoided the type of very-long-run and capital-intensive investments that lead to technological breakthroughs—and create new industries and jobs.
>
> As a result, the government retreat from research and development has not been fully offset by the private sector.
>
> While we have retreated from Vannevar Bush's innovation engine, the rest of the world is picking up the slack. Total research funding is growing at a much faster rate, relative to the economy, in the rest of the world than it is in the United States, led in many countries by active government policies.



(a) Total R&D spending of various countries in purchasing power parity (PPP) dollars



(b) Total R&D spending of various countries (% of GDP)

Figure 11.64: Total R&D spending for various countries, graphed as (a) purchasing power parity (PPP) dollars, and (b) a percentage of each country's GDP for each year. Note that relative to GDP, R&D spending has been relatively flat for most countries for many years, with the exception of significant investments by China and South Korea [https://www.nsf.gov/statistics/2018/nsb20181/figures].

11.2.3 Mentoring Style

As described in Section 10.2.3, many (though certainly not all) Ph.D. students in the German-speaking world were actively encouraged to independently propose and conduct their own thesis research, thereby honing their skills as highly creative and independent innovators. A number of German-speaking creators described similar experiences during their doctoral research; Section 10.2.3 quoted just a few illustrative examples.

In the early U.S. research system, it is more difficult to find many examples of students who were given such freedom to innovate in pursuing their Ph.D. thesis research. Most thesis topics appear to have been assigned by the Ph.D. advisor, or selected from among a short list of possible topics offered by the advisor, and then closely supervised by the advisor throughout the thesis research. Thus the U.S. students seem to have had fewer opportunities than their German-speaking counterparts to acquire and practice skills at independent innovation early in life.

When biographical and autobiographical accounts of U.S. scientists do reveal that they enjoyed remarkable independence in their Ph.D. thesis research, that independence was often a result of being supervised or assisted by someone who had come from the German-speaking scientific world. For example, historians Lillian Hoddeson and Vicki Daitch described John Bardeen's experiences as a Ph.D. student at Princeton in the 1930s; Bardeen later became the only person to ever win two Nobel Prizes in physics [Hoddeson and Daitch 2002, pp. 50–52, 54–55]:

> Princeton followed suit in 1930, hiring two Hungarian members of the Berlin circle of physics and mathematics, John von Neumann and Eugene Wigner, who were old friends. [...]
>
> Bardeen later wrote that of all his professors at Princeton he was "most stimulated by the two young Hungarians." [...]
>
> In shopping around for a thesis advisor, Bardeen spoke first with [U.S. physicist Edward] Condon, but he found that all of Condon's suggestions concerned filling gaps in the textbook he was then completing with G. H. Shortley, *The Theory of Atomic Spectra.* That "didn't sound too interesting" to Bardeen. [...]
>
> Bardeen decided to throw in his lot with Wigner and never regretted it. He found he needed only occasional meetings to keep his thesis on track. Wigner later told Seitz "that he rarely communicated with Bardeen." But what Bardeen remembered about Wigner was that he always had ways to motivate him with his penetrating questions. Most importantly, Bardeen felt that Wigner instructed him in the art of choosing crucial problems. "He could see what was essential and what the important problems were."
>
> Bardeen also felt that Wigner taught him how to go about attacking problems. The first step was to decompose the problem, either into smaller problems with less scope or into simpler problems that contained the essence of the larger problem. Bardeen said that Wigner stressed reducing to "the simplest possible case, so you can understand that before you go on to something more complicated."

Unfortunately, most Ph.D. thesis advisors in the United States apparently preferred the approach of Condon over that of Wigner (as described by Bardeen), using students as cogs in the machinery to advance the advisors' own research and publications rather than encouraging the students to be as innovative and independent as possible. To succinctly summarize the difference, one might say that the best early German-speaking advisors viewed their roles as *mentors* to offer advice to their students, whereas most native U.S. advisors viewed their roles as *masters* to harness the labor of their students.

In fact, it is remarkable how many creative U.S. scientists studied under German-speaking advisors. In addition to John Bardeen, Eugene Wigner supervised or co-supervised Ph.D. theses for Frederick Seitz, Richard Feynman, and many others. As other examples, Hans Bethe supervised the studies of Jeffrey Goldstone, Roman Jackiw, Freeman Dyson, and others; Victor Weisskopf supervised Ph.D. theses for John David Jackson, Murray Gell-Mann, and other physicists.

Judging from the scarcity of accounts, as the early U.S. research system matured into the modern system, advisors who advocated for students to be as creative and self-directed as possible apparently became ever more scarce. As discussed in the next section, the ages at which students received their Ph.D. also became older. Due to the combination of these two factors, scientists had fewer and fewer opportunities to learn and practice innovation during their formative years.

It should be noted that these problems extend far beyond the United States. The astrophysicist Martin López-Corredoira, who has worked in Spain and Switzerland and gathered information on the academic system worldwide, reported on the common experiences of Ph.D. students in the modern scientific world [López-Corredoira 2013, pp. 62–65]:

> The first contact with research takes place when a graduate student prepares a Ph.D. thesis. [...] If the student wants financial as well as departmental support, then his or her role is to be obedient to, and assimilate, the traditions of the department. [...]
>
> In some cases, the students that do most of the work are not able to write a paper containing their results; the bosses do it instead, as first authors of the paper. Students are told that they do not know how to write their own work. In other cases, when the supervisor sees that things will not have the outcome he or she wants, the supervisor will abandon the student. In some cases, the supervisor steals the student's ideas. In other cases, a student's time as a Ph.D. student is over before the thesis is finished because he or she was exploited by having to carry out other work aside from their thesis, or the boss had no time to attend to the explanations produced by the student. In such cases, the student must struggle to survive while writing up.
>
> Few bosses sit down and work with students. Normally, they spend some time during the early days explaining how to do things. After that, the student must carry out the routine tasks. The boss just provides the ideas, if they have them; otherwise, they just make minor corrections. The student spends weeks or months with the monotonous tasks in the laboratory, observatory, or in front of a computer with annoying calculations or simulations that consume a lot of time, or with analytical calculations, or carrying out bibliographical research or whatever. Students closer to an empirical branch of the sciences spend a long time with the instruments. The boss is usually present as well, but only to initially explain to the student how the machine works, or when something

> unusual happens, or there are extraordinary observations unrelated to the usual routine. Meanwhile the boss manages and generates ideas. [...]
>
> However, spending time thinking about one's own ideas, without permission, is something that is really not encouraged by the system; quite the opposite. Initiative is discouraged with arguments such as what is established is established. Workers for science are created instead of thinkers. [...]
>
> What is wrong with this situation, I continue to ask. Mainly, that [it is] industrial (mass-produced) science, rather than creativity being encouraged, and the period of optimum creativity of a scientist is exhausted with these ups and downs. We must take into account that, in the long history of science, the majority of great ideas were produced by young scientists. If young students, who could potentially produce new ideas, are used as slaves (or perhaps it is better to say "science workers"), then perpetuation of old ideas and intellectual stagnation are rife.

Even though doctoral educational and research programs worldwide were founded based on the model of the earlier German-speaking world, they appear to have strayed further and further from the fundamental principles that made the original German-speaking academic programs so successful at cultivating revolutionary scientific innovators.

11.2.4 Average Age for Final Degree

To compare the ages at which people received their final degree for the brightest American scientists and the brightest German-speaking scientists of the same era, one can use data from Nobel Prize winners. Scientists who were educated in the United States and won a Nobel Prize in Physiology or Medicine, Chemistry, or Physics prior to 1991 are listed in Tables 11.10, 11.11, and 11.12 respectively. The ages at which the scientists received their final degrees are shown in the tables.

In order to keep the data set focused on the U.S. educational system, scientists who had some of their training in that system but a significant part of their training outside that system (e.g., Americans such as Irving Langmuir who completed their education in Germany, or German speakers such as Konrad Bloch who completed their education in the U.S. system) are omitted from these tables.

Unless otherwise noted, all of the individuals in these three tables graduated with a Ph.D. As shown in Table 11.10, many of the winners of a Nobel Prize in Physiology or Medicine had an M.D. instead of a Ph.D. As indicated in the tables, two Nobel Prize winners graduated with a final degree that was not a doctorate. As also noted, a few individuals were delayed in receiving their final degree, due to military service, war disruptions, serious illness, or work obligations.

Students could graduate at any time of year, depending on when their doctoral thesis was completed and approved. In most cases only the year of graduation and not the exact date was readily available. In such cases, the graduation was assumed to have occurred on average in the middle of the year, and the students' ages at graduation calculated accordingly. Any errors caused by this assumption should mostly cancel each other out when averages are taken over entire groups of people.

Nobel Prize	Name	Born	Graduated	Age
1933	Thomas Hunt Morgan	25 September 1866	1890	24
1934	George Whipple	28 August 1878	1905	26 (M.D.)
1934	George Minot	2 December 1885	1912	26 (M.D.)
1934	William Murphy	6 February 1892	1922	30 (M.D.)
1943	Edward Doisy	13 November 1893	1920	26
1944	Joseph Erlanger	5 January 1874	1899	25 (M.D.)
1944	Herbert Gasser	5 July 1888	1915	26 (M.D.)
1946	Hermann Muller	21 December 1890	1960	25
1950	Philip Hench	28 February 1896	1920	25 (M.D.)
1950	Edward Kendall	8 March 1886	1910	25
1954	John Enders	10 February 1897	1930	33 (war)
1954	Frederick Robbins	25 August 1916	1940	24 (M.D.)
1954	Thomas Weller	15 June 1915	1940	25 (M.D.)

1989	Norman Ramsey	27 August 1915	1940	24
1990	Jerome Friedman	28 March 1930	1956	26
1990	Henry Kendall	9 December 1926	1955	28

Table 11.12: Ages at final degree for scientists who were educated primarily or entirely in the United States and won a Nobel Prize in Physics prior to 1991.

Table 11.13 summarizes the average ages at graduation from Tables 11.10–11.12 for the U.S. system, excluding those whose education was delayed by war, work, or illness. For comparison, the corresponding average ages from Tables 10.3–10.6 for the German-speaking world are also included. As may be seen, on average those U.S.-educated scientists took approximately two years longer to complete their education than their contemporary counterparts from the German-speaking world. [For related issues, see Dahlgreen 2016.]

Category of people	**Age at graduation from German-speaking world**	**Age at graduation from U.S. system**
Ph.D., Physics Nobel 1901–1990	23.2 years	25.1 years
Ph.D., Chemistry Nobel 1901–1990	22.4 years	24.7 years
Ph.D., Medicine Nobel 1901–1990	23.6 years	25.2 years
M.D., Medicine or Chemistry Nobel	23.8 years	25.0 years
Final degree, all science Nobelists	23.0 years	24.9 years
Ph.D., non-Nobel sample	22.4 years	—
Ph.D., Nobel + non-Nobel sample	22.7 years	25.0 years
M.D., Nobel + non-Nobel sample	23.8 years	25.0 years
Final degree, Nobel + non-Nobel sample	22.9 years	24.9 years

Table 11.13: Ages at final degree for selected scientists educated in German-speaking and U.S. systems.

As a further comparison, the current situation in the U.S. educational system is even worse. For those receiving a doctorate in 2017, the median age at graduation was 31.6 [https://ncses.nsf.gov/pubs/nsf19301/data]. That is nearly a decade older than students who received a Ph.D. from the earlier German-speaking world.

Each increase in the average age at which scientists and engineers receive their final degree means fewer years for their research careers, especially fewer available years when they are youngest, most creative, most energetic, and least distracted by other factors in their lives (family obligations, serving on committees, etc.):

- By this criterion, scientists in the early U.S. research system graduated approximately two years behind their contemporary German-speaking peers, which might be one factor explaining why those U.S. scientists may have created fewer revolutionary innovations per person than their German-speaking peers.

- Yet scientists in the modern U.S. research system graduate approximately 6.5 years behind even those early U.S. scientists, and nearly a decade behind the early German-speaking creators, which might help explain why the modern system may create even fewer revolutionary innovations per person.

The problem is even worse than those numbers indicate. In general, many (though certainly not all) of the German-speaking creators and the early U.S. scientists were able to conduct truly independent research as soon as they obtained their doctoral degrees, if not before. In contrast, scientists who receive a Ph.D. or M.D. in the modern U.S. system typically then have to spend many years following older supervisors' instructions in postdoctoral jobs, residencies, or entry-level positions at corporate or government laboratories. In 2020, the average age at which Ph.D. scientists received their first National Institutes of Health (NIH) research project grant was 43, and the average age at which M.D. scientists received their first NIH research grant was 46 [https://nexus.od.nih.gov/all/2021/11/18/long-term-trends-in-the-age-of-principal-investigators-supported-for-the-first-time-on-nih-r01-awards/]. Thus many German-speaking creators and early U.S. scientists achieved similar independence on average two whole decades in life earlier than scientists in the modern U.S. system.

As discussed in Chapter 12, this data suggests that one way to improve the modern innovation system would be to eliminate redundancies between high school and undergraduate education, streamline the graduate school educational process, greatly lower the average ages at which scientists receive their final degrees and their first financial grants, and give young scientists much more independence during their most energetic and creative years.

11.2.5 Interdisciplinary Approach

A significant fraction of the German-speaking creators were individuals who had demonstrated that they could be productive in multiple scientific fields in Europe (Section 10.2.5), and that continued to be true for many of the German-speaking creators who moved to the United States before, during, or after the Third Reich. Many examples could be cited; here are just a few of the better known cases:

- Hans Bethe was a vigorous force in fields from astrophysics to international politics [Bethe 1991].
- Carl Djerassi not only helped to develop oral contraceptives, new methods for analytical chemistry, and safer pesticides, but also wrote novels and plays that received worldwide recognition [Carr 2009; http://www.djerassi.com].
- Krafft Ehricke made major advances in rocket design, nuclear engineering, orbital mechanics, and planetary science [Freeman 2008].
- George Gamow advanced our knowledge of both the Big Bang and the genetic code [Gino Segrè 2011].
- John von Neumann made major contributions to everything from nuclear weapons design to computers to economics to political policy [Macrae 1992].
- Leo Szilard was responsible for the beginnings of both the Manhattan Project and molecular biology research in the United States [Lanouette and Silard 1992].
- Herbert Wagner developed jet engines, guided missiles, and nuclear engineering projects [p. 4165; Christopher 2013; Constant 1980].
- Fritz Zwicky was known for his exceptional creativity in fields ranging from jet propulsion to astrophysics [John Johnson, Jr., 2019; Stöckli and Müller 2008].

Among the American-born creators who were active during the golden age of the U.S. system, there appear to have been fewer truly interdisciplinary individuals, although there were a few notable cases; for example:

- John Bardeen made Nobel-prize-winning contributions to both transistors and superconductivity [Hoddeson and Daitch 2002].
- Linus Pauling contributed to quantum physics, chemistry, protein structure, DNA research, and international politics [Serafini 1989].
- Simon Ramo was instrumental in national programs ranging from air defense systems to ballistic missiles, and he was as skilled at business and politics as he was at science and engineering [Ramo 1988].

In modern peer-reviewed committee decisions for research grants and academic tenure, very long lists of papers in the same narrow specialty are especially valued, and it is difficult to find examples of revolutionary innovators who are making major contributions in several very different fields. There are probably still some who have survived within the modern system, but the trend seems to be that interdisciplinary creators were most valued, and therefore most prevalent, in the earlier German-speaking world, still in evidence in the 1940s–1960s U.S. system, and increasingly rare in the decades since.

One might object that modern scientific fields have advanced so far that it is no longer feasible for individuals to acquire sufficient multidisciplinary expertise. However, that objection does not seem valid when one examines the enormous knowledge, expertise, and accomplishments of earlier scientists such as John von Neumann or Enrico Fermi, or when one considers that revolutionary innovations in many fields seem to have matured and stagnated at the level that was created by those same interdisciplinary creators. In other words, if those earlier multidisciplinary creators were revived from the dead today, they would probably be able to quickly catch up on the few truly important developments they had missed, and then continue their work in multiple fields. If individuals could be so successful studying and working in multiple disciplines in the twentieth century, modern students should be able to acquire the same breadth and depth of expertise now.

Certainly most scientists and engineers can be rather specialized and still contribute fully to the system. Nonetheless, there is great value if some small but significant fraction of individuals possesses a much broader interdisciplinary expertise. With that broader view of the entire scientific landscape, they can help to:

1. Guide the system toward more revolutionary areas that might otherwise be overlooked by those with only microspecialized views of known areas.

2. Take successful methodologies, discoveries, and inventions from one area and apply them to make advances in a completely different area.

3. Spot areas that for certain fundamental reasons are scientific dead ends.

4. Effectively communicate the state of scientific fields to scientists in other fields, government leaders, business leaders, students, and the general public.

11.2.6 Scientific Leadership and Decision-Making Style

Just as certain high-level scientific managers in the earlier German-speaking world seem to have operated as enlightened despots in identifying and funding promising creators and creations, a large number of enlightened despots appear to have greatly contributed to the successes of the U.S. research system from the 1940s through the 1960s. Without in any way attempting an exhaustive list, this section provides examples illustrating the impact that individual enlightened despots had on the U.S. research system.

Like the earlier German-speaking enlightened despots, these U.S. enlightened despots had different individual styles, various opportunities, and differing levels of success; they were all imperfect in their scientific judgment and/or personal character (some more than others), and most if not all of them made some strong enemies along the way. Nonetheless, also like their earlier German-speaking counterparts, each of these U.S. despots had:

- The strong and direct support of very high authorities (in many cases actually the U.S. President).
- A keen eye for revolutionary innovators and innovations.
- The ability to directly offer steady employment and funding for any innovators and innovations they deemed worthy, by circumventing the much slower and more risk-averse normal bureaucratic processes for application, review, approval, renewal, etc.

Vannevar Bush (1890–1974), shown in Fig. 11.65, may be viewed as the political father of the U.S. research world,[10] just as Friedrich Althoff may be viewed as the political father of the earlier German-speaking research world (p. 2001). Like Althoff, Bush also installed or aided a number of other enlightened despots, such as those shown in the lower half of Fig. 11.65. Bush was an electrical engineering professor and vice president at the Massachusetts Institute of Technology (MIT) as World War II approached and U.S. government funding for R&D was minimal. Bush became president of the Carnegie Institution for Science in Washington, DC (1939–1955), as well as chair and member of the advisory board of the National Advisory Committee for Aeronautics (NACA, the predecessor of NASA, 1938–1948). In 1940 he successfully lobbied President Franklin Roosevelt to create the National Defense Research Committee (NDRC) and Office of Scientific Research and Development (OSRD), which Bush ran until 1947 and in which capacity he reported directly to the President. Bush's NDRC and OSRD were in charge of creating, funding, and managing all military scientific R&D in the United States during these years, including U.S. developments in nuclear fission reactors and weapons, radar systems, proximity fuses, penicillin mass production, and other innovations. After the war, Bush proposed and successfully lobbied for the establishment of the major U.S. government research sponsoring agencies, including the creation of the National Science Foundation, the Atomic Energy Commission (now called the Department of Energy), and the military Research and Development Board (RDB, predecessor of later Department of Defense research sponsoring offices), as well as major expansions of NACA and the National Institutes of Health (NIH). Bush also strongly promoted corporate research while serving on the board of directors for American Telephone and Telegraph (AT&T, 1949–1962), Merck (1949–1962), and other companies.

Vannevar Bush

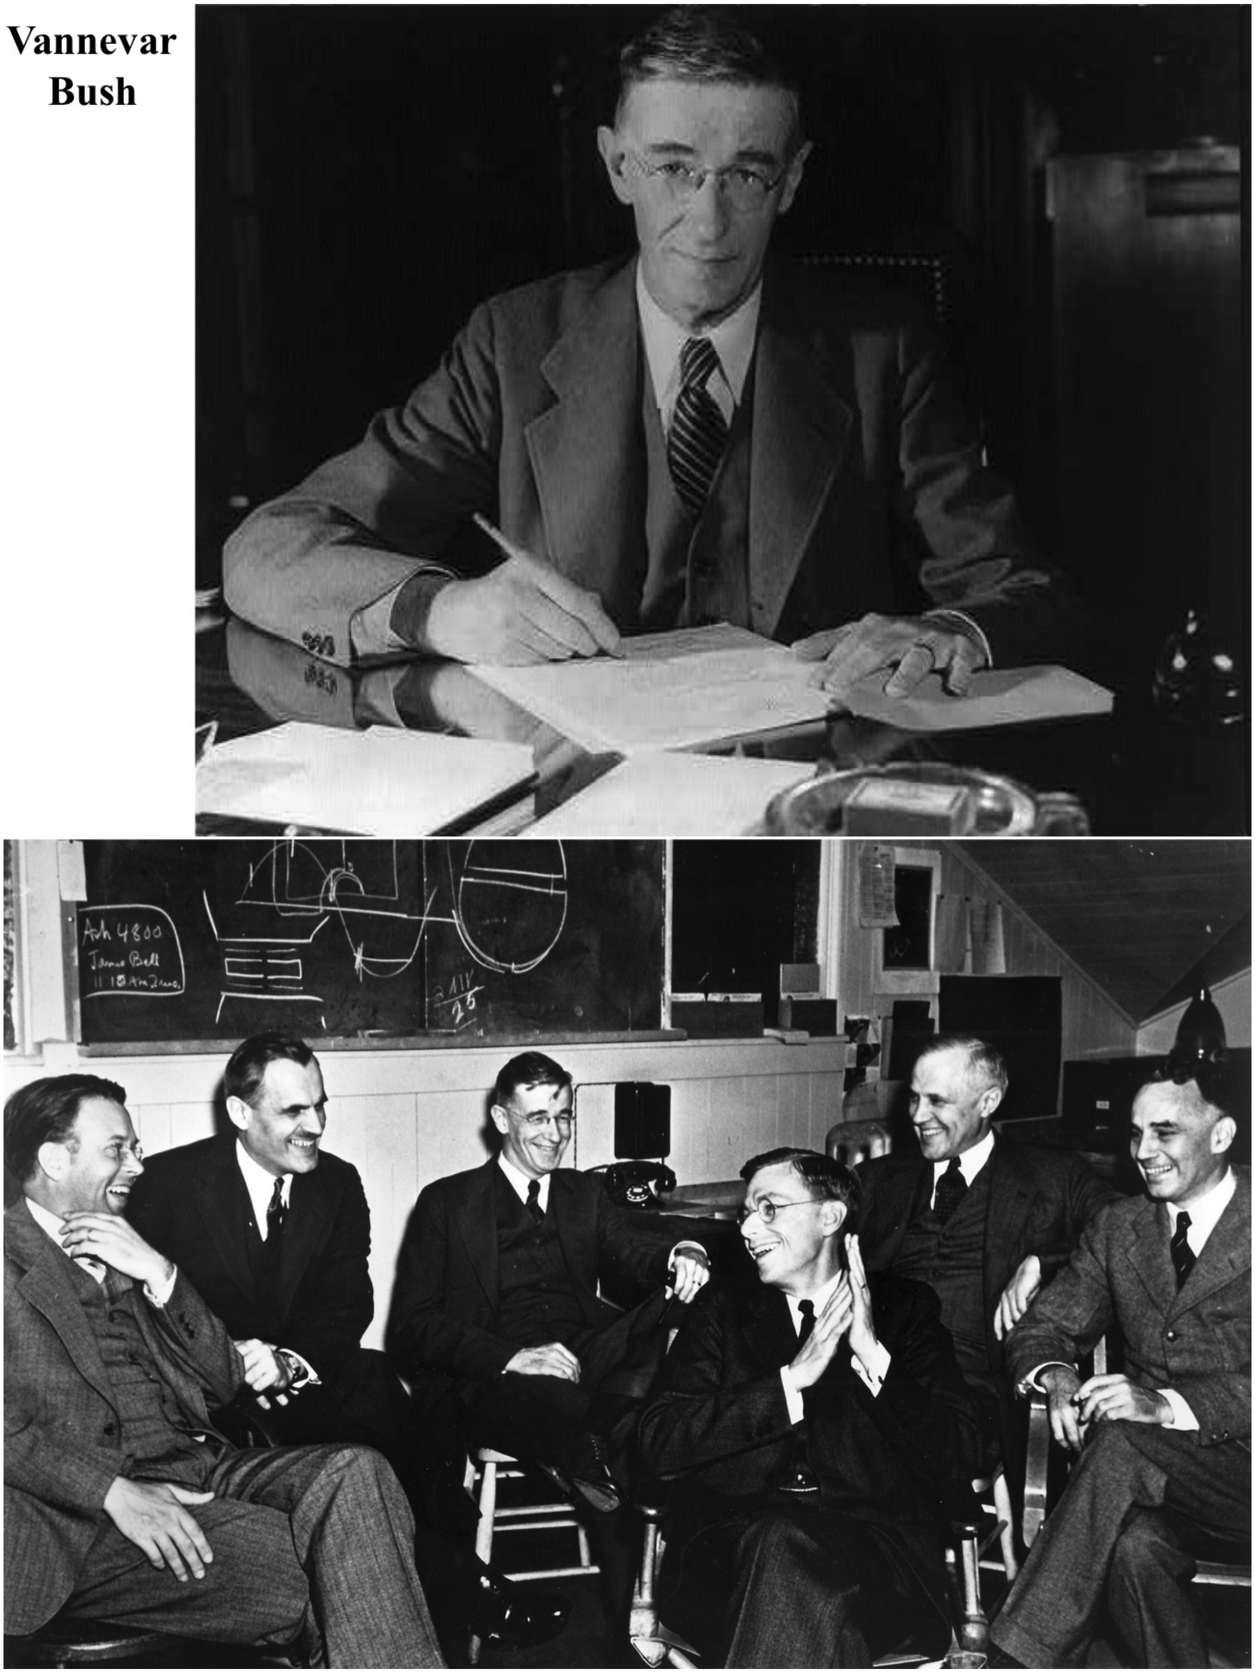

Figure 11.65: Examples of scientific "enlightened despots" who had a large impact on the U.S. system. Above: Vannevar Bush established the entire government-funded research system during and immediately after World War II. Below: March 1940 meeting of Ernest Lawrence, Arthur Compton, Vannevar Bush, James Conant, Karl Compton, and Alfred Loomis (from left to right).

Bush laid out some of his views on scientific innovation in an allegorical essay entitled "The Builders" [Bush 1967, pp. 11–12]:

> The process by which the boundaries of knowledge are advanced, and the structure of organized science is built, is a complex process indeed. It corresponds fairly well with the exploitation of a difficult quarry for its building materials and the fitting of these into an edifice[...]
>
> In these circumstances it is not at all strange that the workers sometimes proceed in erratic ways. There are those who are quite content, given a few tools, to dig away, unearthing odd blocks, piling them up in the view of fellow workers, and apparently not caring whether they fit anywhere or not. Unfortunately there are also those who watch carefully until some industrious group digs out a particularly ornamental block, whereupon they fit it in place with much gusto and bow to the crowd. Some groups do not dig at all, but spend all their time arguing as to the exact arrangement of a cornice or abutment. Some spend all their days trying to pull down a block or two that a rival has put in place. Some, indeed, neither dig nor argue, but go along with the crowd, scratch here and there, and enjoy the scenery. Some sit by and give advice, and some just sit.
>
> On the other hand there are those men of rare vision, who can grasp well in advance just the block that is needed for rapid advance on a section of the edifice to be possible, who can tell by some subtle sense where it will be found, and who have an uncanny skill in cleaning away dross and bringing it surely into the light. These are the master workmen.

Historian G. Pascal Zachary gave an excellent overview of Bush's personality and legacy [Zachary 1997a, pp. 4–5, 7–8]:

> [...] Bush believed Americans should freely give public-spirited experts ultimate authority over the nation's security. He ranked the engineer as first among equals, a sort of super-citizen who could master virtually every activity essential to the smooth functioning of a modern nation. What distinguished the engineer from other experts was his breadth. Bush saw the engineer as a pragmatic polymath; the engineer, he once wrote, "was not primarily a physicist, or a business man, or an inventor but [someone] who would acquire some of the skills and knowledge of each of these and be capable of successfully developing and applying new devices on the grand scale."
>
> This realization that the engineer was the *engine* of 20th-century capitalism qualified Bush as the godfather of high technology and a leading proponent of industrial vitality through innovation, not intrigue. [...] At midcentury, he was among the few who realized the curative power of new ventures. The best way to limit monopoly economic power, he insisted, was through "the advent of small new industrial units, for if these latter have half a chance they can cut rings around the great stodgy concern."
>
> Such contrarian views made Bush a divisive figure. His personality didn't always help either. His philosopher-king aura smacked of arrogance, even meanness to some. He struck his critics as imperious, intimidating and at times even a bully who harbored "a relentless, perhaps insatiable, drive for power." Still he had redeeming qualities. His wit and charm prompted comparisons with the folksy Will Rogers. His intelligence,

> vitality and candor impressed many. He enjoyed a good tussle, refused to back down from anyone and, when opposed, could explode in anger. He rubbed people in authority the wrong way, but he was principled about it. He felt he never angered anyone without good reason. Aware that his penchant for battle cost him good will, he still never shied away from a fight, and he took as much ground as his opponents ceded. "My whole philosophy . . . is very simple," he told a few generals during the war. "If I have any doubt as to whether I am supposed to do a job or not, I do it, and if someone socks me, I lay off." [...]
>
> Acts of importance were the measure of Bush's life, and they are the reason his life deserves study today. His was a political life, wrapped in the enigma of science and invention. An apostle of expertise, he transcended the labels of "liberal" or "conservative" and pursued the progressive ideal of public betterment through the private efforts of people of good will and merit. [...]
>
> In an age of complexity, Bush's habits of mind transcended easy categorization and prefigured the postmodern embrace of contradictions. He was a contrarian, skeptical of easy solutions yet willing to tackle tough problems without a compass. He looked askance at social status based on wealth, but fervently believed that mass opinion should be directed by a "natural aristocracy" of meritorious Americans. He was a pragmatist who thought that knowledge arose from a physical encounter with a stubborn reality. The mathematician Norbert Wiener called him "one of the greatest apparatus men that America has ever seen—he thinks with his hands as well as with his brain." Despite being drenched in a world of particulars, Bush was ultimately a moral thinker whose grand themes were individual self-reliance, democracy with a small *d* and the absolute necessity for thinking men and women to build—with the help of technology—meaningful patterns from the confusing buzz of facts, ideas and emotions that compose the discourse of any era.
>
> Suspicious of big institutions, whether run by public servants, the military or corporations, Bush objected to the pernicious effects of an increasingly bureaucratized society and the potential for mass mediocrity long before such complaints became conventional wisdom. [...]
>
> His great failure and his enduring triumph was his realization that the course of modern history would be shaped by large hierarchical institutions, making plans and settling scores behind closed doors, working best when insulated from public opinion. That these institutions lost their energy and legitimacy as the 20th century waned would not have surprised Bush. Whether overseeing the creation of the atomic bomb or lobbying to fund "pure" research without utilitarian purpose, he believed the beleaguered individual was still of paramount importance.
>
> "The individual to me is everything," he wrote on the eve of World War II. "I would circumscribe him just as little as possible." In the murderous years that followed, he never lost his faith in the power of one.

As Zachary pointed out, a tragic irony is that Bush, who was probably the most powerful enlightened scientific despot in the history of the United States and who empowered or assisted other enlightened despots, helped to set up the key institutions of the U.S. innovation system that ultimately, over the course of the following decades, replaced the individual far-sighted enlightened despots with a faceless bureaucratic system of myopic, risk-averse peer review.

William M. Allen (1900–1985), shown in Fig. 11.66, ran Boeing 1945–1972 when it developed the 707 through 747 jet airliners. As exemplified by those products, he championed major technological steps, large R&D budgets, and long development timelines [Clive Irving 2014; Serling 1992]. *Fortune* magazine named him one of the "10 greatest CEOs of all time" [Collins 2003]:

> "Don't talk too much," Boeing's new chief admonished himself. "Let others talk."
>
> Its planes helped win the war—yet victory in 1945 looked like death for Boeing. Revenues plummeted more than 90% as orders for bombers vanished overnight. And bombers, everyone knew, were what Boeing was all about.
>
> Everyone, that is, but its new leader. An understated lawyer who said he wasn't qualified for the job, Bill Allen never saw Boeing as the bomber company. It was the company whose engineers built amazing flying machines. In 1952 he bet heavily on a new commercial jet, the 707. At the time, Boeing had no business being in the commercial market, or at least that's what potential customers said. ("You make great bombers up there in Seattle. Why don't you stick with that?") Yet Allen's time frames were bigger too. He saw that Boeing could compete by changing the industry. Under his leadership, Boeing built the 707, 727, 737, and 747—four of the most successful bets in industrial history. At a board meeting described by Robert Serling in *Legend & Legacy*, a director said that if the 747 was too big for the market to swallow, Boeing could back out. "Back out?" stiffened Allen. "If the Boeing Aircraft Co. says we will build this airplane, we will build it even if it takes the resources of the entire company." Like today's CEOs, he endured the swarming gnats who think small: short time frames, pennies per share, a narrow purpose. Allen thought bigger—and left a legacy to match.

(Army) Air Force General Henry "Hap" Arnold (1886–1950), shown in Fig. 11.66, was a very strong supporter of developing revolutionary technologies during and after World War II [Henry Arnold 1945, 1949; Bower 1987; Lasby 1971]. He played an especially important role in getting the United States to acquire a large number of creators and creations from the German-speaking world and to support the employment of those innovators and technologies for U.S. military applications. Historian Clarence Lasby described the extent of Arnold's vision [Lasby 1971, pp. 102–103]:

> Henry "Hap" Arnold, Commanding General of the Air Forces, was determined to capitalize on German advances. A stocky, broad-shouldered West Point graduate and former aide to General Billy Mitchell, Arnold had been the most devoted partisan of airpower throughout the 1930's. He was also a visionary, and was fortunate to find a man who appreciated his new concepts for air warfare in Professor Theodore von Kármán, a Hungarian Jew who in 1929 had left the directorship of the Aeronautical Institute of Aachen, Germany, to assume the same position at the Aeronautical Laboratory at Cal Tech. In 1939 Arnold contracted with von Kármán to construct a 40,000-horsepower wind tunnel, the first of its kind, and to develop rockets to assist the takeoff of heavy aircraft. In September 1944 he called upon his ally again, this time to prepare a blueprint for air research for the next twenty to fifty years. When he addressed the scientist's advisory group, he asked them to free their imaginations. "I see a manless Air Force," he said. "I see no excuse for men in fighter planes to shoot down bombers." Unlike the aviators in the Navy, Arnold had no fear of novel weapons. In May 1945 he had sent von Kármán on a special mission to study the Germans' latest developments, and when his own officers proposed the exploitation of the enemy scientists through Overcast, he approved.

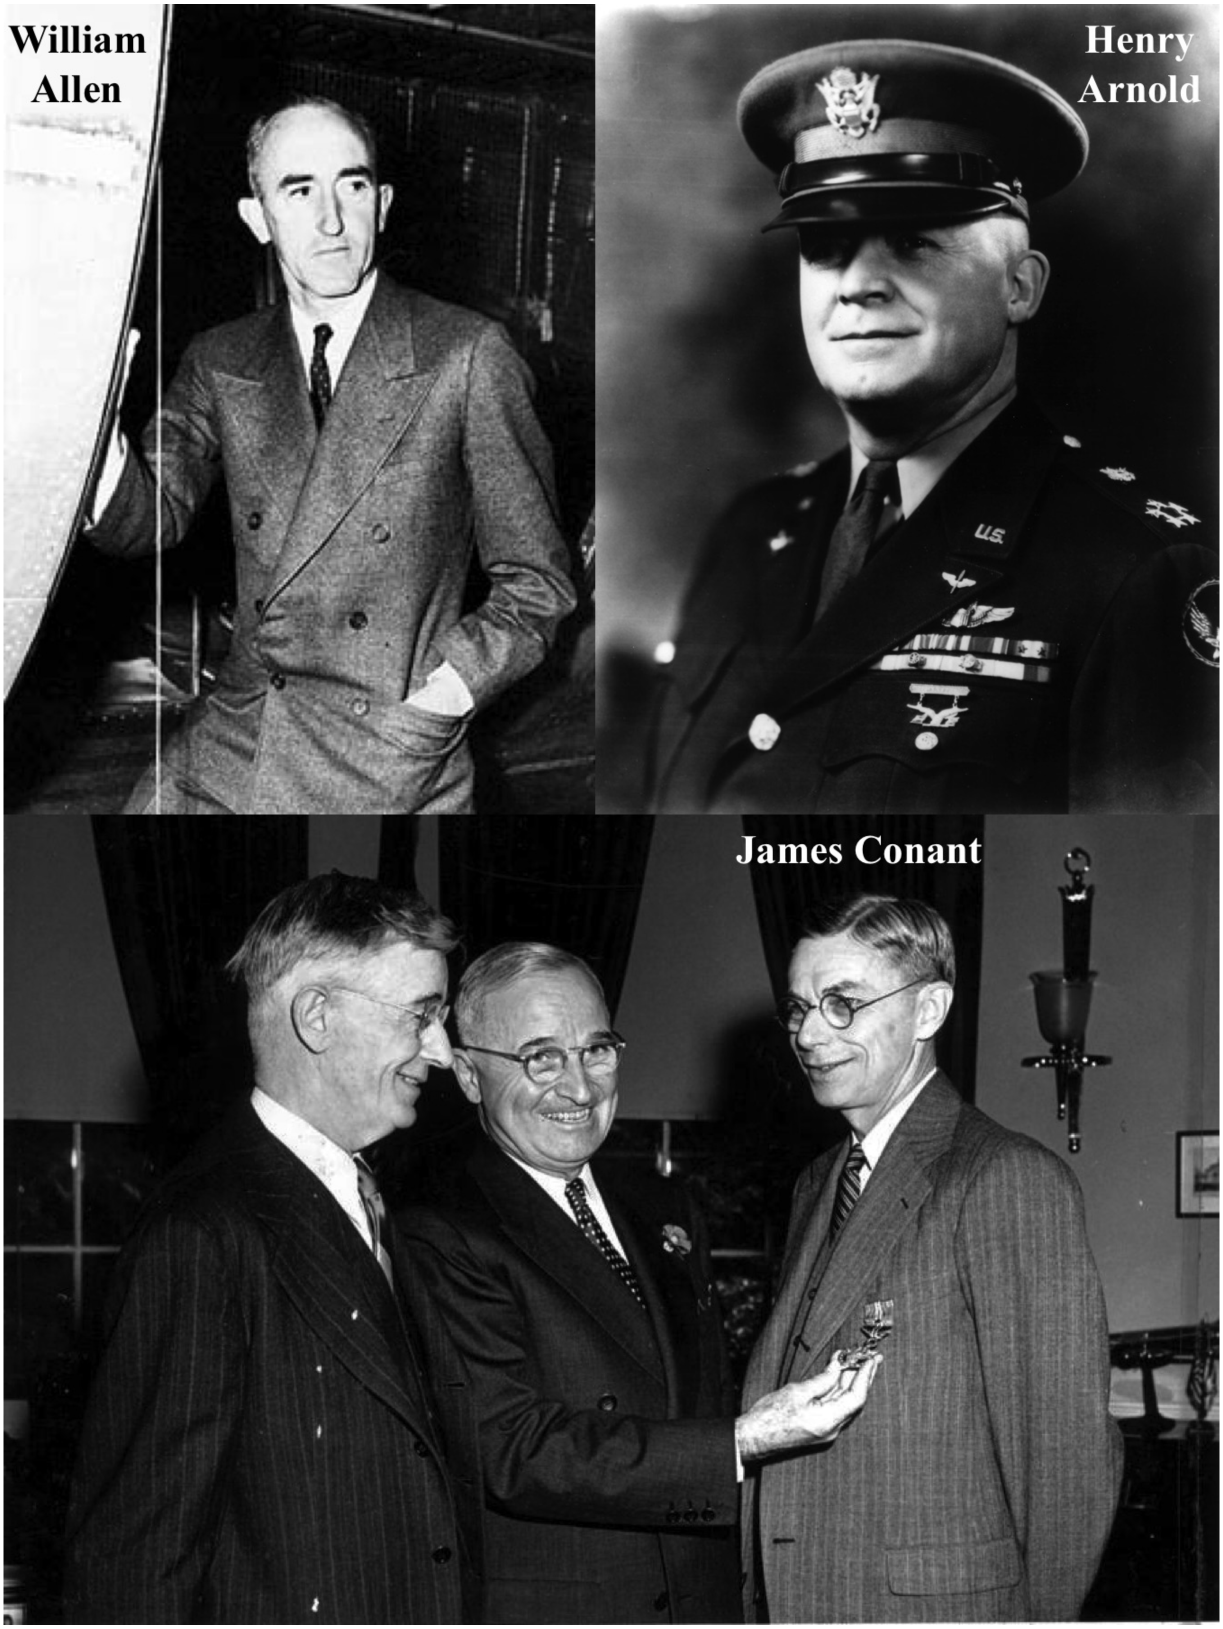

Figure 11.66: More examples of scientific "enlightened despots" who had a very large impact on the U.S. system: William M. Allen ran Boeing 1945–1972 when it developed the 707 through 747 jet airliners. Army Air Forces General Henry Arnold strongly supported revolutionary technologies during and after World War II. James Conant (lower right, with Vannevar Bush and Harry Truman) modernized Harvard University, helped Vannevar Bush run national research during World War II, and was the first U.S. Ambassador to West Germany after the war.

James Conant (1893–1978), shown in Fig. 11.66, modernized Harvard University, helped Vannevar Bush run national research during World War II, and was the first U.S. Ambassador to West Germany after the war [Baxter 1946; James Conant 1970; Jennet Conant 2002, 2017; Zachary 1997a]. According to his obituary [NYT 1978-02-12 p. 1]:

> Dr. Conant led Harvard for 20 years, but the lean, self-effacing six-footer was never in a rut, then or after. He left a brilliant career in chemistry to accept the university's presidency and his resignation in 1953 at the age of 60 marked only the beginning of distinguished roles as diplomat and almost single-handed reformer of, and schoolmaster to, American public education.
>
> As a prelude to his diplomatic service Dr. Conant had served in World War II as a scientific adviser to the Government on the atomic bomb project and was one of those involved in the selection of the target in Japan for the first bomb, which was dropped over Hiroshima Aug. 6, 1945.
>
> Dr. Conant, who spent the major part of his life in the leadership of higher education, perhaps will be best remembered in popular lore as the man who warned of the "social dynamite" accumulating in the cities and who tried to chart a course of improvement for the nation's elementary and secondary schools.
>
> In whatever task he had at hand, he stressed the relevant, the immediate and the practical. He dealt largely in ideas but he liked to see them translated into action, and his habit of sliding back his cuff and glancing at his watch was due more to planning the next step than to impatience.
>
> As an educator Dr. Conant was indifferent to the pressures of politics and consensus and, although he did not seek out controversy, he was unintimidated by it.
>
> He would cling obstinately to his opinions if he thought them right. On the wall of his office at Harvard he kept a framed cartoon with the caption: "Behold the turtle, he makes progress only when his neck is out."

James Conant succinctly summed up his philosophy of scientific management [Jennet Conant 2002, p. vii]:

> To advance scientific knowledge, pick a man of genius, give him money, and let him alone.

Lee DuBridge (1901–1994), shown in Fig. 11.67, directed the MIT Radiation Laboratory 1940–1946 and the California Institute of Technology (Caltech) 1946–1969 [Baxter 1946; Burchard 1948; Jennet Conant 2002; Greenstein 1997; Guerlac 1987]. He facilitated the great wartime successes of the Radiation Laboratory in radar development both by being a strong lobbyist to government for funding and independence for the Laboratory, and also by creating an extraordinarily productive research environment for the scientists working there [Guerlac 1987, p. 297]:

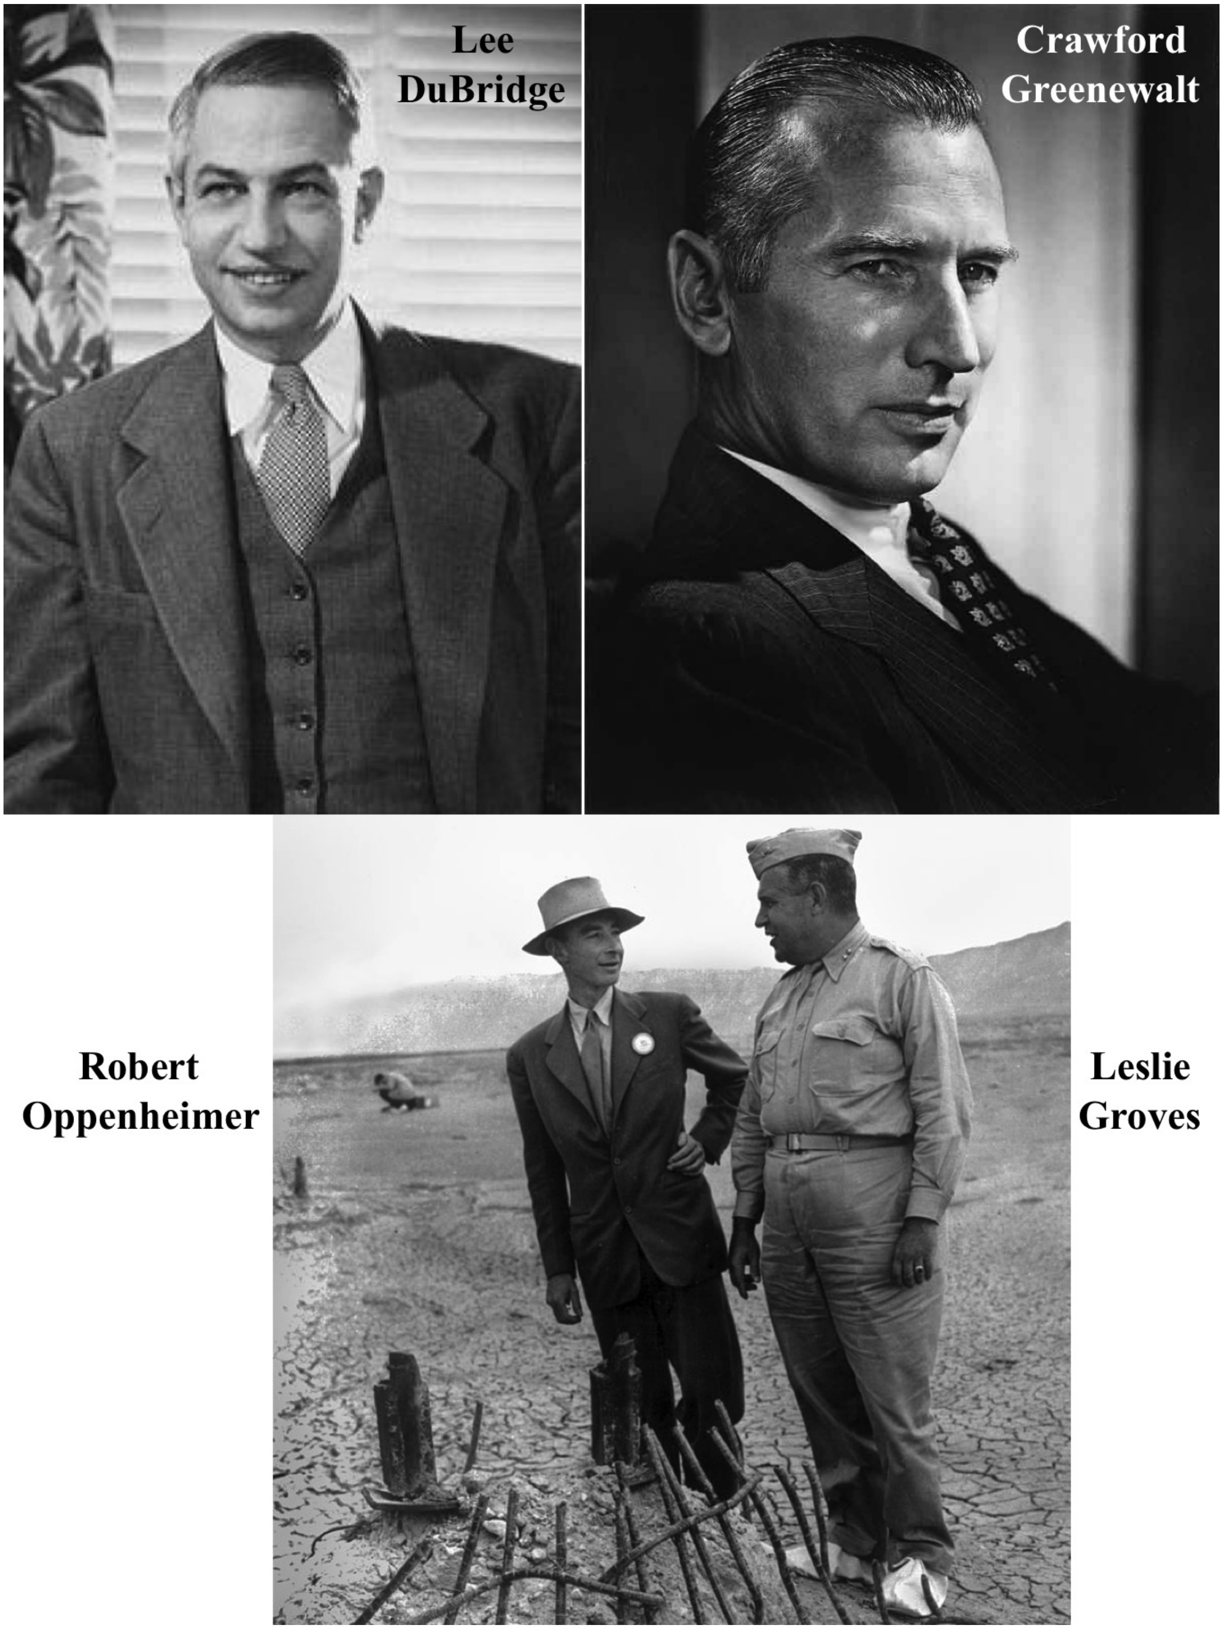
> No full understanding of the administrative eccentricities of the Radiation Laboratory is possible without recognizing that one of its outstanding merits, in the eyes of its own management, was that it was a physicist's world, run for, and as completely as possible by, physicists. Everything was subordinated to producing an environment for research as free and untrammeled as in a university and to preventing research from becoming entangled or impeded by the growing responsibilities thrust upon the organization. [...N]o policy could have been better designed to rid the research man of unwise interference, and to give him unsurpassed opportunities for creative work. The Radiation Laboratory came close to realizing a scientist's dream of a scientific republic, whose only limitation was the supply of scientists.

Jesse Greenstein, a Caltech astronomer, provided more details about DuBridge's personality and accomplishments [Greenstein 1997]:

> In November 1940, under pressure from Lawrence and Loomis, Lee became the founding director of the Radiation Laboratory (RadLab) centered at the Massachusetts Institute of Technology. It did not disband until January 1946. His first helpers, recruited on a crash basis, included a dozen from the nuclear physics community, Alex Allen, Ken Bainbridge, Ed McMillan, I. I. Rabi, Norman Ramsey, Stan Van Voorhis, and Milton White; some of the staff later won Nobel Prizes. By 1945 the lab employed 4,000 scientists and engineers. Lee's style, one that he retained all his life, was one of showing leadership rather than exerting authority. He listened and understood the problems well, but he could be finally decisive. Their first project was to design and build a radar for air interception, which took three months plus a year to mount on the Northrup Black Widow airplanes.
>
> Also designed and built were radar to detect ships and submarines at sea, for night bombing, and to point guns. Over 100 types of microwave radar were created. For each there were training programs, service instructions, and manuals for field maintenance. Many prospective users were trained at MIT. RadLab personnel fanned out over the world to train users and improve field operations. The annual budget reached $50 million. The lab and its products (the theory of high-frequency circuits and the many uses of microwaves) were described in an unclassified twenty-seven-volume series published at the end of the war. [...]
>
> He was in many ways an ideal college president for the twenty-three years he held that office. He was soft-spoken, responsive, and persuasive. He somehow knew how to say "no" and still retain the friendship of a faculty member. He visited faculty offices to ask what was new in a member's field. As senior professor of astronomy I enjoyed Lee's questions as to what had been found recently at Palomar. His broad physical insight gave him quick understanding and he savored what remained puzzling. A further extraordinary ability was to repeat a story, with background and speculation about its future, to a meeting of the Board of Trustees or to the Associates. Sometimes the solution was only money, which he provided at once in small amounts and in large amounts after some effort. Lee spoke very well in public and was under constant pressure to explain Caltech science and education to organizations and the public.

Crawford Greenewalt (1902–1993), shown in Fig. 11.67, helped Du Pont build the plutonium-producing Hanford fission reactors during World War II, and he ran Du Pont 1948–1967 when it introduced its most innovative chemical products [Greenewalt 1959; Hounshell and Smith 1988; Zilg 1984]. In their landmark book on the history of R&D at Du Pont, historians David Hounshell and John Smith, Jr. described Greenewalt's approach [Hounshell and Smith 1988, pp. 358–361]:

> In the twentieth century history of the Du Pont Company, there was perhaps never a more perfect fit between corporate objectives and the career, style, and philosophy of the company's president than during the presidency of Crawford H. Greenewalt. [...]
>
> Starting from virtually no knowledge of fission in October 1942, he rapidly acquired a deep knowledge of reactor physics—deep enough to keep a check on Chicago physicists and not to be cowed by them. [...] Greenewalt so impressed Fermi and Compton that both offered him positions in their postwar research enterprises. [...]
>
> The Manhattan Project's success and the elder du Ponts' continued concerns about family management of the company quickly propelled Greenewalt to the top. [...]
>
> Not long after assuming the presidency, Greenewalt articulated what he believed to be the Du Pont Company's two fundamental principles of growth and development that had served in the past and would continue to govern in the future. Writing in his first annual report as president, Greenewalt noted, "The first of these has been to seek diversification in any chemical field to which it can make a substantial technical contribution." Such a principle meant that "research results have been applied over a wide commercial area." But Du Pont had not done research and development in just any area of the chemical industry. Rather, as Greenewalt stressed, "the second principle has been to direct the Company's research and manufacturing efforts primarily to the large and difficult tasks which inherently require great resources in technical ability and finances." Greenewalt's second principle was a corollary to the one laid down some forty years earlier by Pierre du Pont, who said that the company should always have a few really big, high-risk research projects going because the company stood to benefit both from potentially large payoffs and from keeping an expert force of researchers continually engaged by the company. Greenewalt, the chemical engineer turned executive, envisioned the company developing and managing large, integrated, continuous-process chemical plants that would be the embodiment of his principles. In the future, Du Pont would marshal its resources to do what most other companies could not. From these efforts, "new nylons" would emerge.
>
> The rapid and strong impact that nylon's success had on the Du Pont Company's strategy of growth and its concomitant R&D policies is perhaps best expressed in the phrase "new nylons." By 1945, these two words had become shorthand for the whole paradigmatic shift in Du Pont's research program whereby all the industrial departments, not just the Chemical Department, would undertake fundamental research at the expanded Experimental Station. From a policy level, Crawford Greenewalt's widely circulated report, "Fundamental Research: Definition and Justification," stated the matter succinctly: "We are interested primarily in fundamental research studies which are likely to produce new nylons." [...] Greenewalt often pondered the statistical basis of research and concluded that it was but a form of gambling where the odds were greatly improved through the conduct of fundamental research within a widely diversified company such as Du Pont.



Lee DuBridge
Crawford Greenewalt
Robert Oppenheimer
Leslie Groves

Figure 11.67: More examples of U.S. scientific "enlightened despots": Lee DuBridge directed the MIT Radiation (radar) Laboratory 1940–1946 and the California Institute of Technology 1946–1969. Crawford Greenewalt oversaw the plutonium-producing Hanford fission reactors during World War II and ran Du Pont 1948–1967 when it introduced its most innovative chemical products. Army General Leslie Groves and J. Robert Oppenheimer were the military and scientific directors, respectively, for the WWII U.S. nuclear weapons program, and helped establish the postwar program.

Army General Leslie Groves (1896–1970) and J. Robert Oppenheimer (1904–1967), shown in Fig. 11.67, were the military and scientific directors, respectively, for the WWII U.S. nuclear weapons program, and helped to establish the postwar program.[11]

Colonel Kenneth Nichols, who oversaw the construction and operation of all Manhattan Project facilities under Groves, described Groves [Nichols 1987, p. 108]:

> First, General Groves is the biggest S.O.B. I have ever worked for. He is most demanding. He is most critical. He is always a driver, never a praiser. He is abrasive and sarcastic. He disregards all normal organizational channels. He is extremely intelligent. He has the guts to make timely, difficult decisions. He is the most egotistical man I know. He knows he is right and so sticks by his decision. He abounds with energy and expects everyone to work as hard, or even harder, than he does... if I had to do my part of the atomic bomb project over again and had the privilege of picking my boss, I would pick General Groves.

Nuclear historian and policy analyst Robert Norris described the working relationship between Groves and Oppenheimer [Norris 2002, pp. 242–243]:

> That Oppenheimer and Groves should have worked so well together is really no mystery. Groves saw in Oppenheimer an "overwhelming ambition" that drove him. He understood that Oppenheimer was frustrated and disappointed; that his contributions to theoretical physics had not brought him the recognition he believed he deserved. This project could be his route to immortality. Part of Groves's genius was to entwine other people's ambitions with his own. Groves and Oppenheimer got on so well because each saw in the other the skills and intelligence necessary to fulfill their common goal, the successful use of the bomb in World War II. The bomb in fact would be the route to immortality for both of them.
>
> They treated each other in special ways. Oppenheimer could at times be sarcastic with students or colleagues who could not keep up with his quick mind. Not so with Groves. He patiently answered whatever query the general asked. On Groves's part he treated Oppenheimer delicately, like a fine instrument that needed to be played just right. Groves's normal approach with most of his subordinates was to push them as hard as he could. The pressure was a test to see what they were made of. The more they took, the tougher they were. The good ones would make it through, and those who broke would be transferred, demoted, or replaced. The general saw that this approach would not work with Oppenheimer. Some men if pushed too hard will break.

---

[11] Bird and Sherwin 2005; Jennet Conant 2005; Coster-Mullen 2012; Davis 1968; Groves 1962; Chuck Hansen 1988, 2007; Hawkins et al. 1983; Hoddeson et al. 1993; Jungk 1958; Kelly 2007; Nichols 1987; Norris 2002; Oppenheimer 1984; Bruce Cameron Reed 2015a, 2019; Rhodes 1986, 1995; Serber 1992; Smyth 1945; Sublette 2019.

Army Colonel Ernest Gruhn (1897–1994), shown in Fig. 11.68, the first director of the Joint Intelligence Objectives Agency, was a very strong supporter of developing revolutionary technologies during and after World War II. He played a vital role in getting the United States to import a large number of creators and creations from the German-speaking world and to harness those innovators and technologies for U.S. military applications. In his history of Operation Overcast/Paperclip, Tom Bower wrote [Bower 1987, pp. 137–138]:

> The detailed management of Overcast had by then been transferred from Bissell to Colonel Ernest Gruhn, who had been appointed director of the Joint Intelligence Objectives Agency. Operating from a few rooms in the Munitions Building in Washington, Gruhn and successive directors of JOIA would become passionate advocates of America's need to recruit the Germans and deny them to other powers. More sinisterly, they would deliberately conceal their irregular and unauthorized activities from civilian government departments.

Clarence "Kelly" Johnson (1910–1990), shown in Fig. 11.68, created and ran the Lockheed "Skunk Works" 1943–1975. His operation produced a large number of highly innovative aircraft, including the first U.S. jet fighters such as the P-80 and F-104, the U-2 high-altitude spy plane, the hypersonic SR-71 Blackbird spy plane, and stealth aircraft technology [Johnson and Smith 1989; Pace 2016; Rich 1994, 1995; Tirpak 2018; Yenne 2014]. Ben Rich, Johnson's right-hand man and successor, described Johnson's approach [Rich 1995]:

> Be quick, be quiet, be on time.
>
> That was the credo of Clarence L. (Kelly) Johnson, the aeronautical innovator who founded Lockheed's supersecret "Skunk Works" where he designed the world's fastest and highest-flying aircraft—the SR-71 Blackbird.
>
> Johnson played a leading role in the design of more than forty aircraft and set up a Skunk Works-type operation to develop a Lockheed satellite—the Agena-D—that became the nation's workhorse in space. His achievements over almost six decades captured every major aviation design award and the highest civilian honors of the U.S. government and made him an aerospace legend. [...]
>
> Johnson achieved international recognition for the highly successful Skunk Works operation—"a concentration of a few good people . . . applying the simplest, most straightforward methods possible to develop and produce new products" with minimum overhead and outside oversight—and for his unparalleled management style. [...]
>
> Johnson was known for his hard adherence to principles. On several occasions he turned back development contracts to the U.S. Department of Defense after initial work indicated the proposed aircraft would not be effective, no matter how much money the DoD was willing to provide. [...]
>
> The secret of Kelly Johnson's success was really no secret. He was not only one of the world's foremost designers, but he was an innovative manager who gave people who worked for him challenges to constantly create better products.

> Many of us in the Skunk Works turned down promotions to other Lockheed organizations to stay with Kelly. And uppermost for Kelly was to stay with the Skunk Works. He was offered a company presidency at Lockheed three times—and three times he declined it. "To me," said Kelly, "there was no better job within the corporation than head of Advanced Development Projects—the Skunk Works."
>
> Even when he retired from Lockheed as a corporate senior vice president in 1975, Johnson continued at the Skunk Works as a senior advisor. His influence continues in the Skunk Works. "Our aim," he said, "is to get results cheaper, sooner, and better through application of common sense to tough problems. If it works, don't fix it."
>
> "Reduce reports and other paperwork to a minimum."
>
> "Keep it simple, stupid—KISS—is our constant reminder."
>
> Johnson instinctively knew how to select people for his organization. He knew how to get the most out of the fewest people and how to get the job done—well. He let his managers run their programs with a minimum of interference. He not only gave you the authority but also the responsibility.

Ben Rich gave more information on Johnson and his Skunk Works approach [Rich 1994, p. 7]:

> Most Skunk Workers were handpicked by our just retired leader, Kelly Johnson, one of the reigning barons of American aviation, who first joined Lockheed in 1933 as a twenty-three-year-old fledgling engineer to help design and build the Electra twin-engine transport that helped put the young company and commercial aviation on the map. By the time he retired forty-two years later, Kelly Johnson was recognized as the preeminent aerodynamicist of his time, who had created the fastest and highest-flying military airplanes in history. Inside the Skunk Works, we were a small, intensely cohesive group consisting of about fifty veteran engineers and designers and a hundred or so expert machinists and shop workers. Our forte was building a small number of very technologically advanced airplanes for highly secret missions. What came off our drawing boards provided key strategic and technological advantages for the United States, since our enemies had no way to stop our overflights. Principal customers were the Central Intelligence Agency and the U.S. Air Force; for years we functioned as the CIA's unofficial "toy makers," building for it fabulously successful spy planes, while developing an intimate working partnership with the agency that was unique between government and private industry. Our relations with the Air Force blue-suiters were love-hate—depending on whose heads Kelly was knocking together at any given time to keep the Skunk Works as free as possible from bureaucratic interlopers or the imperious wills of overbearing generals. To his credit Kelly never wavered in his battle for our independence from outside interference, and although more than one Air Force chief of staff over the years had to act as peacemaker between Kelly and some generals of the Air Staff, the proof of our success was that the airplanes we built operated under tight secrecy for eight to ten years before the government even acknowledged their existence.

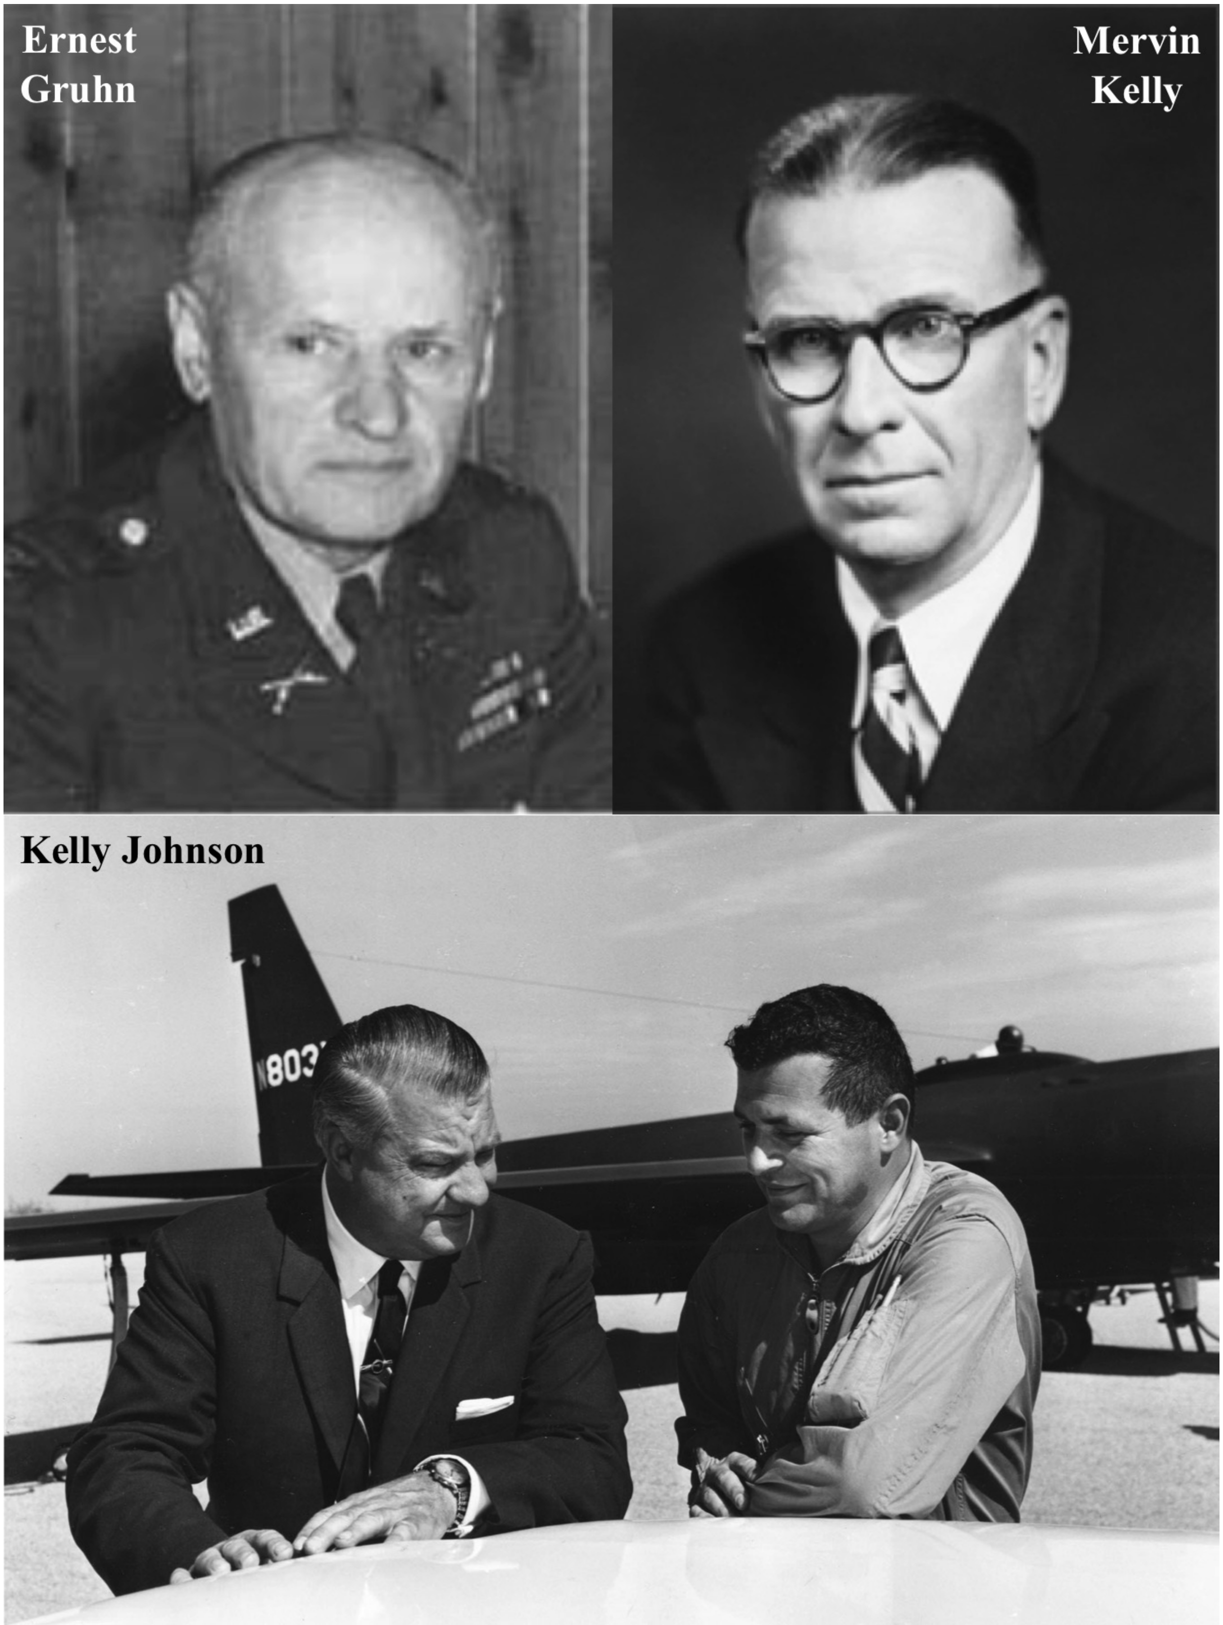


Figure 11.68: More examples of U.S. scientific "enlightened despots": Army Colonel Ernest Gruhn ran the Joint Intelligence Objectives Agency that transferred German scientists and technologies to the United States after World War II. Mervin Kelley created and led breakthrough research programs at AT&T Bell Laboratories 1936–1959. Kelly Johnson (left, with pilot Francis Gary Powers in front of a U-2 spy plane) created and ran the Lockheed "Skunk Works" 1943–1975.

Mervin Kelly (1895–1971), shown in Fig. 11.68, built and led the highly innovative research programs at AT&T Bell Laboratories during the period 1936–1959, occupying positions ranging from director of research to president.[12] John Pierce, a research manager under Kelly at Bell Laboratories, gave a detailed description of Kelly's personality [Pierce 1975]:

> [...] Kelly's greatest contribution lay in creative technical management. It is no more than just to say that Kelly made Bell Laboratories the foremost industrial laboratory in the world. He recognized and inspired good men and good work. He assessed and drove to completion important technical potentialities and opportunities. He shaped and managed a complex organization. And, he inspired the confidence and won the support of the management of AT&T and of the operating telephone companies of the Bell System. As Frederick R. Kappel, former board chairman of AT&T said after Kelly's death:
>
> "He was a great fellow for the Bell System. Mervin was always and forever pushing the operating management, and the heads of AT&T as well, to get on with new things. His aggressiveness got him in a lot of hot arguments, but I always sat back and said, 'Give it to them, Mervin, that's what we need.' Every place needs a fireball or sparkplug, and he was it."
>
> Kelly was not only a sparkplug; he combined determination and showmanship. Twice he submitted his resignation to the president of AT&T, stating that important work at Bell Laboratories was not being adequately funded. In each case, he got the funds. Surely, he was sincere, but he was dramatic as well. [...]
>
> Kelly's greatest accomplishments lay in the Bell Laboratories. He valued talent sincerely, as his warm biographical sketch of C. J. Davisson shows. He wanted, found, appreciated, and encouraged the sort of men who invented the transistor. [...]
>
> When the transistor had been invented, Kelly recognized its worth. As a foreign member of the Swedish Academy of Sciences, he pressed for the award of the Nobel Prize to Bardeen, Brattain, and Shockley. And, for years at Bell Laboratories nothing was any good unless it was "new art" (solid state).
>
> Kelly fostered or launched ambitious programs in nationwide dialing, in automation of maintenance and testing, in microwave communication, in coaxial cable transmission, in transoceanic cables, and in electronic switching. All were timely, and, in the end, all were successful. [...]
>
> After Kelly retired from Bell Laboratories, he acted as a consultant to a number of companies, but chiefly to International Business Machines Incorporated. In this capacity, his energy and enthusiasm were no less than in his leadership of Bell Laboratories, but he wisely realized that his role was that of counsellor to the management, including Thomas Watson, Jr., the chairman of the board, and not that of a boss. According to E. R. Piore, vice president and chief scientist of IBM:
>
> "He traveled to all technical locations in IBM that stretch across this country north and south and east and west and which are located in six countries in Europe. Once in the laboratory, he would [as he used to do at Bell Laboratories] spend time with the people at the bench, stimulating discussion and thinking, constantly evaluating the person and

> the program. Thus he acquired possibly more than any other person, a judgment of men, of programs, and the methods in use. This quality of conversing with the man at the bench, making the man feel at home with Kelly, in no way inhibited him with similar conversations with men up the ladder, including Tom Watson, Jr., and the rest of the group that had oversight over the whole IBM enterprise. Thus he would report to me after his trip and report to Tom Watson also. Mervin was not making a career for himself in IBM. Thus he never fought for his convictions but quietly gave his views—strong, moderate, or negative. This is one reason why his influence was great whether talking to me or to those above me. These conversations dealt with technology, people and management.
>
> "His evaluation and identification of people had a profound effect on their careers. He was after the best technical people, and recommended that they be placed in jobs of ever-increasing responsibility. I would judge that this was his greatest accomplishment in IBM." [...]
>
> Continually pressing for higher achievement, Kelly always prized and promoted ability wherever he found it. Conversely, he was uniformly impatient with mediocrity and almost ruthlessly intolerant of incompetence. [...]

Pierce also provided numerous examples of Mervin Kelly's views on how industrial research and development should be managed [Pierce 1975]:

> Kelly had no doubt as to the place of science and technology in man's life. He wrote: "So completely have they dominated the pattern of our growth that when the man in the street speaks of 'progress,' he usually means scientific and technological progress."
>
> Kelly was equally clear concerning the source of such progress: "Basic research is the foundation on which all technologic advances rest."
>
> What is the source, the generating force behind new ideas? Kelly said: "But with all the needed emphasis on leadership, organization and teamwork, the individual has remained supreme—of paramount importance. It is in the mind of a single person that creative ideas and concepts are born."
>
> Where should basic research be carried out? Kelly noted that " . . . the academic community has been the principal home of basic research for more than a century. . . ." However, he looked toward industry for substantial contributions to research: "The author believes that at least 10 per cent of most research and development budgets can be profitably employed in basic research. Any company that has 50 or more members of professional staff, that will dedicate 10 per cent of them to basic research, can build a strong, productive, and profitable effort." [...]
>
> Using the Bell Laboratories as an example of organized technology, Kelly delineated three areas that preceded the manufacture of complicated technological systems:
>
> "The first includes all of the research and fundamental development. This is our non-scheduled area of work. It provides the reservoir of completely new knowledge, principles, materials, methods, and art that are essential for the development of new communications systems and facilities.

> "The second we call 'systems engineering'. Its major responsibility is the determination of the new specific systems and facilities development projects—their operational and economic objectives and the broad technical plan to be followed. 'Systems engineering' controls and guides the use of the new knowledge obtained from the research and fundamental development programs in the creation of new telephone services and the improvement and lowering of cost of services already established.
>
> "The third encompasses all specific development and design of new systems and facilities. The work is most carefully programmed in conformity with the plan established by the systems engineering studies. Our research and fundamental development programs supply the new knowledge required in meeting the objectives of the new specific developments."
>
> In addition to these three technical areas, Kelly referred to another, the management of buildings, shops, and services:
>
> "The nonscientific duties of management should be minimized for all levels of the research supervision. Through proper organization, direct responsibility for people can be limited to scientists and their aides. Budget preparation, management of shops, services, secretaries and typists, for example, can be done by an intimately associated professional management staff of non-scientists. There should be the very minimum of diversion of the attention of the research leadership and the individual researchers from their scientific programs. This can be accomplished by organizational structures and operations fashioned to free all scientists from nonresearch supervisory duties which, at the same time, provide excellent and economical service in all areas that support the direct scientific endeavor." [...]
>
> Concerning the three functions into which he divided technological endeavor, Kelly made a number of observations. About research, he said:
>
> "Inspired and productive research in industry requires men of the same high quality as is required for distinguished pure research in our universities.
>
> "They must be given freedoms that are equivalent to those of the research man in the university." [...]

Pierce later summarized four aspects of the mid-twentieth-century Bell Laboratories management style that he thought could and should be implemented in other times and places in order to promote revolutionary innovation [Gertner 2012, p. 351]:

> A technically competent management all the way to the top.
>
> Researchers didn't have to raise funds.
>
> Research on a topic or system could be and was supported for years.
>
> Research [on a particular project] could be terminated without damning the researcher.

Before leaving the subject of early management at Bell Laboratories, one should also note (among other examples there) the earlier and partially overlapping contributions of Frank Jewett (1879–1949), who was the first president of Bell Laboratories 1925–1940, chairman of the Bell Laboratories Board of Directors 1940–1944, president of the U.S. National Academy of Sciences 1939–1947, and a member of the National Defense Research Committee during World War II [Buckley 1952].

George W. Merck (1894–1957), shown in Fig. 11.69, ran the U.S. company Merck 1925–1957. His father, Georg(e) Merck, had come to the United States in 1891 to found an American branch of the German pharmaceutical company Merck, but the U.S. government forced the American branch to become a fully independent U.S.-owned company during World War I. George W. Merck succeeded his father as the leader of the American company. During his tenure, he greatly expanded research in a wide variety of areas, and was known for focusing more on producing useful new products than pursuing the highest profits. *Fortune* magazine named him one of the "10 greatest CEOs of all time" [Collins 2003]:

> The Merck & Co. boss didn't worry about Wall Street—and grew profits 50-fold.
>
> Late one afternoon in 1978, Dr. William Campbell did what all great researchers do: He wondered at the data. While testing a new compound to battle parasites in animals, he was struck with the idea that it might be effective against another parasite—one that causes blindness and itching in humans so horrific that some victims have committed suicide. Campbell might have simply scribbled a note in the files and gone to lunch. After all, the potential "customers"—tribal people in remote tropical locations—would have no money to buy it. Undaunted, Campbell penned a memo to his employer, Merck & Co., urging pursuit of the idea. Today 30 million people a year receive Mectizan, the drug inspired by his observation, largely free of charge.
>
> The most exceptional part of the story is that it wasn't an exception. "Medicine is for people, not for the profits," George Merck II declared on the cover of Time in August 1952—a rule his company observed in dispensing streptomycin to Japanese children following World War II. Yet fuzzy-headed moralistic fervor wasn't George Merck. Austere and patrician, he simply believed that the purpose of a corporation is to do something useful, and to do it very well. "And if we have remembered that, the profits have never failed to appear," he explained. "The better we remembered, the larger they have been." It's the mirror image of CEOs whose unhealthy fixations with Wall Street have served neither people nor profits: Merck served shareholders so well precisely because he served others first.

(Army) Air Force General Donald Putt (1905–1988), shown in Fig. 11.69, was a very strong advocate for developing revolutionary technologies after World War II. He played an especially important role in helping the United States acquire a large number of creators and creations from the German-speaking world and employ them for U.S. military applications. For example, Wolfgang Samuel, a retired Air Force colonel and military historian, summarized the contributions of Donald Putt [Samuel 2004, pp. 7–8]:

> Putt determined to go after the intellectual capital of the former Third Reich, the scientists who had designed the jet and rocket planes and other advanced weapons never brought to bear against the Allies simply because the Nazis ran out of time. More than any of his peers, Putt clearly grasped the importance of the German scientist to the technological future of the United States and wanted as many of them as possible, and as soon as possible, brought to Wright Field, the research, development, and test center for the Army Air Forces. There, he thought, the scientists should resume work, making up the technological deficit America had allowed itself to accumulate in the prewar years. [...H]e persisted relentlessly, and in time his efforts were crowned with success.

George W. Merck
Donald Putt
Simon Ramo
Hyman Rickover

Figure 11.69: More examples of U.S. scientific “enlightened despots”: George W. Merck ran the U.S. company Merck 1925–1957. Air Force General Donald Putt recruited German and Austrian scientists at the end of World War II and funded their work in the United States after the war. Simon Ramo directed innovative corporate research for military applications at GE, Hughes Aircraft, and TRW from the 1940s to the 1970s. Navy Admiral Hyman Rickover shepherded the development of fission power for submarines and ships from 1945 onward.

Simon Ramo (1913–2016), shown in Fig. 11.69, ran a very innovative electronics program at General Electric (1936–1946), then created and ran the highly innovative research program at Hughes Aircraft (1946–1953), and then co-founded and managed research at TRW (Thompson Ramo Wooldridge, 1953–1978) [Dyer 1998; Ramo 1980a, 1980b, 1983, 1988, 2005]. Along the way, Ramo reported directly to U.S. presidents and led development of the first U.S. electron microscopes, long-range air defense systems, intercontinental ballistic missiles, interplanetary space probes, and other technologies. The *New York Times* obituary summarized Ramo's accomplishments [NYT 2016-06-30 p. A25]:

> Dr. Ramo, who advised a string of presidents, legislators and cabinet officials on science and technology, was a pioneering force in the aerospace and electronics industries throughout the postwar period.

Navy Admiral Hyman Rickover (1900–1986), shown in Fig. 11.69, shepherded the development of fission power for submarines and ships from 1945 onward [Allen and Polmar 2007; Kruse 2015; Oliver 2014; Rockwell 1995]. *Time* magazine featured Rickover on the cover of its 11 January 1954 issue and described his personality:

> Sharp-tongued Hyman Rickover spurred his men to exhaustion, ripped through red tape, drove contractors into rages. He went on making enemies, but by the end of the war he had won the rank of captain. He had also won a reputation as a man *who gets things done.*

Kevin Kruse described Rickover's methods [Kruse 2015]:

> Rickover was careful to assemble a staff that could build the Navy he envisioned, even though that staff did not always fit the Navy mold. He was the first Navy admiral to bring women on to a submarine (in the 1950s) not because he was a Civil Rights leader but because, as Oliver writes in the book, "we needed brains to make the submarine force successful ... and women possessed half of the available resource."
>
> Rickover went so far as to invent his own selection process, one that bucked Naval practice and policy but was more suited to his needs. Children of the influential were not selected as a matter of course, nor were people with political connections. The Bureau of Personnel did not control the process and the admiral interviewed every new recruit.
>
> Once selected, Rickover allowed his sailors the leeway to try new things and the power to change established practice if a new process was better. He encouraged his staff to do what worked, regardless of preconceived ideas.
>
> Rickover was, himself, an odd choice to change the Navy. He never saw combat, and did not wear the standard uniform at all if he could help it. He was small of stature, a Jewish refugee from Poland and, for all his work altering perceptions, was not the consummate politician top military leaders often are.
>
> He was also the longest-serving naval officer in U.S. history, with 63 years active duty. Which, by itself, says a lot.

Even shortly before the end of his life, Rickover was still creating new programs to nurture young scientists and engineers. In 1983–1984, he helped establish the Center for Excellence in Education and the Research Science Institute, which host 80 high school students at MIT for research mentoring each summer, invite middle- and high-school teachers to participate in research laboratories, and offer other programs to promote scientific innovation [https://www.cee.org/about-us/history/history].

Air Force General Bernard Schriever (1910–2005), shown in Fig. 11.70, was a protégé of General Henry Arnold. Following the path originally laid out by Arnold, Schriever was a strong champion for the development of missiles, rockets, and spacecraft in the U.S. Air Force from his initial appointment to that area in 1954 until his retirement in 1966 [Stephen Johnson 2002; Jacob Neufeld 2004; Sheehan 2009].

Air Force historian Jacob Neufeld gave an excellent overview of Schriever's career and impact [Jacob Neufeld 2004]:

> After the war, Schriever's leadership and accomplishments attracted the attention of senior officers, notably "Hap" Arnold, now the Commanding General of the Army Air Forces. Recognizing his protégé's rare combination of engineering training and operational experience, Arnold assigned Schriever the delicate job of maintaining the close ties forged during the war between the Air Force and nation's leading scientists. Working with the world famous Dr. Theodore von Kármán, chairman of the Scientific Advisory Board (SAB), and with RAND Corporation staffers, Schriever focused on long-range scientific planning. He helped to refine a methodology that matched long-range military requirements with ongoing research and development. Plans were drawn for all major elements of air power—strategic and tactical warfare, air defense, intelligence, and reconnaissance; RAND, the SAB, and university researchers performed the systems analysis studies. As a result, the Air Force did not have to wait for technological change to mature, but could lead and direct it. Put another way, Schriever's staff combined operational requirements with technologies, strategies, and objectives to establish objectives for future systems. "Technology push" thus prevailed over "requirements pull." [...]
>
> In its February 1954 report, the Teapot committee recommended that the Air Force initiate a crash program to produce an ICBM. In May, the Air Force made the Atlas ICBM its top priority and Gardner selected Brigadier General Schriever to head the program.
>
> Activated on 1 July 1954, in Inglewood, a suburb of Los Angeles, Schriever's Western Development Division (WDD), was housed in a former parochial school. It began with twelve officers and three enlisted men, and eventually grew to some 1,500 personnel. Schriever had to create an organization to manage extremely varied and novel science and technology, build facilities for testing and production, integrate the missile systems, fit together the nuclear weapons they would carry, and provide the launching sites, equipment, and ground support necessary to bring the missiles to operational status. Moreover, he had to accomplish all of this within six years and before the Soviets could themselves build, deploy, and target their missiles against the United States! It was a deadly serious, real-life contest of "beat the clock." [...]

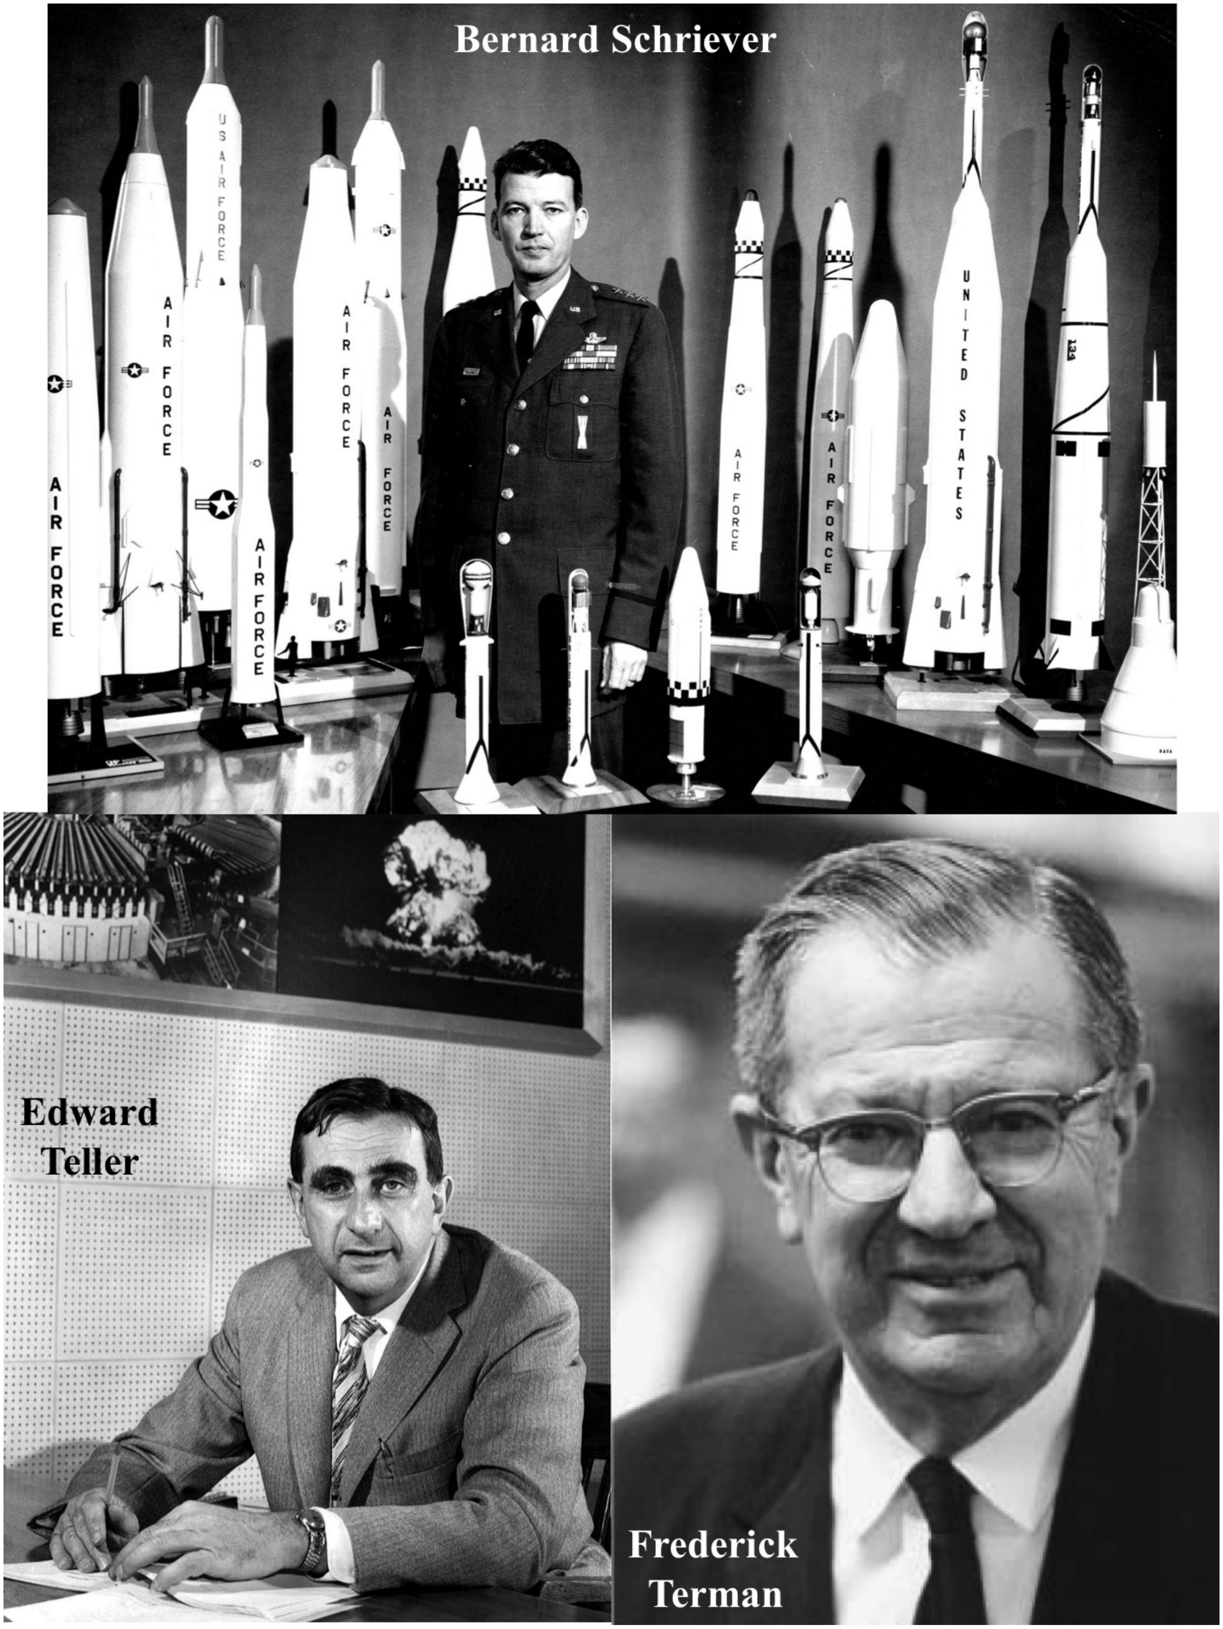
Even as he was preoccupied with acquiring ICBMs and IRBMs, Schriever foresaw the potential of outer space systems and the need to extend the Air Force's interests into the "high frontier." While many of his achievements in the space field remain classified, we can acknowledge his pivotal role in developing the requirements for intelligence and reconnaissance satellites and manned space flight. Schriever's enthusiasm for space exploration tapped his fortitude in sometimes standing up alone to his superiors. Indeed, although some people tried to muzzle him, Schriever never shrank back from what he believed in. [...]

Promoted to four-star rank and head of AFSC General Schriever conceived and effected the consolidation of Air Force technical and logistical efforts into a single organization. More significantly, he transformed the concept of materiel development and acquisition from a functional to a systems approach—the focal point for virtually all-new weapons.

Schriever's role in this transformation was pivotal with respect to his insistence on technologically superior performance standards, adherence to pre-established production schedules, and reliance on cost-control measures. While AFSC commander, he fostered research and oversaw the acquisition of systems that provided strategic deterrence; early detection, warning, and air defense; advanced aircraft and spacecraft designs; command, control, and communication systems; and aerospace medicine. By 1963, AFSC organization employed some 27,000 military and 37,000 civilians, operated an annual budget of over $7 billion (about 40 percent of the USAF's total), and managed eighty major weapons systems. General Schriever defined and institutionalized the acquisition process by demonstrating the interrelationship between technology, strategy, organization, and politics. [...]

In 1963, in response to Air Force Secretary Eugene Zuckert's request for a futuristic study, Schriever launched Project Forecast—one of the most comprehensive long-range assessments ever undertaken of the nation's position in military science and technology. Participants included 40 government agencies, 26 colleges and universities, 70 corporations and 10 non-profit organizations. Published in 1964, this landmark report concluded that rather than leveling off, technology was only beginning its exponential growth. Project Forecast identified several promising areas of exploration that would lead to quantum improvements in air and space weapons: notably in the fields of advanced composite materials, computers, flight design, and propulsion.

For twenty years, from the end of World War II until his retirement in 1966, General Schriever was at the locus of events as the Air Force developed its organization and processes for complex technology. [...] In the Development Planning Office, he helped establish systems analysis as the procedure to set requirements for new technologies.



Bernard Schriever
US AIR FORCE
AIR FORCE
UNITED STATES
Edward Teller
Frederick Terman

Figure 11.70: More examples of U.S. scientific “enlightened despots”: Air Force General Bernard Schriever championed the development of missiles, rockets, and spacecraft 1954–1966. Edward Teller was the scientific head of the U.S. program to develop the hydrogen bomb, and founded and directed the Lawrence Livermore National Laboratory 1958–1975. Frederick Terman was instrumental in establishing Silicon Valley in California 1946–1965.

Edward Teller (1908–2003), shown in Fig. 11.70, one of the German-speaking creators who emigrated to the United States during the Third Reich, was the scientific head of the U.S. program to develop the hydrogen bomb, and founded and helped to direct the Lawrence Livermore National Laboratory 1952–1975 [Blumberg and Panos 1990; Broad 1985, 1992; Teller 1979, 1987, 2001]. While Teller's scientific contributions to the wartime Manhattan Project and postwar H-bomb program are described in Section 8.7, what is especially significant for this section is Teller's political position as an enlightened despot directing major parts of the U.S. research system.

Historian of science István Hargittai summed up Teller's personality [István Hargittai 2010, p. 456]:

> Edward Teller, who survived three exiles, contributed to the way the twentieth century played out on a worldwide stage, even if the extent of his influence is debatable. He had extraordinary willpower and triumphed over many obstacles, including his physical handicap. He waged struggles that many of his peers would have refrained from. He thrust himself into battles that often engulfed him as they would have engulfed anybody. He seemed at times invincible, and he was a dedicated fighter for the containment of communism to an extent few others were. His dedication often appeared as obsession and his schemes as irrational. While he was attempting to save the Free World, he was also trying to impose his will upon it. John A. Wheeler, who was friendly with him throughout his life, noted of him that "he fought obstinately for what he believed in. I may have disagreed with his tactics but never with his goals."

For over half a century and with enormous energy and success, Teller lobbied the government for political and financial support for revolutionary scientific research, while at the same time continually recruiting and mentoring countless young scientists to work on a variety of highly innovative projects. The Lawrence Livermore National Laboratory is the most visible result of those efforts, as described by biographers Stanley Blumberg and Louis Panos [Blumberg and Panos 1990, pp. 211–213]:

> The Lawrence Livermore National Laboratory sits in a valley an hour's drive east of San Francisco. [...]
>
> In 1952, Teller sold Washington on the need for a new weapons lab, and Ernest O. Lawrence sold Teller on Livermore as the place for it. [...]
>
> In time, the laboratory took on distinct signs of Teller's influence. He continued to champion its original purpose as a source of new weapons design and was instrumental in attracting talented young physicists to Livermore. [...]
>
> By 1988 the laboratory employed about 8,000 scientists and other employees on projects costing more than $1 billion a year. Official secrecy shrouds much of their work, inevitably arousing public curiosity concerning the tidbits occasionally dropped about such exotic projects as the X-ray laser, particle beams, kinetic energy, and the like. Lost in the fanfare over these is other, more fundamental work, such as environmental and biomedical research projects seeking answers to vital questions: How do plants respond to chronic low levels of pollutants in the atmosphere? How will chemicals discharged into oceans and streams affect fisheries? How do energy by-products and discharges work their way through the environment and the food chain to affect humans? In looking for the answers, scientists analyze damage to reproductive cells, develop bioassays to detect genetic injury, and do molecular studies on damage and repair of human genes.

Frederick Terman (1900–1982), shown in Fig. 11.70, received his Ph.D. under Vannevar Bush in 1924 and became an electrical engineering professor at Stanford. During World War II he led the Radio Research Laboratory at Harvard University in developing important radar techniques such as radar jammers and chaff countermeasures. After the war, he returned to Stanford as Dean of Engineering and then Provost. During that period (1946–1965), he focused on attracting and supporting talented individuals and new companies to that region, establishing Silicon Valley [Gillmor 2004; Lécuyer 2007; Lowen 1997; Villard 1998].

One of Terman's former students, Stanford electrical engineering professor O. G. Villard, Jr. described Terman's impact [Villard 1998]:

> Frederick Emmons Terman—author, teacher, mentor, university administrator and maker of policy par excellence—was beyond any reasonable doubt responsible for the concentration of economic accomplishment in what has come to be known as California's Silicon Valley, as well as for important innovations in engineering. [...]
>
> [Terman's father] was inventor and co-developer of the Stanford Binet intelligence (or IQ) test[...] This circumstance may well have had an influence in forming Fred Terman's personal philosophy concerning the importance to any organization of truly gifted individuals, who with their followers could be said to form "steeples of excellence."

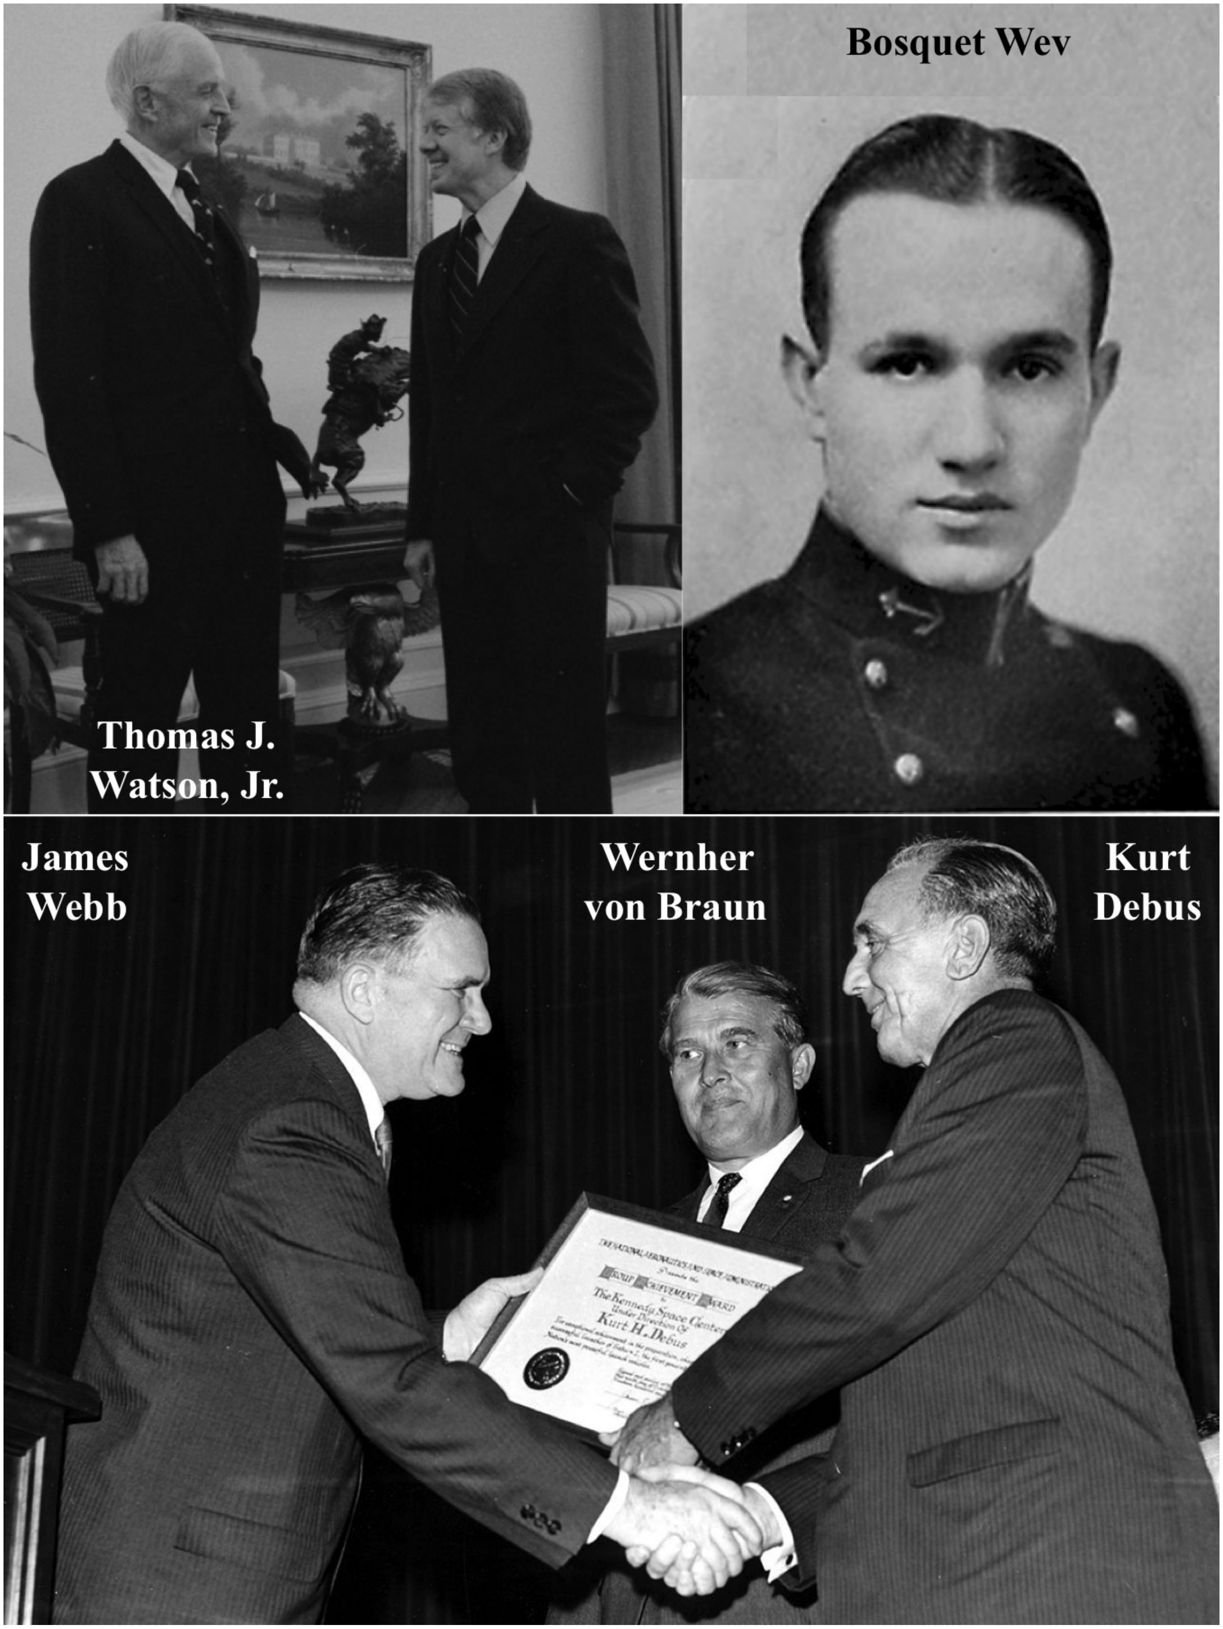
Richard Atkinson, who taught at Stanford under Terman's leadership for nearly 25 years and ultimately became the president of the University of California, described Terman [Gillmor 2004, p. vii]:

> "Father of Silicon Valley": these words seem to leap from the page. Invariably this is the only description now applied to Fred Terman in newspaper and magazine articles. It is not an inaccurate title, but it hardly begins to do justice to the genius that was Frederick Emmons Terman. It is difficult to know where to begin when describing him. He was without doubt a brilliant electrical engineer, a learned scholar who authored groundbreaking textbooks on radio engineering and electronics, an inspiring teacher who kindled the spirit of discovery in his students, and an academic administrator whose devotion to excellence and visionary leadership firmly set a university on the path toward greatness. It was the latter, coupled with the extraordinary depth of his vision that I find the most compelling and enduring of Fred's many accomplishments.

Thomas J. Watson, Jr. (1914–1993), shown in Fig. 11.71, built the innovative research programs at IBM (International Business Machines) during the period 1946–1971, first as vice president and then as president of the company [Thomas Watson 1963, 2000]. The research programs he established greatly advanced computer technologies, microelectronics, and solid state physics applications.

Investors Business Daily wrote [Scott Smith 2016]:

> Watson is credited with moving IBM into the age of electronics at this time, taking it from a manufacturer of adding machines and typewriters to the forefront of the computer industry. In the 1950s, IBM not only invented the first electronic computer and the magnetic hard drive, but designed intercontinental missiles and developed the first artificial intelligence – a machine that could learn from its own experience.
>
> In 1957, IBM revolutionized programming with the FORTRAN language, and the next year it built the SAGE computer to run North American Air Defense. Watson also raised the company's investment in research and development from 3% of annual sales to 6%–9%.
>
> "He invested a lot of money on research and development," said Goldsby, "and it usually paid off."
>
> IBM continued to soar under Watson's leadership in the 1960s, creating the SABRE system for airline reservations, working with NASA on the lunar landing and launching the revolutionary System/360. This offered a range of commercial and scientific uses with the ability to upgrade without having to rewrite applications. Fortune magazine called it "IBM's $5 billion gamble," and it was massively profitable, the major contributor to the 500% increase in company revenue and earnings through the decade.
>
> In this era, IBM also changed its marketing approach from one that only sold hardware, services and software together as one package to one that offered them "unbundled" – a model for later tech companies.
>
> IBM was now the largest computer maker in the world, with 270,000 employees by 1970 and a corporate headquarters in Armonk, N.Y. But the next year, Watson had to step down because of a heart condition. [...]
>
> As the 1990s ended, *Time* magazine named Watson to its list of the "100 most influential people of the 20th century."



Thomas J.
Watson, Jr.
Bosquet Wev
James
Webb
Wernher
von Braun
Kurt
Debus

Figure 11.71: More examples of U.S. scientific "enlightened despots": Thomas J. Watson, Jr. (shown with President Jimmy Carter) built the innovative research programs at IBM during the period 1946–1971. Navy Captain Bosquet Wev (for whom only a very early photo is available) of the Joint Intelligence Objectives Agency strongly advocated for the acquisition of German and Austrian scientists and technologies after World War II. James Webb (lower left, shown with Wernher von Braun and Kurt Debus) ran NASA during its most productive period, 1961–1968.

James Webb (1906–1992), shown with Wernher von Braun and Kurt Debus in Fig. 11.71, ran NASA during its heyday of 1961–1968 [Bizony 2006; Lambright 1995]. He was responsible for all manned and unmanned missions during that time, as well as the Apollo-Saturn technology that had been perfected by the end of his tenure. Webb answered directly to the President, worked with von Braun, Debus, and other German-speaking rocket engineers, and coordinated the vast amount of U.S. industry required to produce all of the necessary hardware. W. Henry Lambright, a professor of political science and public administration at Syracuse University, described Webb's skills [Lambright 1995, pp. 216–217]:

> Management innovation was both a reality and public relations strategy for Webb. Above all, he understood the importance of power: its nurture, use, and loss. With this understanding he showed what a public executive with the right mix of energy, conviction, skill, wide-ranging contacts, and experience can do when conditions are ripe. He was cunning, guileful, manipulative, and hyperbolic—a lot like Lyndon Johnson. If he did not cross the line of administrative accountability, he surely edged up against it. But unlike Johnson, whose orientation was to legislation, Webb cared deeply about the effective administration of public affairs and was able to inspire those under him to new heights. He pushed a vast army of specialists in a common direction, at breakneck speed. A bold risk taker, he confronted pressures from astronauts, the president's science adviser, the air force, the defense secretary, other NASA executives, Congress, media, industry, universities, and many others, and did not flinch. Rather than break under political pressure, he used rhetorical and coalition-building techniques to impose pressures and coopt others. Organizing and reorganizing NASA as circumstances changed, using the resources at his disposal to reward and punish, he kept reign on his internal forces while orchestrating external support. Throughout, he focused on Apollo's goal and what it took to get there.

Space historian Piers Bizony [Bizony 2006, pp. ix–x] added:

> It was a smart operator from North Carolina, James E. Webb, who steered the expansion of NASA from a minor collection of research labs into one of the grandest enterprises the world has ever seen. Aided by a cadre of Southern-born businessmen and politicians, Webb established a colossal network of influence in the service of space. For all its recent setbacks, NASA still commands influence today because of the legacy he created. He knew how to persuade not one, but two presidents in succession to give him what he wanted. [...]
>
> We think of space administrators as dull, colourless bureaucrats. Webb was nothing of the kind. He was a powerful personality, combative, manipulative and driven. You underestimated him at your peril. He was a big, stocky bruiser of a man. When he walked into a room, people knew about it. His broad North Carolina accent and verbose way of speaking sometimes made him come across like a good ol' boy, a 'blabbermouth', as Bobby Kennedy once described him. Yet under all the down-home bluster, one of the sharpest and shrewdest political minds in American history was at work. He took hold of the space age and ran it just the way he wanted.
>
> Webb knew everyone in Washington, and pretty much everyone in the business world. He understood what they wanted, and where his interests and theirs might converge.

> During his leadership of the space efforts in the Kennedy and Lyndon Johnson years, he dispensed largesse, called in favours and occasionally strong-armed people who were foolish enough to oppose him. He was not a man to take 'no' for an answer. His enemies believed he was on a personal crusade to gain power and influence through his running of the space agency. And indeed he was. He was a visionary 'technocrat' whose ambitions stretched far beyond merely landing a man on the moon. By 1964 he held sway over 5 per cent of the entire US federal budget. The potential of that great wealth on the ground was just as important to him as the missions it could pay for in space. Here was a dyed-in-the-wool Democrat idealist who believed in personal honour, moral duty and national responsibility. He had come of age in the Depression years, and worked with Roosevelt during the New Deal era of national reconstruction. He believed passionately in the benefits of good government.

Navy Captain Bosquet Wev (1903–1979) of the Joint Intelligence Objectives Agency (JIOA) was a very strong supporter of developing revolutionary technologies after World War II. He played an especially important role in aiding the United States to acquire a large number of creators and creations from the German-speaking world and to support the employment of those innovators and technologies for U.S. military applications [Bower 1987; Crim 2018; Linda Hunt 1991]. Because Wev and his work were so secretive, the only available photo of him was taken very early in his Navy career and is shown in Fig. 11.71.

In his early book on the Paperclip program, Tom Bower gave a brief description of Wev [Bower 1987, p. 169]:

> Appropriately, with the new era the operation was given a new name: Overcast was replaced by Paperclip. [...]
>
> Equally appropriately, the new era began with the arrival of a new deputy director of JIOA. Captain Bosquet Wev, a conspiciously zealous naval officer, treated his responsibilities at the newly reconstituted JIOA with chauvinistic passion, unwavering obedience, and obsessive secrecy.

Historian Brian Crim described Wev's aims and methods in a much more recent book on Paperclip [Crim 2018, pp. 101–102]:

> Wev regarded the JIOA as a clearing house for intelligence, targeting, and document collection. Paperclip was vital to America's evolving national security concerns, and the more scientists the JIOA could identify, secure, and exfiltrate from Europe before the Soviet Union did the same, the better. Wev's intransigence and dismissive attitude toward rules and regulations reflected the War Department's privileged position, a point he reiterated frequently in meetings.

As shown in Section 10.2.6 and in this section, tremendous numbers of the revolutionary innovations both in the German-speaking research world and in the early decades ($\sim$1940s–1960s) of the U.S. research system can be linked to the enlightened despot scientific management style that was common in those places and times. It is difficult to imagine that all of those revolutionary innovations would have occurred in the modern research system, in which consensus-based bureaucratic competition for limited funding favors very short-term, very low-risk work and eschews new innovations and new innovators.

Indeed, most of the enlightened despots listed in this section retired in the late 1960s or early 1970s, right around the time that the U.S. research system appeared to shift from long-term work on revolutionary innovations to short-term work on incremental progress:

- William Allen retired from Boeing in 1972.
- Vannevar Bush was active on scientific advisory boards until the 1960s.
- James Conant was active on various fronts until the 1960s.
- Lee DuBridge stepped down from Caltech in 1969.
- Crawford Greenewalt left Du Pont in 1967.
- Leslie Groves and Robert Oppenheimer were both active in different ways into the 1960s.
- Kelly Johnson retired from the Lockheed Skunk Works in 1975.
- Mervin Kelly was active until he died in 1971.
- Donald Putt retired from the Air Force in 1957 and from United Technology Center in 1962.
- Simon Ramo stepped down from TRW in 1978.
- Hyman Rickover remained a formidable force through the 1970s.
- Bernard Schriever left the Air Force in 1966.
- Edward Teller retired from managing Lawrence Livermore National Laboratory in 1975.
- Frederick Terman retired from Stanford in 1965.
- Thomas Watson Jr. retired from IBM in 1971.
- James Webb and Wernher von Braun left NASA in 1968 and 1972, respectively.

It is difficult to find examples of enlightened scientific despots who were so numerous or so successful in the United States after that period of time.

This finding suggests that one way to increase the amount of revolutionary innovation in the modern research system would be to find enlightened despots with good judgment, strongly support them from a very high level, and allow them to allocate at least some fraction of the research budget over a sustained period of time to those they consider the most promising innovators and innovations. This approach has been advocated by people such as Pierre Azoulay [Azoulay et al. 2019], Sydney Brenner (p. 2248), and Donald Braben [Braben 2004, 2008, 2014], and is discussed in Chapter 12 .

It is also interesting to note that many enlightened despots who were not strong scientists themselves chose to lead jointly with a very talented scientist. These duos could operate very effectively for years, typically with the less scientific partner carrying most of the burden of advocating for the program “upward” with government officials who were above that program, and the more scientific partner primarily directing “downward” the research of scientists under that program. Examples of these upward/downward management duos included:

- General Henry Arnold and Theodore von Kármán in the U.S. Air Force.
- General Walter Dornberger and Wernher von Braun in Germany.
- James Webb and Wernher von Braun at NASA.
- General Leslie Groves and Robert Oppenheimer in the Manhattan Project.
- Dean Wooldridge and Simon Ramo at Hughes Aircraft and TRW.
- Various pairings of Edward Teller (in either role) over a forty-year period with others such as Ernest Lawrence, Herbert York, and Lowell Wood.

11.2.7 Systems Analysis

Just as systems analysis methods enabled scientists and sponsors in the earlier German-speaking world to explore all possible creations in a given area and identify the best ones, those same methods also guided research and development in the United States, especially during the 1940s–1960s. In fact, the United States directly appropriated the systems analysis methods from the German-speaking world via two routes:

- Importing a wide range of German creations (such as prototype missiles covering all possible categories, or jet engines covering all possible types), which had already been conceived, developed, and categorized by the systems analysis approach.
- Importing German-speaking creators who championed systems analysis methods and employed them in the service of the U.S. government, especially creators such as Theodore von Kármán, Fritz Zwicky, John von Neumann, and Leo Szilard.

A good example of the influence of systems analysis on early U.S. research and development is General Henry Arnold's 12 November 1945 *Third Report of the Commanding General of the Army Air Forces to the Secretary of War* (see p. 5456):

> [...] We must look at the future of aerial warfare in the light of the following considerations:
>
> 1. Aircraft, piloted or pilotless, will move at speeds far beyond the velocity of sound, well over 700 miles per hour.
>
> 2. Improvements in aerodynamics, propulsion, and electronic control will enable unmanned devices to transport means of destruction to targets at distances up to many thousands of miles. However, until such time as guided missiles are so developed that there is no further need for manned aircraft, research in the field of "conventional" aircraft of improved design must be vigorously pursued.
>
> 3. Small amounts of explosive materials, as in atomic bombs, will cause destruction of many square miles.
>
> 4. Defense against present day aircraft may be perfected by target-seeking missiles.
>
> 5. Only aircraft or missiles moving at extreme speeds will be able to penetrate enemy territory protected by such defenses.
>
> 6. A communications system between control center and each individual aircraft will be established.
>
> 7. Location and observation of targets, take-off, navigation and landing of aircraft, and communications will be independent of visibility or weather.
>
> 8. Fully equipped airborne task forces will be able to strike at far distant points and will be totally supplied by air.

> [...] Further, the great unit cost of the atomic bomb means that as nearly as possible every one must be delivered to its intended target. This can be done in one of several ways, all of which involve air power. For example, the following evolution may be suggested:
>
> a. Today, our Army Air Forces are the recognized masters of strategic bombing. Until others can match the present efficiency of our own antiaircraft defenses, we can run a large air operation for the sole purpose of delivering one or two atomic bombs. Our experience in the war suggests that the percentage of failures in an operation of this kind would be low.
>
> b. When improved antiaircraft defenses make this impracticable, we should be ready with a weapon of the general type of the German V-2 rocket, having greatly improved range and precision, and launched from great distances. V-2 is ideally suited to deliver atomic explosives, because effective defense against it would prove extremely difficult.
>
> c. If defenses which can cope even with such a 3,000-mile-per-hour projectile are developed, we must be ready to launch such projectiles nearer the target, to give them a shorter time of flight and make them harder to detect and destroy. We must be ready to launch them from unexpected directions. This can be done from true space ships, capable of operating outside the earth's atmosphere. The design of such a ship is all but practicable today; research will unquestionably bring it into being within the foreseeable future.
>
> [...] Complete dispersal of our cities and moving vital industries underground on a sufficiently large scale would be overwhelmingly expensive. [...]
>
> Although there now appear to be insurmountable difficulties in an active defense against future atomic projectiles similar to the German V-2 but armed with atomic explosives, this condition should only intensify our efforts to discover an effective means of defense. [...]
>
> Jet propulsion is in its infancy despite the fact that this war has evolved six distinct methods of utilizing atmospheric oxygen for propulsion, such as (1) *motorjet*—or reciprocating engine plus ducted fan, (2) *turboprop*—a gas turbine plus propeller, (3) *turbofan*—a gas turbine plus ducted fan, (4) *turbojet*—a gas turbine plus jet, (5) *ramjet*—a continuous jet with compression by aerodynamic ram, and (6) *pulsojet*—or intermittent jet. These new and strange sounding words will be familiar ones in our speech in the near future, and right now they carry more meaning for Americans than any other six words I know.

The above quote, which was clearly heavily influenced by Arnold's chief scientific advisor, Theodore von Kármán (see p. 5438), applied systems analysis first to aerial warfare, then to atomic bomb delivery methods, and finally to aircraft propulsion.

Under the guidance of Theodore von Kármán [Gorn 1992], John von Neumann [Macrae 1992], and others, the entire 1940s–1960s U.S. national defense system was based on systems analysis. All three parts of the nuclear triad (intercontinental jet bombers, land-based intercontinental ballistic missiles, and submarine-launched missiles) were borrowed directly from wartime German programs; see Appendix E for more information. Government-funded think tanks sprang up to apply systems analysis to the remaining details of the defense system; some prominent examples included:

- RAND Corporation (initiated in 1945, finalized in 1948) [Jardini 2013; Kaplan 1991].
- MIT Lincoln Laboratory (founded in 1951) [Grometstein 2011].
- Institute for Defense Analyses (IDA, founded in 1956) [Finkbeiner 2006].
- MITRE Corporation (founded in 1958) [Shearman 2008].
- JASON advisory group (founded in 1959) [Finkbeiner 2006].
- The Analytic Sciences Corporation (TASC, founded in 1966) [http://www.fundinguniverse.com/company-histories/analytic-sciences-corporation-history/].

However, that systems analysis methodology was primarily applied to the U.S. national defense system, not other areas of research and development. By around 1970, the Cold War had relaxed, the national defense system had assumed essentially the form that it still has, and there was little motivation to apply systems analysis to new problems. Moreover, the imported German creations that were steeped in systems analysis (missiles of all possible types, jets of all possible types, etc.) had been developed to a very mature state, and the imported German-speaking masters of systems analysis had mostly retired or died. Thus much of the research performed in the decades since around 1970 has been conducted without the insights that systems analysis could offer both to individual scientists and also to the sponsors of scientific research programs.

11.2.8 Limited Natural Resources

Whereas the earlier German-speaking world was very limited in the natural resources that it possessed on its own lands or that it could import, the United States had a wealth of natural resources on its own territory, and even more that it could import from willing suppliers around the world. As a result, the German-speaking world had a strong incentive to invent revolutionary new synthetic materials and processes, but the United States did not. With the assistance of the U.S. government, American companies commercialized synthetic innovations that had been developed in the German world, ranging from new plastics to food substitutes [Gimbel 1990a]. Unfortunately they do not appear to have made the same proportionally large investments that the German-speaking world had made in creating new generations of revolutionary synthetic products and processes.

Now that the United States and the rest of the world are more concerned about dwindling natural resources and accumulating amounts of greenhouse gases, pollution, and waste, these newfound concerns could potentially be used as strong forces to drive a large amount of fresh innovation for synthetic and/or recycled materials.

11.2.9 International Rivalry

Just as military and industrial competition with other countries was a strong driver of innovation in the German-speaking world throughout the entire period 1800–1945 (Fig. 10.15), international competition also strongly motivated innovation in the United States during the 1940s, 1950s, and 1960s (Fig. 11.72).

During World War II, political and military leaders in the United States were deeply concerned about German domination in Europe and German development of revolutionary new technologies such as nuclear weapons, long-range rockets, and jets that could entrench or further spread that domination. As a result, they strongly supported Vannevar Bush's new innovation system, as discussed in Section 11.2.6. Large numbers of immigrant German-speaking scientists and American scientists were rapidly mobilized in the United States to develop nuclear weapons, perfect radar systems, mass-produce penicillin, and accomplish other feats.

Before World War II had even ended, the United States had started to turn its attention to the coming Cold War with the Soviet Union. In 1945, the United States scrambled to extract as many creators, creations, and resources as possible from the former German Reich before those could fall into Soviet hands, although a large fraction did nonetheless. From 1945 onward, the United States was in a race to adopt and perfect as many German-created military technologies as possible, or to develop new ones, before the Soviet Union could do the same. Among the revolutionary technologies that were fielded were improved nuclear weapons, jet fighters and bombers, ground-to-air and air-to-air missiles and smart bombs, advanced air defense networks, nuclear submarines and nuclear aircraft carriers, intermediate range and intercontinental ballistic missiles, nerve gases, and biological warfare agents. Those technologies were arrayed against their Soviet counterparts throughout the Cold War standoff, and some of them were tested on the battlefield in proxy wars between the two superpowers such as those in Korea and Vietnam. In addition to direct military competition, the United States and the Soviet Union also engaged in the space race as an alternative way to display their prowess with closely military-related technologies to each other and to the rest of the world. Buttressing all of those Cold War programs (and heavily subsidized by them) were rapid industrial developments in aerospace technologies, microelectronics, nuclear power, chemical engineering, biomedical research, and other areas.

The journalist David Beers, who grew up surrounded by his father's Cold-War research at Lockheed, described the enormous impact on research and development [Beers 1996, pp. 29–31]:

> It was the government mobilizing and funding technology with a zeal that would burn even hotter once LBJ and John F. Kennedy rode their *Sputnik* scare strategy to the White House in 1960.
>
> It was the state commanding, in a sense, that not only technology but *places* come into being.
>
> Blue sky metropolises, nurtured by federal dollars, would be commanded to rise out of orange groves and scrublands and prairies and deserts and other former boondocks to industrial America. The money would flow to the Northwest of Boeing, to the Texas of Bell Aviation and Mission Control, to the Rocky Mountains of the North American

> Air Defense Command, to the Florida of Martin-Marietta and Cape Canaveral, to the Alabama of Wernher von Braun's U.S. Army Redstone rocket works. [...]
>
> The money would go, as well, to certain centers of technological innovation, the realms, for example, of Boston's MIT and Pasadena's CalTech, universities that made a specialty of military contracts. A basic rule of thumb is that the money flowed to where life could be made affordably good for the blue sky professional and family. [...]
>
> The biggest of them all, of course, was and is Southern California, home to Aerojet and Convair and Ford Aerospace and Hughes and Litton and Lear Siegler and McDonnell-Douglas and Northrop and Rockwell and RAND and TRW and the United States Air Force Space Division and all the hundreds of subcontractors that serve them as well as many key military bases and universities. The San Fernando Valley of Southern California is home as well to Lockheed, and a time came in the late 1950s when Lockheed was commanded to build an answer to *Sputnik*.

However, the Cold War competition dramatically slowed around 1970. After beating the United States to launch the first satellite and the first person in Earth orbit, the Soviet Union lost the moon race when the United States landed the first people on the moon on 20 July 1969; the Soviet Union then cancelled its own manned lunar program and chose not to continue the space race toward even grander goals. With no further competition, the United States discontinued its advanced space program after only six manned lunar landings and billions of dollars spent to develop those technologies, and has only sent astronauts to low Earth orbit with much less capable rockets in the many decades since then.

At almost the same time, the Strategic Arms Limitation Talks (SALT) between the United States and the Soviet Union began in November 1969, effectively marking the end of the fierce competition to develop ever more powerful weapons and delivery systems for them. In general, Soviet Premier Leonid Brezhnev and his successors were significantly less militarily aggressive than Joseph Stalin and Nikita Khrushchev had been. With greatly decreased competition from the Soviet Union, and no other serious rivals in sight, beginning around 1970 the U.S. government started to lose interest in rapid and revolutionary innovation, and its research and development system and industries tended to follow suit.[13]

David Beers wrote about the dramatic shift that he observed in 1970 [Beers 1996, pp. 132–133]:

> "This," President Nixon declared of the lunar landing, "is the greatest week since the beginning of the world, the creation." My tribe, certainly, assumed Apollo's success would secure our dominance. Having been placed in charge of the future, we had delivered as promised a man on the moon on television. As scripted by our tribe's father, Wernher von Braun, the moon shot was to be but a way station on the path to Mars, a warm-up for the building and launching of a "flotilla" of manned spaceships to the red planet.

---

[13] The United States did feel some sense of economic and technological rivalry with Japan during the 1980s, but that was nowhere near as strong or as sustained as the military rivalry with the Soviet Union had been, and therefore was much less motivational for the U.S. innovation system [LaFeber 1997].

> Yet almost at the moment *Eagle* landed, blue sky icons seemed to lose their mojo powers. Environmentalists, utterly unmoved by the sleek loveliness of the SST [supersonic transport], painted it loud and rude, shot it down. The B-70 superbomber program had already crashed in Congress as the antiwar movement challenged the notion that the Pentagon, NASA, or any state authority should be the revered and unchallenged steward of a people's imagination about the future. Few (except for my tribe) took seriously Vice President Agnew's call for a Mars mission. [...]
>
> One year after the greatest week since the beginning of the world, a slowing in weapons spending, coinciding with a slump in commercial jet sales, caused mass aerospace layoffs across the country. [...]
>
> That was a time when some of my father's peers went from designing satellites to perfecting alloy backpack frames (surely Dad hadn't been a compatriot of Neil Armstrong's only to make camping gear!) I remember, while watching the Jetsons suburbanize the Milky Way on TV, reading newspaper stories about out-of-work Lockheed men killing themselves.
>
> That was a time when the tribe clung to hubris nevertheless. One year after the greatest week in the history of the world, members of the blue sky tribe convened the West Coast's First Aerospace Congress to take up the issue of where next to apply the methods used to conquer the moon. Let us now turn aerospace engineers loose, speakers urged, on the problems of pollution, crime, urban blight, racism, poverty. Let us fix society with systems engineering. It fell to Vernon L. Grose, vice president of Tustin Institute of Technology in Santa Barbara, to counsel some caution.

Any remaining Cold War motivation that could drive revolutionary scientific innovation was lost when the Soviet Union disintegrated in 1991. By the time military or economic threats from Islamic terrorism, China, and a resurgent Russia became apparent in the 2000s, the U.S. government was too distracted by bitter internal political battles, and the U.S. research and development system had become too dysfunctional and calcified in the intervening several decades, to seriously rise up to properly deal with any new international innovation challenges.

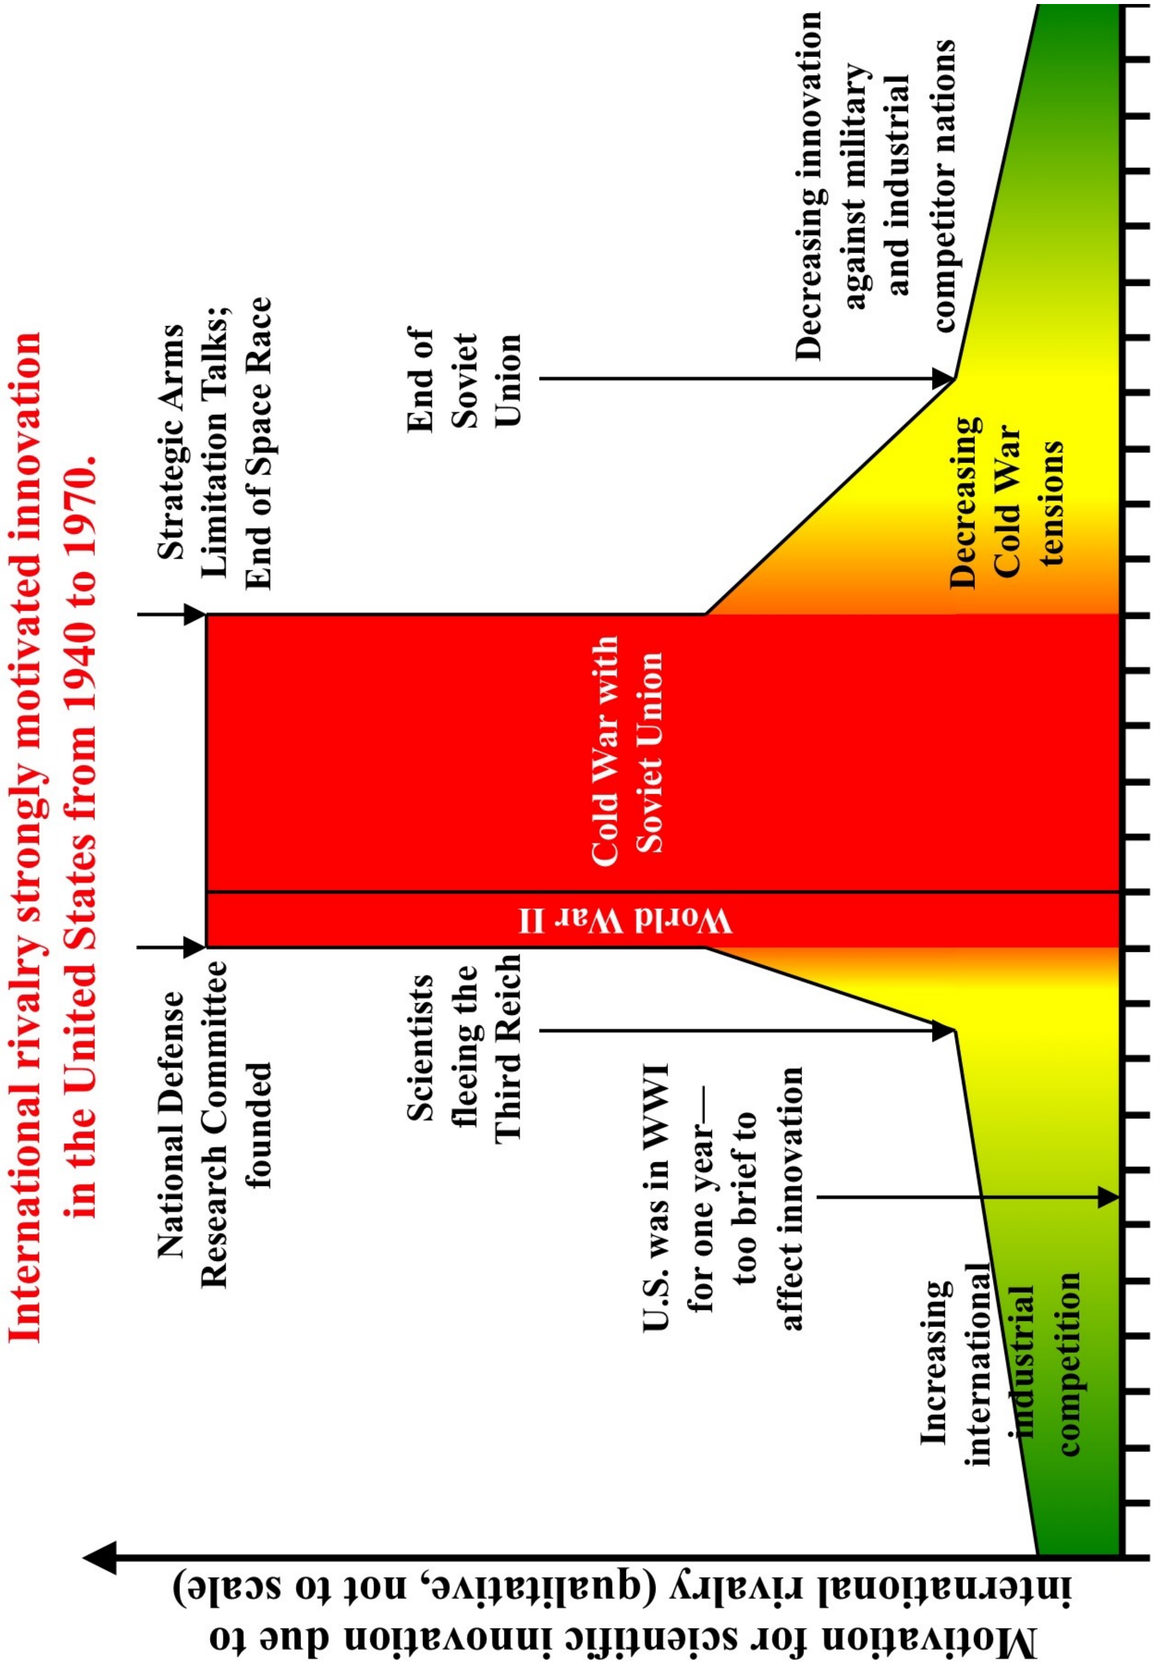


Figure 11.72: International rivalry strongly motivated innovation in the United States from 1940 to 1970.

11.2.10 Industrial Unity of Purpose

Paradoxically, competition between companies can decrease the incentive for innovation, rather than increase it, as shown in Fig. 11.73. Bell Laboratories developed transistors but other companies made fortunes based on that technology [Riordan and Hoddeson 1997]. Hughes Aircraft publicly announced the first laser yet it was other companies that profited by producing and selling lasers [Bromberg 1991]. IBM and Xerox PARC created versatile computers, but lost out when such computers were mass-produced by other companies like Apple and Dell [Isaacson 2014]. Apple developed the iPhone yet lost most of its market share to other companies that rapidly produced similar smart phones [Isaacson 2011]. Pharmaceutical companies have spent billions of dollars to develop new drugs, only to have their patents expire within just a few years after the lengthy drug development and approval process, allowing other companies to manufacture generic versions of those drugs [Alberts 2014; Begley 2009; Hsueh 2015; Mittra 2009; O'Neill 2012].

As a result of this historical pattern, modern companies have learned that it is much more lucrative not to innovate. It is much less profitable to invest a large amount of money in developing an innovative new product that is rapidly copied by competitors, and much more profitable not to invest in research and simply to copy innovations that are developed by someone else.

In the German-speaking world from around 1800 to 1945, these negative forces of competition among domestic companies were counteracted by the much greater sense of competition with foreign governments and industries (Section 10.2.10). The leaders of different German-speaking companies were united by a common sense of purpose, such as beating industrial competition from the United Kingdom or trying to win World Wars I and II. That industrial unity of purpose was cultivated and rewarded by the federal government.

Similarly, from the 1940s to the 1960s, U.S. companies received a much stronger positive incentive for innovation from foreign military competition, first with Germany and then with the Soviet Union, than any domestic negative incentive against innovation. As with the earlier German model, this industrial unity of purpose was nurtured and even dictated by the federal government. Throughout World War II, the Cold War, and the space race, the U.S. government invited bids from companies to develop revolutionary technologies, selectively funded those companies with the most attractive bids, and stipulated when and how companies would collaborate with each other when different parts of a system would be built by different companies (Fig. 11.74).

With the end of the space race and the easing of the Cold War around 1970, there was no longer strong incentive for this industrial unity of purpose, either from the U.S. government or from foreign competition. Companies were left to pursue their individual best economic interests using their own strategies. After a few very public examples (such as those cited above) that it was much more lucrative to take advantage of other companies' innovations than to invest in creating their own innovations, companies fell into a pattern that emphasized very short term, very low risk, very lucrative products. That pattern has continued to the present day.

**Without enough government protection,
companies that invested in developing innovative products
lost most of the market share to other companies
that simply copied those products.**

Transistors

Lasers

Pharmaceuticals

5 Ampoules 2 ml
Valium 10
ROCHE
10 mg
Valium – Trade Mark

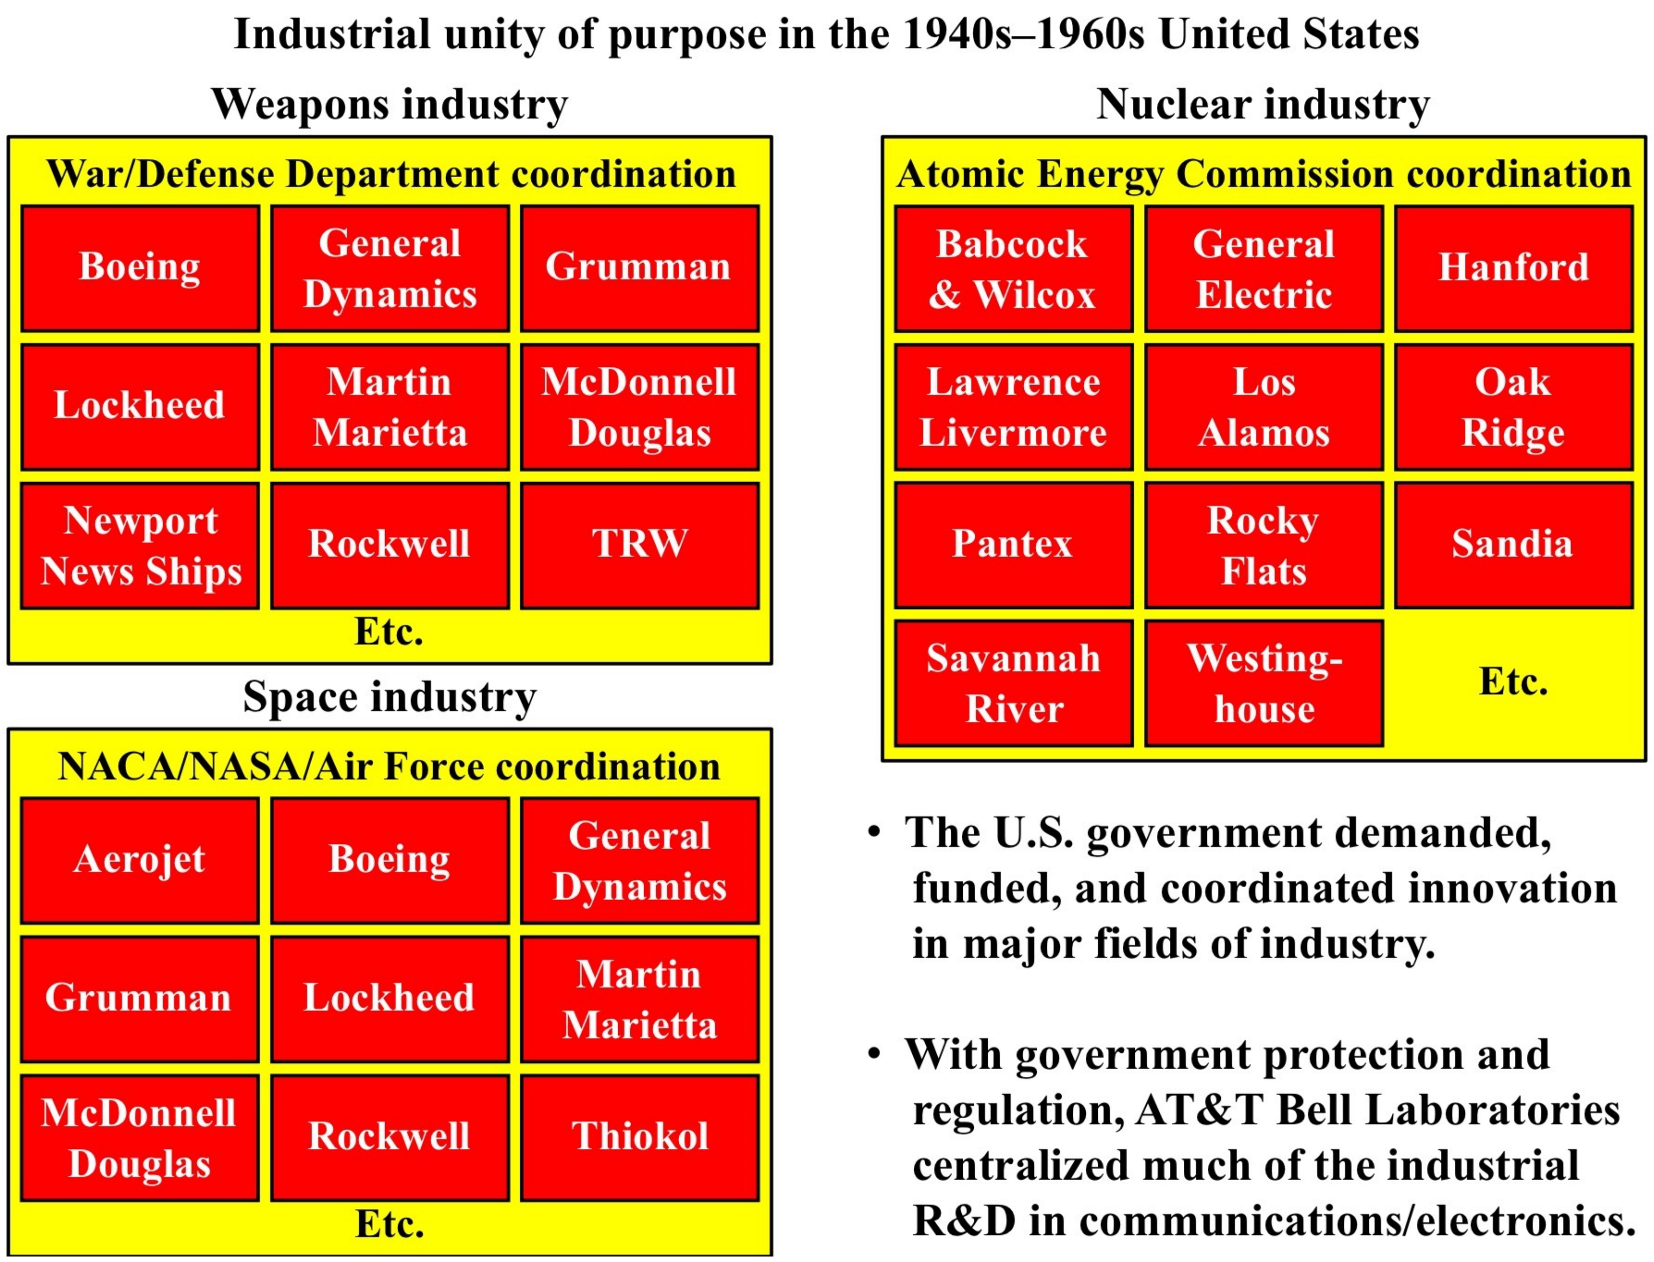
Personal computers

Smartphones

Companies should view very innovative, longer-term R&D as:

- **A worthwhile investment in staying ahead of competitors.**
- **Not a financial liability whose resulting products could be copied by competitors that did not fund their own R&D.**

Figure 11.73: Without enough government protection, companies that invested in developing innovative products lost most of the market share to other companies that simply copied those products, creating a strong disincentive for companies to fund R&D.



Industrial unity of purpose in the 1940s–1960s United States

Rocky Flats
Sandia
Savannah River
Westinghouse
Etc.

- The U.S. government demanded, funded, and coordinated innovation in major fields of industry.
- With government protection and regulation, AT&T Bell Laboratories centralized much of the industrial R&D in communications/electronics.

Figure 11.74: In the United States from 1940 to 1970, companies were less afraid of losing their innovations to each other than of losing to foreign countries, strongly motivating them to innovate (with strong support and coordination by government agencies).

Another strong incentive that the U.S. government could use to alter and unify corporate behavior is taxes. U.S. corporate tax rates were extremely low prior to 1940, high during the 1940s–1960s, and then lower from the 1970s onward, as shown in Fig. 11.75. The high corporate tax rates during the 1940s–1960s were a strong incentive for executives to reinvest most of their company's income in research and development, infrastructure, and employees instead of trying to remove it from the company as cash profits and lose much of it. When those tax rates began to seriously decline from the 1970s onward, the culture of U.S. companies altered dramatically. Research and development programs were downsized or eliminated, U.S.-based laboratories and manufacturing facilities were neglected or closed and outsourced overseas, employees were considered easily replaceable and treated poorly, and more and more of the income generated by large corporate organizations was channeled to fewer and fewer people in those organizations. After those trends have continued for over half a century, the United States has reached a point where many of the largest companies pay no taxes at all on billions of dollars in profit [NYT 2021-04-02] and there are disastrous effects on revolutionary scientific innovation (Sections 1.1 and 11.3.1) and society in general.

Simon Ramo, cofounder of TRW, described how U.S. companies began to view R&D as more of a burden than an opportunity beginning in the 1970s—see p. 52.

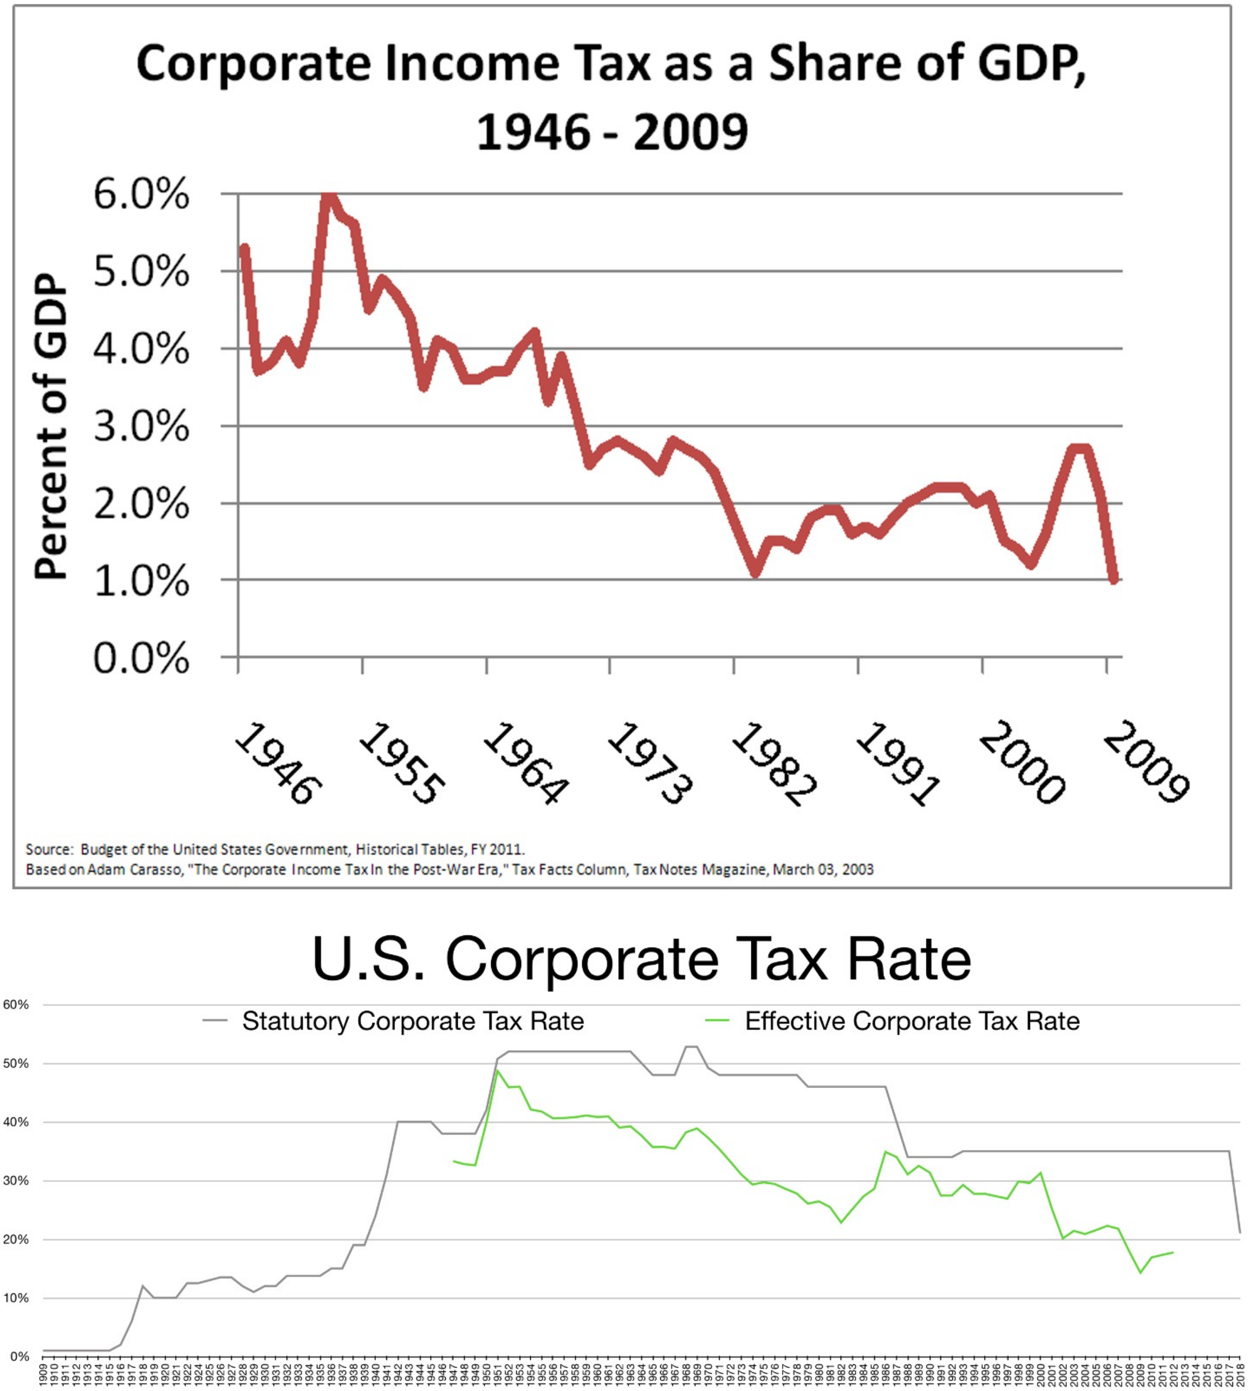
John Pierce, a research manager under Mervin Kelly at Bell Laboratories during its heyday, gave a very similar description of various external and internal forces that led Bell Laboratories to become less interested in innovative R&D after Kelly retired [Pierce 1975]:

> Kelly's concept of "organized creative technology," embracing research, fundamental (or exploratory) development, systems engineering, and final development for manufacture is persuasive. His concept of the place of basic research in industry is inspiring and appealing. What, however, are we to make of these in practice?
>
> There seems to be no avoiding Kelly's conclusion that industrial progress is based on the results of basic research. We can note that basic research is sometimes inspired by technological invention. Thermodynamics was inspired by the steam engine. But, whatever its inspiration, basic research lies behind the whole of modern technology. Kelly felt strongly that much basic research should be carried out in industrial laboratories.
>
> During Kelly's career at Bell Laboratories, he experienced (despite the years of the Depression) the relatively stable support derived from the provision of a service as opposed to the manufacture of products for the market place. The exception to this was defense work, but this was done during periods of close cooperation between government and industry in the national crises of World War II and the Korean War. These were circumstances far more favorable to research, or at least to the dedicated effort of first-rate men, than is work in a manufacturing industry where markets as well as revenues fluctuate.
>
> Further, in Kelly's time the effect on science of some government actions and attitudes was less clear than it is today. The consequences to science of antitrust actions that sever service from manufacture (in aircraft and airlines, for example), that render successful companies insecure in their operations and in cooperative relations with universities, and that prevent cooperative research toward common needs, were not yet clear. Further, in Kelly's time the attitude of government toward both science and industry was on the

> whole friendly and cooperative. Today, the attitude of government has, in many areas, become at once hostile, highly demanding, and minutely dictatorial through statutory and bureaucratic means.
>
> Thus, Kelly may have overestimated the amount and quality of research that could in the future be expected from industry, and perhaps from the nation.
>
> Some of Kelly's ideas concerning the organizational form most suitable for "organized creative technology" have hazards as well as power. The autonomy of research, the prerogatives of systems engineering, and the separation of the management of non-technological functions from the technological management depend for their success on inspired leadership.
>
> When leadership is uninspired or inadequate, it is easy for research to drift away from the overall purpose of an organization. It is easy for the rest of the organization to disregard research. It is easy for systems engineers to become stale and to lose their feel for the actual state of research on one hand and the current realities of development, manufacture, and operation on the other. It is easy for a large staff organization concerned with buildings, facilities, shops, libraries, and even computer services to put organizational order and budgetary neatness ahead of the real needs and problems of scientists and engineers.
>
> Above all, a technological organization must have the leadership to see and pursue real opportunities and real needs.

Thus beginning around 1970, U.S. companies became less and less supportive of innovative research and development, and that pattern continued for several decades. By the time another serious foreign competitor arose in China around 2000 or so, it became apparent that China could rapidly copy any U.S. innovation, mass-produce it, and sell it for less in U.S. and global markets. Therefore not only domestic but also foreign competition became a strong disincentive to invest in research and development of major new innovations.

High U.S. corporate tax rates during the 1940s–1960s were a strong incentive for executives to reinvest most of a company's income in research and development, infrastructure, and employees instead of trying to remove it from the company as cash profits and lose much of it.



Source: Budget of the United States Government, Historical Tables, FY 2011.
Based on Adam Carasso, "The Corporate Income Tax In the Post-War Era," Tax Facts Column, Tax Notes Magazine, March 03, 2003

Figure 11.75: High U.S. corporate tax rates during the 1940s–1960s were a strong incentive for executives to reinvest most of a company's income in research and development, infrastructure, and employees instead of trying to remove it from the company as cash profits and lose much of it.

11.2.11 Other Factors

Family backgrounds of creators

Just as a disproportionate percentage of innovators in the German-speaking world was Jewish, a disproportionate percentage in the U.S. system has also been Jewish. Currently approximately 2% of the U.S. population is Jewish or of Jewish background. Yet from 1901 through 2013, 25% of all U.S. Nobel Prize winners in science were Jewish and born in the Unites States. Including both those born in the United States and also those who immigrated to the United States from other countries of origin, 38% of all U.S. Nobel Prize winners in science were Jewish [Gerstl 2014, p. 87]. Those statistics may indicate that certain family backgrounds place more emphasis on intellectual education and careers, or even more specifically on science-related education and careers.

However, this factor is not sufficient for producing revolutionary scientific innovations. There are currently approximately six million Jewish people in the United States, as well as millions of people from all sorts of other backgrounds, yet the rate of revolutionary innovations per year (certainly the rate of revolutionary innovations per year per person) seems far lower than in earlier times. What appears to be lacking are the systemic approaches (such as those listed in previous sections) that fostered, supported, and rewarded revolutionary innovators and innovations in the German-speaking world and in the early U.S. system, but that have subsequently been largely abandoned.

Other possible factors

In addition to the factors already considered in this chapter, it is possible that other factors helped or hindered scientific innovation in the United States. In the future, scholars who examine this topic further should evaluate factors such as those listed on p. 2030, and determine how much if any effect each factor has had on innovation.

11.3 Failure to Sustain Approaches Transferred from the German-Speaking World

The U.S. research system was highly productive during its early decades in the 1940s–1960s, when it largely focused on perfecting creations it had imported from the earlier German-speaking world (Section 11.1), using thousands of creators (Section 11.1) and some systemic approaches (Section 11.2) that it had also imported from the German-speaking world. Unfortunately, productivity apparently declined after that period, as the original creations reached complete technological maturity, the original German-speaking creators retired or died, and the system drifted further from the approaches that had originally facilitated the successes of those creators and creations. In particular, research funding stagnated or declined (Figs. 11.62–11.64), far-sighted enlightened despots were replaced by consensus-based bureaucracies, and research shifted from longer-term development of revolutionary innovations to extremely low-risk production of immediately marketable commercial products or immediately publishable academic papers. This section quotes some first-hand observations of the apparent decline of the modern research system, then examines potential explanations for that decline.

11.3.1 Observations of Decline

The following are personal accounts from several discerning experts who observed these changes as they happened in all three sectors of the U.S. research system:

A. The university-based academic research system (p. 2245).

B. The corporate research system based in private company laboratories (p. 2254).

C. The government research system based in government-run and/or government-funded laboratories (p. 2256).

A. Observations of decline in the academic research system

Philip Anderson (1923–2020, 1977 Nobel Prize in Physics) was part of the U.S. research system from the 1940s onward and described its decline [Laurie Brown et al. 1995, pp. 2027–2029]:

> The gigantic growth... took place to a large extent because of a perception both in industry and in government that the products created were economically useful. The result was funding on a scale which absorbed essentially all new recruits. Through the first three postwar decades this was unquestionably the case; we hardly need to repeat the litany of practically useful materials and devices which came out during these years.
>
> [...] The result was an increasing overcrowding of research as a profession. One may question—and leaders of various kinds did—how much research is too much, or even whether there *could* be too much research, research being viewed as an absolute good. But conditions within the profession, viewed objectively, made it quite clear that aside from the inevitable funding crunch there were dysfunctions in the system.

> There was a very sharp change in the nature of a research career. The 'promising' young scientist's publication rate grew by factors of five to ten; the number of applications a young researcher might make for postdoctoral work or an entry-level position from two or three to 50. Senior scientists were overwhelmed with receiving and sending reams of letters of recommendation, which thereupon became meaningless. The numbers of meetings in a given specialized subject, and the number of subjects with a formal meeting list, both grew by factors of ten or more. In many subjects one could 'meet' nearly 52 weeks in the year, somewhere in the world, and leaders in the field were invited to all. Meetings almost inevitably led to publications. Most publications became tactical in this game of jockeying one's way to the top; publications in certain prestige journals were seen as essential entry tickets or score counters rather than as serious means of communication. Great numbers of these publications were about simulations of dubious realism or relevance. Essentially, in the early part of the postwar period the career was science-driven, motivated mostly by absorption with the great enterprise of discovery, and by genuine curiosity as to how nature operates. By the last decade of the century far too many, especially of the young people, were seeing science as a competitive interpersonal game, in which the winner was not the one who was objectively right as to the nature of scientific reality but the one who was successful at getting grants, publishing in PRL [*Physical Review Letters*], and being noticed in the news pages of *Nature*, *Science*, or *Physics Today.*
>
> In many subjects the great volume of publications, the fragmentation into self-referential so-called schools who met separately, and a general deterioration in quality which came primarily from excessive specialization and from careerist sociology, meant that quite literally more was worse.

Note that Anderson described all of these problems in 1995, and they have only become even more pronounced in the decades since then.

As early as 1972, Albert Szent-Györgyi (Hungarian, 1893–1986), the winner of the 1937 Nobel Prize in Physiology or Medicine, noticed similar problems in the American research system. In a letter to the journal *Science*, he complained about how the system had come to discriminate against funding revolutionary innovators who pioneered entirely new research directions (whom he labelled "Dionysians") in favor of only funding scientists who made evolutionary, incremental progress in already known directions ("Apollonians") [Szent-Györgyi 1972]:

> In science the Apollonian tends to develop established lines to perfection, while the Dionysian rather relies on intuition and is more likely to open new, unexpected alleys for research. [...]
>
> The future of mankind depends on the progress of science, and the progress of science depends on the support it can find. Support mostly takes the form of grants, and the present methods of distributing grants unduly favor the Apollonian. Applying for a grant begins with writing a project. The Apollonian clearly sees the future lines of his research and has no difficulty writing a clear project. Not so the Dionysian, who knows only the direction in which he wants to go out into the unknown; he has no idea what he is going to find there and how he is going to find it. [...]

> A discovery must be, by definition, at variance with existing knowledge. During my lifetime, I made two. Both were rejected offhand by the popes of the field. Had I predicted these discoveries in my applications, and had these authorities been my judges, it is evident what their decisions would have been. [...]
>
> The problem is a most important one, especially now, as science grapples with one of nature's mysteries, cancer, which may demand entirely new approaches.

Sydney Brenner (1927–2019), who won the Nobel Prize in Physiology or Medicine in 2002 for his work on molecular biology, described similar problems with the modern academic research system [Dzeng 2014]:

> In America you've got to have credits from a large number of courses before you can do a PhD. That's very good for training a very good average scientific work professional. But that training doesn't allow people the kind of room to expand their own creativity. But expanding your own creativity doesn't suit everybody. For the exceptional students, the ones who can and probably will make a mark, they will still need institutions free from regulation. [...]
>
> I strongly believe that the only way to encourage innovation is to give it to the young. The young have a great advantage in that they are ignorant. Because I think ignorance in science is very important. If you're like me and you know too much you can't try new things. I always work in fields of which I'm totally ignorant. [...]
>
> Today the Americans have developed a new culture in science based on the slavery of graduate students. Now graduate students of American institutions are afraid. He just performs. He's got to perform. The postdoc is an indentured labourer. We now have labs that don't work in the same way as the early labs where people were independent, where they could have their own ideas and could pursue them.
>
> The most important thing today is for young people to take responsibility, to actually know how to formulate an idea and how to work on it. Not to buy into the so-called apprenticeship. I think you can only foster that by having sort of deviant studies. That is, you go on and do something really different. Then I think you will be able to foster it.
>
> But today there is no way to do this without money. That's the difficulty. In order to do science you have to have it supported. The supporters now, the bureaucrats of science, do not wish to take any risks. So in order to get it supported, they want to know from the start that it will work. This means you have to have preliminary information, which means that you are bound to follow the straight and narrow.
>
> There's no exploration any more except in a very few places. You know like someone going off to study Neanderthal bones. Can you see this happening anywhere else? No, you see, because he would need to do something that's important to advance the aims of the people who fund science.
>
> I think I've often divided people into two classes: Catholics and Methodists. Catholics are people who sit on committees and devise huge schemes in order to try to change

things, but nothing's happened. Nothing happens because the committee is a regression to the mean, and the mean is mediocre. Now what you've got to do is good works in your own parish. That's a Methodist. [...]

I am fortunate enough to be able to do this because in Singapore I actually have started two labs and am about to start a third, which are only for young people. These are young Singaporeans who have all been sent abroad to get their PhDs at places like Cambridge, Stanford, and Berkeley. They return back and rather than work five years as a post-doc for some other person, I've got a lab where they can work for themselves. They're not working for me and I've told them that. [...]

They can have some money, and of course they've got to accept the responsibility of execution. I help them in the sense that I oblige them and help them find things, and I can also guide them and so on. We discuss things a lot because I've never believed in these group meetings, which seems to be the bane of American life; the head of the lab trying to find out what's going on in his lab. Instead, I work with people one on one, like the Cambridge tutorial. Now we just have seminars and group meetings and so on.

So I think you've got to try to do something like that for the young people and if you can then I think you will create. That's the way to change the future. Because if these people are successful then they will be running science in twenty years' time. [...]

Even God wouldn't get a grant today because somebody on the committee would say, oh those were very interesting experiments (creating the universe), but they've never been repeated. And then someone else would say, yes and he did it a long time ago, what's he done recently? And a third would say, to top it all, he published it all in an un-refereed journal (The Bible).

So you know we now have these performance criteria, which I think are just ridiculous in many ways. But of course this money has to be apportioned, and our administrators love having numbers like impact factors or scores. Singapore is full of them too. Everybody has what are called key performance indicators. But everybody has them. You have to justify them.

I think one of the big things we had in the old LMB [Laboratory of Molecular Biology], which I don't think is the case now, was that we never let the committee assess individuals. We never let them; the individuals were our responsibility. We asked them to review the work of the group as a whole. Because if they went down to individuals, they would say, this man is unproductive. He hasn't published anything for the last five years. So you've got to have institutions that can not only allow this, but also protect the people that are engaged on very long term, and to the funders, extremely risky work.

I have sometimes given a lecture in America called "The Casino Fund." In the Casino Fund, every organisation that gives money to science gives 1% of that to the Casino Fund and writes it off. So now who runs the Casino Fund? You give it to me. You give it to people like me, to successful gamblers. People who have done all this who can have different ideas about projects and people, and you let us allocate it.

> You should hear the uproar. No sooner did I sit down then all the business people stand up and say, how can we ensure payback on our investment? My answer was, okay make it 0.1%. But nobody wants to accept the risk. Of course we would love it if we were to put it to work. We'd love it for nothing. They won't even allow 1%. And of course all the academics say we've got to have peer review. But I don't believe in peer review because I think it's very distorted and as I've said, it's simply a regression to the mean.
>
> I think peer review is hindering science. In fact, I think it has become a completely corrupt system. It's corrupt in many ways, in that scientists and academics have handed over to the editors of these journals the ability to make judgment on science and scientists. There are universities in America, and I've heard from many committees, that we won't consider people's publications in low impact factor journals.
>
> Now I mean, people are trying to do something, but I think it's not publish or perish, it's publish in the okay places [or perish]. And this has assembled a most ridiculous group of people. I wrote a column for many years in the nineties, in a journal called *Current Biology*. In one article, "Hard Cases," I campaigned against this [culture] because I think it is not only bad, it's corrupt. In other words it puts the judgment in the hands of people who really have no reason to exercise judgment at all. And that's all been done in the aid of commerce, because they are now giant organisations making money out of it. [...]
>
> I think that this has now just become ridiculous and it's one of the contaminating things that young people in particular have to actually now contend with. I know of many places in which they say they need this paper in *Nature*, or I need my paper in *Science* because I've got to get a post-doc. But there is no judgment of its contribution as it is.

In an obituary for Frederick Sanger (1918–2013), the only person to ever win two Nobel Prizes in Chemistry (1958 and 1980), Sydney Brenner continued his analysis of how the research system has changed [Brenner 2014]:

> A Fred Sanger would not survive today's world of science. With continuous reporting and appraisals, some committee would note that he published little of import between insulin in 1952 and his first paper on RNA sequencing in 1967 with another long gap until DNA sequencing in 1977. He would be labelled as unproductive, and his modest personal support would be denied. We no longer have a culture that allows individuals to embark on long-term—and what would be considered today extremely risky—projects.

As another example of the change in academia over the last several decades, the British newspaper *The Guardian* wrote about Peter Higgs (1929–), who won a Nobel Prize in Physics in 2013 for having predicted the existence and properties of a fundamental particle, the "Higgs boson," 50 years before it was finally discovered [Aitkenhead 2013]:

> Peter Higgs, the British physicist who gave his name to the Higgs boson, believes no university would employ him in today's academic system because he would not be considered "productive" enough. [...]

> He doubts a similar breakthrough could be achieved in today's academic culture, because of the expectations on academics to collaborate and keep churning out papers. He said: "It's difficult to imagine how I would ever have enough peace and quiet in the present sort of climate to do what I did in 1964." [...]
>
> By the time he retired in 1996, he was uncomfortable with the new academic culture. "After I retired it was quite a long time before I went back to my department. I thought I was well out of it. It wasn't my way of doing things any more. Today I wouldn't get an academic job. It's as simple as that. I don't think I would be regarded as productive enough."

Even though the primary product of the academic research system is published papers, with their quantity considered far more important than their quality, even the content of those papers ends up largely unread, unknown, and unused. In part, that is because of (1) the completely overwhelming flood of papers and journals; (2) the fact that most academic researchers are too busy frantically writing their own papers to spend much time reading and applying other researchers' papers; and (3) the unnecessarily microspecialized vocabulary that academics keep creating, resulting in a "tower of Babel" effect that makes academics in even slightly different fields unintelligible to each other, let alone to their sponsors or the general public. [For the history of these trends, see for example: Buranyi 2017; Francis 2020.]

Another reason that published papers tend to have so little effect is that the large majority of scientific papers are inaccessible to most of the population due to exorbitant online journal paywalls or the cost or obscurity of the printed volumes in which they appear. Sarah Kendzior, who has a Ph.D. in anthropology, used the JSTOR (Journal Storage) electronic journal database as an example to illustrate this general problem [Kendzior 2015, pp. 124–129]:

> Universities that want to use JSTOR are charged as much as $50,000 in annual subscription fees.
>
> Individuals who want to use JSTOR must shell out an average of $19 per article. The academics who write the articles are not paid for their work, nor are the academics who review it. The only people who profit are the 211 employees of JSTOR. [...]
>
> Today, publishing in an academic journal all but ensures that your writing will go unread. [...] If I wanted to download my [own] articles, I would have to pay $183. That is the total cost of the six academic articles I published between 2006 and 2012[...]
>
> New professors are awarded tenure based on their publication output, but not on the impact of their research on the world—perhaps because, due to paywalls, it is usually minimal. [...]
>
> The academic publishing industry seems poised to collapse before it changes. But some scholars are writing about the current crisis. Last month, an article called "Public Intellectuals, Online Media and Public Spheres: Current Realignments" was published in the *International Journal of Politics, Culture and Society.*
>
> I would tell you what it says, but I do not know. It is behind a paywall.

In an article in *The New Yorker*, Ronan Farrow presented examples of how some modern universities appear to pursue money above all else [Farrow 2019]:

> New documents show that the M.I.T. Media Lab was aware of Epstein's status as a convicted sex offender, and that Epstein directed contributions to the lab far exceeding the amounts M.I.T. has publicly admitted.
>
> The M.I.T. Media Lab, which has been embroiled in a scandal over accepting donations from the financier and convicted sex offender Jeffrey Epstein, had a deeper fund-raising relationship with Epstein than it has previously acknowledged, and it attempted to conceal the extent of its contacts with him. Dozens of pages of e-mails and other documents obtained by *The New Yorker* reveal that, although Epstein was listed as "disqualified" in M.I.T.'s official donor database, the Media Lab continued to accept gifts from him, consulted him about the use of the funds, and, by marking his contributions as anonymous, avoided disclosing their full extent, both publicly and within the university. Perhaps most notably, Epstein appeared to serve as an intermediary between the lab and other wealthy donors, soliciting millions of dollars in donations from individuals and organizations, including the technologist and philanthropist Bill Gates and the investor Leon Black. According to the records obtained by *The New Yorker* and accounts from current and former faculty and staff of the media lab, Epstein was credited with securing at least $7.5 million in donations for the lab, including two million dollars from Gates and $5.5 million from Black, gifts the e-mails describe as "directed" by Epstein or made at his behest. The effort to conceal the lab's contact with Epstein was so widely known that some staff in the office of the lab's director, Joi Ito, referred to Epstein as Voldemort or "he who must not be named." [...]
>
> Questions about when to accept money from wealthy figures accused of misconduct have always been fraught. Before his conviction, Epstein donated to numerous philanthropic, academic, and political institutions, which responded in a variety of ways to the claims of abuse. When news of the allegations first broke, in 2006, a Harvard spokesperson said that the university, which had received a $6.5-million donation from him three years earlier, would not be returning the money. Following Epstein's second arrest, in 2019, the university reiterated its stance.

Further articles revealed the corrosive effect on research when universities value the immediate pursuit of huge amounts of money above everything else. For example, *Business Insider* reported on one project in "MIT's Media Lab Has an Ambitious Project That Purports to Revolutionize Agriculture. Insiders Say It's Mostly Smoke and Mirrors" [Brodwin 2019]:

> The "personal food computer," a device that MIT Media Lab senior researcher Caleb Harper presented as helping thousands of people across the globe grow custom, local food, simply doesn't work, according to two employees and multiple internal documents that Business Insider viewed. One person asked not to be identified for fear of retaliation.
>
> Harper is the director of MIT's Open Agriculture Initiative and leads a group of seven people who work on transforming the food system by studying better methods of growing crops.

> The food computers are plastic boxes outfitted with advanced sensors and LED lights and were designed to make it possible for anyone, anywhere to grow food, even without soil, Harper has said. Instead of soil, the boxes use hydroponics, or a system of farming that involves dissolving nutrients in water and feeding them to the plant that way. [...]
>
> Harper forwarded an email requesting comment on this story to an MIT spokesperson. The spokesperson didn't provide a comment.
>
> The aim was to make it look like the devices lived up to Harper's claims, the employees said. Those claims, which included assertions that the devices could grow foods like broccoli four times faster than traditional methods, landed Harper and his team articles in outlets ranging from the Wall Street Journal to Wired and National Geographic. [...]
>
> Paula Cerqueira, a researcher and dietitian who worked as a project manager at the Open Agriculture Initiative for two years, told Business Insider that the personal food computers are "glorified grow boxes."
>
> Cerqueira was part of a team that, on several occasions, delivered the personal food computers to schools. She also helped demonstrate the boxes to big-name MIT Media Lab investors.
>
> During the organization's "Members Weeks"—once-a-semester events that drew donors including Google, Salesforce, Citigroup, and 21st Century Fox—Cerqueira and her coworkers would show investors how the technology worked.
>
> On one occasion, Cerqueira said, her coworkers were told to fetch basil grown from a nearby location and place it into the personal food computers to make it look like it had been grown inside the boxes.
>
> "They wanted the best looking plants in there," Cerqueira told Business Insider. "They were always looking for funding."
>
> In another instance, Harper told Cerqueira to buy edible lavender plants from a nearby flower's market and place them in the boxes for a photoshoot, she said. Before any photos were taken, she carefully dusted off the tell-tale soil on the plants' roots.
>
> The central problem with the personal food computer was that it simply didn't work, Cerqueira and another person with knowledge of the matter told Business Insider.

The technology investor Peter Thiel summed up some of the problems with the modern academic research system in a 27 April 2023 speech [Thiel 2023]:

> Start with the university. It's easy to focus on all the insanity in the humanities. But if you remember what universities themselves believe—that all their serious work, their cutting- edge research, is done in the sciences—the focus on the humanities begins to resemble an attention redirect, stifling the hard questions about what is actually going on in the sciences. Are they progressing as advertised? Are we still living in an accelerating world in which science is fundamentally healthy and critical, with diversity

> of thought? It shouldn't have required covid to be able to ask these questions, to notice that "science" has somehow gotten to be a very, very diseased thing. Most imagine a scientist to be an independent researcher who thinks for himself, and this figure may still appear in children's books, but in practice the occupation mostly entails the enforcement of a fixed set of dogmas.
>
> A few years after *The Diversity Myth* came out, a Stanford physics professor, Bob Laughlin, got a Nobel Prize. And he began to suffer from the supreme delusion that, now that he had a Nobel Prize in physics, he also had academic freedom and could investigate anything he wanted. Now, there are a lot of controversial topics in science. You could have a heterodox view on stem-cell research, or you could be a skeptic of climate change or Darwinism. But Laughlin hit on a topic that was far more taboo than any of the above. He had the idea that most of the scientists were doing no work at all. They were actually stealing money from the government, just creating all these fraudulent grant applications. Laughlin had done a lot of work studying the physics of super-high temperatures (superconductivity and the like), and he once told me that, of the roughly fifty thousand papers written on the subject, maybe twenty-five of them were any good at all.
>
> Laughlin's team started with the biology department at Stanford, launching a sort of inquiry into what, exactly, it was doing. They didn't actually publish the results—they just had a public hearing and generally denounced all the professors as having stolen money from the government. The generous conclusion would be that the department wasn't fully fraudulent: just an incredibly incrementalist exercise in groupthink that wasn't really moving the dial forward. This was a line of thinking that was completely, completely taboo. I don't need to tell you how the story ends.
>
> This question of scientific and technological stagnation is in some sense the Achilles heel of the universities. It's hard to uncover. Right now the humanities are transparently ridiculous. You might think of the humanities as the Department of Motor Vehicles. And the physics department is sort of like the self-proclaimed rocket scientists at the National Security Agency. The crypsis makes their activities look more intelligent and more advanced. But my belief is that the DMV is probably better run than the NSA. The fact that you don't have a clue what's going on at the NSA gives you a hint as to which of the two is worse. Something like this is going on with the sciences more broadly.
>
> There are two basic debate techniques you can have when you're arguing with someone. You can go after the enemy at the weakest point, which in the college context is the humanities: it's ridiculous, and you're most likely to come away with a sort of tactical victory. But the other strategy is to go after the enemy's strongest point: to say there's no real science going on, that string theorists aren't making the fundamental breakthroughs that we're told, and that physicists have otherwise been twiddling their thumbs for fifty years. And if you can win that point, it's game, set, and match.

For related information on some of the corrosive factors affecting the academic research system, see pp. 49–51, 2262–2263, and the references cited therein [see also Buranyi 2017; Francis 2020; Preston 2021; Sarkowski 2001].

B. Observations of decline in the corporate research system

This book has already quoted Simon Ramo, cofounder of TRW, on how U.S. companies began to view R&D as more of a burden than an opportunity beginning in the 1970s (p. 52). On a similar note, Richard Rosenbloom (1933–2011, a professor at the Harvard Business School) and William Spencer (1931–, president of the SEMATECH semiconductor manufacturers' consortium) commented on the decline in industrial research in a 1993 conference paper [later published in Rosenbloom and Spencer 1996, pp. 1–2, 4–5]:

> Familiar exemplars of organizations devoted to industrial research include DuPont's Experimental Station in Wilmington, IBM's Watson Research Center in Yorktown Heights, AT&T's Bell Laboratories at Murray Hill, and the Xerox Palo Alto Research Center.
>
> The decades following World War II were a golden era for research organizations in American industry. Corporate leaders, persuaded by the dazzling achievements of wartime and such undisputed research successes as nylon and the transistor, funded rapid expansion of research staffs and facilities. DuPont, for example, increased its R&D staff by 150 percent in the first decade after the war and the greatest growth occurred at the Experimental Station, the center of its fundamental research in chemistry. Radio Corporation of America (RCA), a pioneer in electronics, formed the RCA Laboratories Division, with an expansive budget and a campus-like setting in Princeton, New Jersey. Implicit in the rationale for these investments was a simple model of innovation: Scientific research in industry would generate a stream of inventions and discoveries that engineering would then make practical and affordable so that commercial organizations could harvest new revenues and profits.
>
> The stream of industrial innovations that ensued from these investments fulfilled at least the first part of this ambitious corporate vision. Industrial laboratories proved to be wellsprings of important new technologies that then became staples of modern life, such as the integrated circuit, liquid crystals, and a multitude of new synthetic polymers, to name only a few. The interplay of university and corporate laboratories brought the development of lasers, techniques of recombinant DNA, and a host of computer technologies. [...]
>
> Unfortunately, technological fecundity and scientific distinction did not always carry through to the corporate bottom line. Although the new science and technology created in industry contributed substantially to economic growth and productivity, corporate sponsors of the research often failed to capture significant returns. At first, buoyant demand in the U.S. economy in the 1950s and 1960s and the strong international market positions of the leaders in industrial research made it easy for those firms to sustain substantial investments in research even without clear evidence of immediate payoffs. The more competitive business environment of the 1980s, however, led managers to make more careful assessments of the profits gleaned from research. [...]
>
> One after another, these firms are restructuring, redirecting, and resizing their research organizations as part of a corporatewide emphasis on the timely and profitable commercialization of inventions combined with the rapid and continuing improvement of technologies in use. A recent authoritative survey of the American situation by the Na-

> tional Science Board (NSB) has concluded that "In large corporations, effort is shifting away from central [R&D] laboratories toward division-level effort with greater emphasis on risk minimization to meet the needs of today's customers" (National Science Board 1992, iii).
>
> When the directors of Kodak decided to replace Kay Whitmore, the company's chief executive, they let reporters know that one of his most important failings was that he "spent too much on R&D without getting results." According to an article in the *Wall Street Journal*, investors applauded the move, urging Kodak to "become an 'aggressive follower' by capitalizing on rivals' inventions instead of mostly developing its own." Reporters did not record which rivals were expected to replace Kodak as the technological pioneers that the company would imitate. IBM also cut the annual budget of its research division from $650 million to $500 million and redirected its focus toward "Services, Applications, and Solutions" [SAS] and away from investments in basic physical sciences and technology. The company planned to increase the SAS budget from 5 percent to 20 percent of the division's total between 1992 and 1994 with correspondingly sharp reductions in funding for basic sciences.

In the decades since Rosenbloom and Spencer made those observations, corporate research has shifted even further away from innovative research, with top management and investors focused only on daily stock prices and very near-term, very low-risk (non-innovative) products.

More broadly, the changes in corporate culture are illustrated by public statements by the Business Roundtable, a group of U.S. CEOs [Archie Carroll et al. 2012; Pearlstein 2018]. The Business Roundtable's 1981 Statement on Corporate Responsibility reflected the traditional values that had been preached (if not always practiced) by U.S. businesses since the 1930s:

> Corporations have a responsibility, first of all, to make available to the public quality goods and services at fair prices, thereby earning a profit that attracts investment to continue and enhance the enterprise, provide jobs, and build the economy. [...] Responsibility to all these constituents in toto constitutes responsibility to society, making the corporation both an economically and socially viable entity. Business and society have a symbiotic relationship: The long-term viability of the corporation depends upon its responsibility to the society of which it is a part. And the well-being of society depends upon profitable and responsible business enterprises.

In stark contrast, the Business Roundtable's 1997 Statement on Corporate Responsibility revealed a focus on one thing, to the exclusion of all else:

> The principal objective of a business enterprise is to generate economic returns to its owners. If the CEO and the directors are not focused on shareholder value, it may be less likely the corporation will realize that value.

Thus companies such as those represented by the Business Roundtable not only chose to neglect research and other longer-term investments but explicitly eliminated any sense of responsibility to society or even to their own employees. Short-term profits for those individuals running the company or making money from the company became the only goal that mattered.

C. Observations of decline in the government research system

After the 1969 U.S. victory in the moon race, and the end of any serious further international space competition, U.S. government funding for space-related research and development began to decline. However, there were similar declines in other areas of government-funded research.

Beginning in fiscal year 1970, government funding for longer-term research was severely limited by a budget amendment introduced by Senate Majority Leader Mike Mansfield. He also introduced a second, further restrictive amendment in 1973. The U.S. Office of Technology Assessment briefly explained the first Mansfield Amendment [OTA 1991, p. 61]:

> The celebrated Mansfield amendment, passed as part of the fiscal year 1970 Military Authorization Act (Public Law 91-121), prohibited military funding of research that lacked a direct or apparent relationship to specific military function. Through subsequent modification the Mansfield amendment moved the Department of Defense toward the support of more short-term applied research in universities.

Soon after the first Mansfield Amendment in 1970, the chemist Herbert Laitinen published an accurate prediction of the long-term changes it would cause to the U.S. research system [Laitinen 1970]:

> Late in 1969, the Congress of the United States passed an authorization bill for expenditures of the Department of Defense for the fiscal year 1970. An amendment by Sen. Mansfield which passed with virtually no advance public notice has since caused apprehension, confusion, and secondary effects of a magnitude that still eludes estimation.
>
> The amendment, called section 203, states "None of the funds authorized by this Act may be used to carry out any research project or study unless such project or study has a direct and apparent relationship to a specific military function." [...]
>
> Now that the issue of "direct and apparent relationship to a specific military function" has been raised, a similar "Mansfield effect" appears to be emerging in mission-oriented civilian agencies, such as the National Institutes of Health and the Federal Water Pollution Control Agency, to require a closer and more obvious relationship between research and mission. [...] If it were simply a matter of transfer of funds to the one research agency that is not mission-oriented, the National Science Foundation, no serious harm would be done. Unfortunately, the NSF is not receiving additional support. On the contrary, it has been directed, through the Daddario bill, to expand its function to support applied as well as basic research [with its existing budget]. Thus, an already serious squeeze on pure research seems destined to intensify.
>
> Now to complete the circle, the emergence on the job market of a pool of postdoctorates that can no longer be supported on research grants, plus the new group of graduating Ph.D.'s to compete for a dwindling number of research positions in industry, government, and academic departments is being cited as evidence that we have an abundance of Ph.D.'s and that decreased graduate support is therefore justified. Clearly this is short-sighted policy. What is needed is a strong and continuing commitment to basic research in support of all mission-oriented technology, both in relation to research training at pre- and postdoctoral levels and in relation to research output. Anything less will

> waste the talents of a substantial group of skilled research workers and will compromise our technological future.

An old version of the history of DARPA (the Defense Advanced Research Projects Agency) archived on the internet explained the second Mansfield Amendment of 1973 [https://www.bibliotecapleyades.net/sociopolitica/sociopol_DARPA01.htm]:

> The Mansfield Amendment of 1973 expressly limited appropriations for defense research (through ARPA/DARPA) to projects with direct military application.
>
> Some contend that the amendment devastated American science, since ARPA/DARPA was a major funding source for basic science projects of the time; the National Science Foundation never made up the difference as expected. But the resulting "brain drain" is also credited with boosting the development of the fledgling personal computer industry.

While the decline in U.S. government-funded research began around 1970, it became even worse with the end of the Cold War in 1991. Lynn Gref (1941–2013), who spent his career conducting and managing research at Department of Defense (DOD) and NASA laboratories, described the decline of applied research or "Phase Two" research at government laboratories [Gref 2010, pp. 116–117]:

> It is in Phase Two research (device phase) that a decline in research activity of at least a decade duration can be detected. Now let us consider the indicators of a decline in Phase Two research. [...I]ndustry has become the dominant source of funds for R&D. Industry is even more dominant for R&D outside of the medical science arena. This is in itself not necessarily bad. However, it will become evident that industry has lost much of its ability or willingness to perform the Phase Two research that leads to the revolutionary devices of the future.
>
> Second, R&D performed at the Government's laboratories has declined more than 50% since 1970 based on funding received[...] Most of their work falls into Phase Two. After the end of the Cold War, funding for new weapons systems declined dramatically. (The Iraq War has brought an influx of orders for existing weapons systems and benefited much of the remaining defense industry, but it has had the devastating effect of further restricting R&D funding to efforts with an immediate application to the war.) The defense industry went through a major restructuring and consolidation between the end of the Cold War and the beginning of the Iraq War. During this period, industry went after all available funding from the DOD. The large companies turned to sources they previously shunned including Phase Two research. The companies employed massive lobbying efforts to achieve these objectives. Consequently, a goal of the DOD's laboratories became spending approximately 70% of their funding with industry. (The DOD originally established the laboratories to perform research needed by the services. Buying research from industry is a very recent occurrence.) This had two negative effects. First, it further reduced the funds retained by the laboratories to use for their in-house activities including research. The impact was that of a funding cut. Second, the technologists at the laboratories had to use their time to perform contracting functions—writing requests for proposals, evaluating proposals and monitoring the work of contractors—instead of performing their own research. The reduction of internal funding and the change in assignments has dramatically reduced research performed at the DOD laboratories. In addition, studies initiated by Congress have pointed to a

> perceived excess capacity in DOD laboratories and suggested restructuring the laboratories so that they would be Government owned and contractor operated. In this latter case, industry would perform all of DOD's research other than that done by universities. Recalling [...] the rich heritage of innovation of the Naval Research Laboratories and the other DOD service laboratories, the decline in technology development by DOD's laboratories is a tragedy for Phase Two of the development cycle.
>
> The "industrialization of Government research" has not been unique to the DOD. It has affected agencies such as NASA. NASA has terminated "block" funding of technology work at its center laboratories. It has replaced the technology development that its centers previously performed on an assigned basis with various competitions, most of which are open to all comers. With these competitions has come the pressure on NASA to award industry a greater proportion of the R&D dollars. The contraction and consolidation of the military industrial contractors that occurred after the end of the Cold War certainly had a part in this change at NASA as it did with the DOD laboratories. With the need to survive, NASA's research funds became fair game for these contractors. Unfortunately, when the researchers at the NASA centers fail to obtain funding for their efforts, then they must go elsewhere and their research ends. For example, JPL received from NASA approximately $100M on an assigned basis for Phase Two research in FY2000 and today it is less than $50M, mostly obtained on a competitive basis.
>
> Furthermore, competition for Phase Two funding does not foster risk taking and long-term efforts. No matter how one cuts it, the winners of funding are those who can demonstrate the best value for the Government. That is, winners are those that can identify measurable benefits of their research, demonstrate the risks of the proposed work are reasonable and manageable, prove the approach to the research is sound, and argue that success is likely. That just is not the real life situation for Phase Two research [...] where failure occurs more often than success.
>
> Competing for research funding is an environment in which research becomes incremental and unimaginative. In other words, the competitive environment turns the researchers into "surviving" financially. Improving the materials and processes used to build a device is much more likely to meet the requirements of a competition than some "wild new" idea that may take a decade or more to work out with few, if any, applications apparent[...] Similarly, proposing an enhancement to work that has already been funded and is in a proven interest area of the sponsor is more likely to be a successful bid than an "out of the box" or "off the wall" idea. Such a chilling environment for innovation is not conducive to funding research ideas that could really have an impact similar to those of NRL's radar developments of the past.

Summary of observations of decline

According to longtime first-hand observers such as those quoted above, the academic, corporate, and government research sectors of the U.S. innovation system were all very productive during the 1940s–1960s, all began to drift and steadily decline beginning around 1970 or so, experienced a further drop around the end of the Cold War ($\sim$1991), and have declined even more since 2000 due to priority shifts at the highest levels of government, industry, and academia. The end result is the problems discussed in Section 1.1.

11.3.2 Explanations for Decline

The contemporary observers quoted in the previous section ably described the decline in innovation that occurred from around 1970 onward, yet it is necessary to seek a better understanding of the fundamental reasons for that decline. A number of potential explanations have been offered:

A. Exhaustion of the supply of innovators and innovations that had been adopted from the earlier German-speaking world (p. 2259).

B. Abandonment of German-like systemic practices for promoting innovation (p. 2260).

C. The decline and end of Cold War competition that promoted innovation (p. 2260).

D. Darwinian selection of researchers for traits other than innovation (p. 2262).

E. Political divisions that undermine government support for innovation (p. 2264).

F. Loss of consumer demand for innovation (p. 2265).

G. A shift in the types of innovation that consumers demand (p. 2266).

In practice, all of these factors probably played a significant role in the decline, and indeed the various factors likely exacerbated each other.

A. Exhaustion of innovators and innovations adopted from the German-speaking world

As argued in Chapters 2–10 and Section 11.1, a huge number of innovators and innovations were produced by the German-speaking world prior to 1945. By around 1970, most of the thousands of German-speaking creators who had been recruited from that world had retired or died, and the enormous numbers of inventions and discoveries that had originated in that earlier world had already been copied, optimized, and utilized to their fullest potential in the United States and other countries.

B. Abandonment of German-like systemic practices for promoting innovation

As covered in Sections 11.2 and 11.3.1, especially during the 1940s–1960s, the United States (and presumably other countries) implemented many systemic practices that strongly promoted revolutionary scientific innovation, and that were highly similar to systemic practices from the earlier German-speaking world. Just as those practices had cultivated countless creators and creations in the German-speaking world, they also bred homegrown innovators and innovations in the United States. Unfortunately, around 1970, the United States began to abandon some of those systemic practices. That shift made it harder to cultivate as many brand new revolutionary innovators and innovations after that time, and it also made it harder for any innovators and innovations that had been developed in the earlier days of the system to continue to find sufficient financial and political support.

C. Decline and end of Cold War competition that promoted innovation

As argued in Section 11.2.9, just as the earlier German-speaking world was strongly driven throughout its existence by military and industrial competition with the United Kingdom, United States, and other countries, the U.S. system in the 1940s through 1960s was strongly driven first by World War II competition with Germany and then by Cold War competition with the Soviet Union. However, around 1970 (with the U.S. victory in the moon race and the beginning of the Strategic Arms Limitation Talks) that Cold War competition greatly relaxed, and in 1991 it collapsed entirely. Without a strong sense of urgent international competition, the U.S. innovation system fell victim to other priorities and forces.

In the afterword to his book *The Gift*, writing professor Lewis Kenyon described how the end of the Cold War impacted both scientists and artists, with funding decreasing and shifting from longer-term, more philanthropic objectives to very short-term, purely money-making aims [Hyde 2019]:

> Which brings me back to the fall of the Soviet Union, for it was the Cold War that energized much of the public funding devoted to art and science in the decades after World War II. [...]
>
> Of that context one could say, to put it positively, that the Soviet Union turned out to provide a useful counterforce to the harsher realities of capitalism. It goaded the West into provisioning those parts of social life not well served by market forces. To put it negatively, however, if Cold War rhetoric lay at the foundation, then the entire edifice was historically vulnerable. Thus when the Soviet Union fell in 1989 so did the bulk of public patronage in the West. In the U.S., for example, we almost immediately got the attacks on the National Endowment for the Arts and the loss of nearly all funding to individual artists. A similar if less publicized story played out in basic science. In a 1998 interview Leon Lederman, Nobel laureate in physics, said: "We always thought, naïvely, that here we are working in abstract, absolutely useless research and once the cold war ended, we wouldn't have to fight for resources. Instead, we found, we were the cold war. We'd been getting all this money for quark research because our leaders decided that science, even useless science, was a component of the cold war. As soon as it was over, they didn't need science."

> In short, around 1990 the third phase of this history began, an era of market triumphalism in which not only has public support of the arts and sciences begun to dry up but those who stilled their voices during the Cold War, those who have long believed in an unlimited market, have felt free to advance unselfconsciously.
>
> In instance after instance, public institutions have been encouraged to think of themselves as private businesses. The universities have set up "technology transfer offices" and tried to fund themselves by selling knowledge rather than simply disseminating it, as their old mission statements once asked them to do. Grammar schools have learned that they can sell exclusive rights to soft drink vendors intent on creating brand loyalty in the very young. Public radio and television are now cluttered with advertising. Even commercial television has become more so: in the U.S., the networks once limited their ads to nine minutes an hour; they gave that up in the last decade and ads now run eighteen minutes in prime time.
>
> Natural abundance has been similarly commercialized, everywhere subject to the grid of artificial scarcity. Ancient aquifers, by rights belonging to all who live above them, are now pumped and packaged. Drinking water, once an essence of life, has become a resource to be sold in little plastic bottles. Broadcast spectrum, one of nature's richest gifts, has been parceled out to industry and then sold back to the public.
>
> Our cultural abundance suffers the same fate. The ever-expanding reach of copyright has removed more and more art and ideas from the public domain. The Walt Disney Company happily built its film empire out of folk culture ("Snow White," "Pinocchio") but any folk who try to build on Disney can expect a "cease and desist" letter in the next mail. Patents are now used to create property rights in things once thought inalienable–seedlines, human genes, medicines long known to indigenous cultures. A company that makes jam recently got itself a patent on the crustless peanut butter-and-jelly sandwich.
>
> This period of market triumphalism has, in sum, seen a successful move to commercialize a long list of things once thought to have no price, and to enclose common holdings, both natural and cultural, that we used to assume no one was allowed to take private.

Broadening out the discussion beyond just scientific innovation, there appears to have been a sea change in the entire U.S. economy and society around the early 1970s. Economic analyses have shown that from the 1940s until around 1970, the United States experienced strong economic growth, and that growth was shared across all parts of the population. Those same economic analyses have demonstrated that from the 1970s onward, U.S. economic growth was often much weaker than in the preceding decades, and the rewards for what growth did occur were increasingly concentrated in the hands of the wealthiest individuals and companies [Carter Price and Edwards 2020; Saez and Zucman 2016].

It appears that as Cold War competition waned, the wealthiest individuals and their political allies no longer needed the broader population to help produce new innovations, share in their success and generated income, and mount a competition with the Soviet Union. Rather, they seem to have turned toward simply vacuuming up as much of the pre-existing innovations, resources, and wealth as possible, leaving the innovation system and the general populace to suffer a slow but steady decline from the 1970s onward.

D. Darwinian selection of researchers for traits other than innovation

As the United States began to abandon innovation-promoting practices like those from the earlier German-speaking world, from the 1970s onward the modern system came increasingly to value the sheer number of academic papers much more than their quality or significance. Since academic scientists were now rewarded with funding primarily based on their number of published papers rather than the scientific quality, originality, or importance of their work, labs that emphasized quantity over quality received more funding, trained more students, and graduated those students into the system to create their own labs that focused on quantity over quality. In a Darwinian fashion, within a few cycles of "reproduction," scientists who emphasized quantity over quality became vastly more numerous and much more powerful (as peer review committee members for research grant funding, hiring, and tenure decisions) than any remaining scientists who valued the quality, originality, and revolutionary importance of research.

Two scientists, Paul Smaldino and Richard McElreath, described the impact of Darwinian selection for traits other than revolutionary innovation, applied to generation after generation of professors and their students [Smaldino and McElreath 2016]:

> This paper argues that some of the most powerful incentives in contemporary science actively encourage, reward and propagate poor research methods and abuse of statistical procedures. We term this process the natural selection of bad science to indicate that it requires no conscious strategizing nor cheating on the part of researchers. Instead, it arises from the positive selection of methods and habits that lead to publication. How can natural selection operate on research methodology? There are no research 'genes'. But science is a cultural activity, and such activities change through evolutionary processes. Philosophers of science such as Campbell, Popper and Hull have discussed how scientific theories evolve by variation and selection retention. But scientific methods also develop in this way. Laboratory methods can propagate either directly, through the production of graduate students who go on to start their own labs, or indirectly, through prestige-biased adoption by researchers in other labs. Methods which are associated with greater success in academic careers will, other things being equal, tend to spread.
>
> The requirements for natural selection to produce design are easy to satisfy. Darwin outlined the logic of natural selection as requiring three conditions:
>
> (i) There must be variation.
>
> (ii) That variation must have consequences for survival or reproduction.
>
> (iii) Variation must be heritable.
>
> In this case, there are no biological traits being passed from scientific mentors to apprentices. However, research practices do vary. That variation has consequences—habits that lead to publication lead to obtaining highly competitive research positions. And variation in practice is partly heritable, in the sense that apprentices acquire research habits and statistical procedures from mentors and peers. Researchers also acquire research practice from successful role models in their fields, even if they do not personally know them. Therefore, when researchers are rewarded primarily for publishing, then habits which promote publication are naturally selected. Unfortunately, such habits can directly undermine scientific progress. [...]

> The rate at which new papers are added to the scientific literature has steadily increased in recent decades. This is partly due to more opportunities for collaboration, resulting in more multi-author papers. However, the increases in publication rate may also be driven by changing incentives. Recently, Brischoux & Angelier looked at the career statistics of junior researchers hired by the French CNRS in evolutionary biology between 2005 and 2013. They found persistent increases in the average number of publications at the time of hiring: newly hired biologists now have almost twice as many publications as they did 10 years ago (22 in 2013 versus 12.5 in 2005). These numbers reflect intense competition for academic research positions. The world's universities produce many more PhDs than there are permanent academic positions for them to fill, and while this problem has escalated in recent years, it has been present for at least two decades. Such competition is all the more challenging for researchers who graduate from any but the most prestigious universities, who face additional discrimination on the job market. Although there may be jobs available outside of academia— indeed, often better-paying jobs than university professorships—tenure-track faculty positions at major research universities come with considerable prestige, flexibility and creative freedom, and remain desirable. Among those who manage to get hired, there is continued competition for grants, promotions, prestige and placement of graduate students.
>
> Given this competition, there are incentives for scientists to stand out among their peers. Only the top graduate students can become tenure-track professors, and only the top assistant professors will receive tenure and high profile grants. [...]
>
> Incentives drive cultural evolution. In the scientific community, incentives for publication quantity can drive the evolution of poor methodological practices. We have provided some empirical evidence that this occurred, as well as a general model of the process. If we want to improve how our scientific culture functions, we must consider not only the individual behaviours we wish to change, but also the social forces that provide affordances and incentives for those behaviours. We are hardly the first to consider a need to alter the incentives for career success in science. However, we are the first to illustrate the evolutionary logic of how, in the absence of change, the existing incentives will necessarily lead to the degradation of scientific practices.
>
> An incentive structure that rewards publication quantity will, in the absence of countervailing forces, select for methods that produce the greatest number of publishable results. This, in turn, will lead to the natural selection of poor methods and increasingly high false discovery rates. Although we have focused on false discoveries, there are additional negative repercussions of this kind of incentive structure. Scrupulous research on difficult problems may require years of intense work before yielding coherent, publishable results. If shallower work generating more publications is favoured, then researchers interested in pursuing complex questions may find themselves without jobs, perhaps to the detriment of the scientific community more broadly. [...]
>
> Institutional change is difficult to accomplish, because it requires coordination on a large scale, which is often costly to early adopters. Yet such change is needed to ensure the integrity of science.

Other scholars have made very similar arguments about the perverse incentives warping academic research [Bhattacharya and Packalen 2020; Charlton 2009; Chu and Evans 2021; Ritchie 2020].

E. Political divisions that undermine government support for innovation

Severe political divisions in the United States arose by the late 1960s and have only worsened since then, undermining strong government understanding of, support for, and utilization of revolutionary innovation as had existed earlier. The science policy analysts Chris Mooney and Sheril Kirshenbaum described the impact on scientific innovation [Mooney and Kirshenbaum 2010, pp. 28–29]:

> Yet the heyday of science wouldn't last long. The trend of ever-rising federal investment in research reversed itself in the late 1960s; non-military science funding fell through much of the 1970s. The central involvement of the National Science Foundation in shaping high school educational curricula also gradually fell away—as did the prominence of the scientific elite in advising our leaders.
>
> All this occurred for a snarl of reasons that center on the collapse of political consensus in America over the same time period. The scientific community couldn't escape the conflicts of the day any more than any other major social group. The creation of new regulatory agencies, like the Environmental Protection Agency in 1970, repeatedly dragged scientific information into a contested decision-making process. And the growing antiwar and antinuclear movements flailed not only against the "military-industrial complex" but against those parts of the scientific establishment that worked with it or for it, especially on university campuses.
>
> Not only did the new mood of "questioning authority" include the questioning of science, but there was often good reason for skepticism. The environmental and consumer movements, spearheaded by the likes of Rachel Carson and Ralph Nader, brought home the realization that science wasn't always beneficial. Seemingly wonderful technologies—DDT, chlorofluorocarbons—could have nasty, unforeseen consequences. A narrative began to emerge about "corporate science": driven by greed, conducted without adequate safeguards, placing profits over people.
>
> Amid the backlash, the role of scientists in policy making also ebbed, as did the status of the presidential science advisor. Whereas the post had enjoyed a high level of recognition and influence under Eisenhower and Kennedy, the Vietnam War brought that cozy relationship to an end. In 1973, President Richard Nixon fired his science advisers outright over disagreements about the viability of the Supersonic Transport program and other matters.
>
> The emergence of the Religious Right onto the political stage in the 1970s—motivated in part by its adherents' resentment of the nation's intellectual and scientific elites—was also a major factor in curtailing the role of science in public policy. Soon battles between Christian conservatives and the science community over matters like the teaching of evolution and embryo-related research became an inescapable political reality. And so we entered the "culture wars": Secular, scientific, and pro-choice America clashed regularly with a "faith-based" (and very Republican) side of the country. A vast array of political issues could be cast in a pugilistic context that pitted "religion" against "reason." Science ceased to serve as a bulwark for common goals and purposes; instead, its findings came to divide us.

Other books have made similar arguments that increasing political divisions have fostered hostility toward scientists and the loss of innovation or even functionality within the scientific system [e.g., Gruber and Johnson 2019; Mooney 2006; Otto 2016]. By 2020, the consequences of these long-term trends in the United States were all too visible to the entire world.

F. Loss of consumer demand for innovation

Biologist Jan Vijg argued persuasively that the rate of revolutionary scientific innovation has greatly declined in recent decades, then offered his views on the causes of that decline. While the world at present may not be as nearly utopian as Vijg viewed it in 2011, his fundamental point seems sound: In contrast to circumstances that prompted revolutionary innovations in the past, currently there are not enough people with enough power who are sufficiently dissatisfied with the current state of technology to be strongly motivated to change it, and in fact many are strongly motivated to resist change [Vijg 2011, pp. 109–110]:

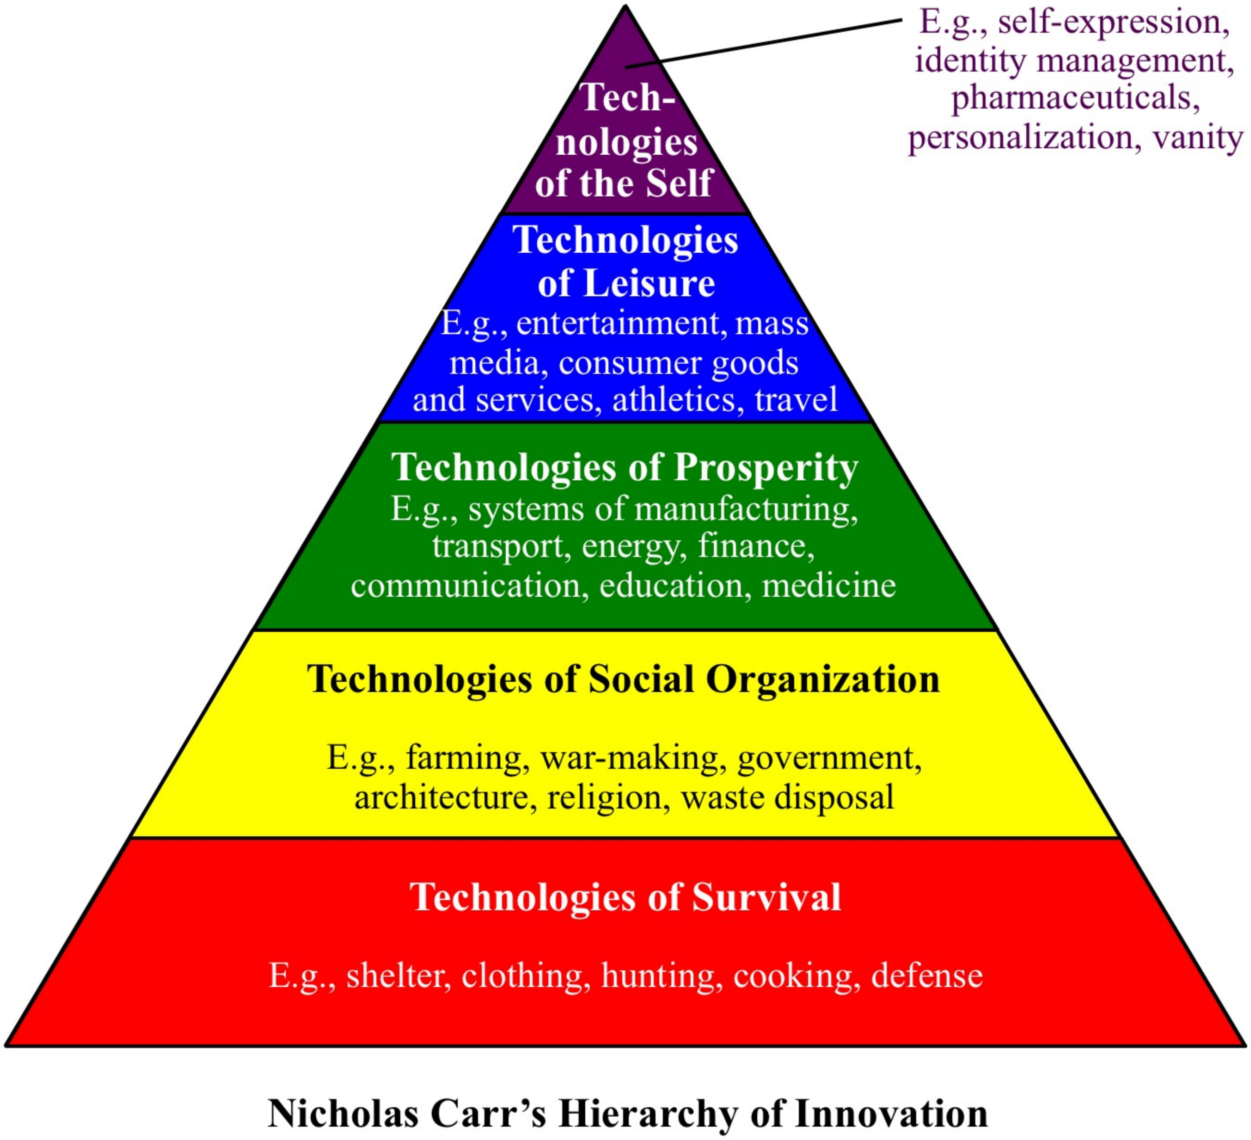
> The cold war is over and most current states profess support for democracy, the rule of law and a safety net for everyone. Almost all of us seem to have abandoned violence as a way to make progress. Representatives of the earth's states meet regularly and although we tend to think that nothing ever comes out of these meetings, the reality is that there are probably very few citizens who do not profit from the myriad of changes that slowly but surely transform us into a planet-wide commonwealth of states with almost unrealistically good credentials. Good governance, responsible industry leaders and better citizens slowly but irrepressibly take hold of society by creating a network of rules and regulations that make it all but impossible to run roughshod over others. People around the world are becoming healthier, wealthier, better educated, more peaceful, and increasingly connected, and they are living longer.
>
> Precisely because society is so successful, with technology maturing and all structures in place for optimally using it to the benefit of humankind, it has now become very difficult for new, breakthrough inventions to thrive. Investments are more likely in areas that have stabilized and proved their mettle, and regulatory constraints make it often very difficult for new inventions to get a fair chance at being implemented. This is especially true for medicine and biotechnology, two areas where scientific input should all but guarantee rapid progress. However, it also applies to the energy and transportation sectors where we witness a stalling of progress in strategic technologies. In spite of the hype in glossy magazines and the occasional newspaper article, to maintain the current fleet of passenger planes is simply too convenient and the days of Howard Hughes are definitely over. Surprisingly enough, this even applies to information technology where progress has helped us enormously to do the things we were already doing much quicker and in a much more convenient way than in the past. However, it does no longer break new ground and does not radically alter the way we live and work.
>
> In a sense, we have become a victim of our own success. The intricate net we have woven to protect each and every one of us from harm, to allow a maximum of input to everyone in decision making and to patiently listen to all arguments have turned us into the most successful society the world has ever seen. But paradoxically, this very success is now beginning to hold us back from making the further great strides to again transform human society, like the tremendous achievements of the 19^{th} and 20^{th} centuries did before.

G. Shift in the types of innovation that consumers demand

Both Nicholas Carr and Tyler Cowen proposed that the most financially lucrative demand for innovations has shifted from truly revolutionary technologies to mundane consumer products with annual cosmetic updates, "feel-good" products like Facebook and Prozac, and non-technological products for the very wealthy [Carr 2015; Cowen 2011].

Wall Street Journal writer and book author Nicholas Carr argued that the apparent slowdown in revolutionary innovations is largely driven by consumers who are more interested in "technologies of the self" than in more world-changing technologies [Carr 2012, 2015]. Carr's thesis has significant overlap with Jan Vijg's argument (modern society is sufficiently comfortable that innovation is no longer a priority). Carr explained his viewpoint with an essay [Carr 2015] and an accompanying diagram (redrawn in Fig. 11.76):

> Let me float an alternative explanation: There has been no decline in innovation; there has just been a shift in its focus. We're as creative as ever, but we've funneled our creativity into areas that produce smaller-scale, less far-reaching, less visible breakthroughs. And we've done that for entirely rational reasons. We're getting precisely the kind of innovation that we desire—and that we deserve.
>
> My idea—and it's a rough one—is that there's a hierarchy of innovation that runs in parallel with Abraham Maslow's famous hierarchy of needs. Maslow argued that human needs progress through five stages, with each new stage requiring the fulfillment of lower-level, or more basic, needs. So first we need to meet our most primitive Physiological needs, and that frees us to focus on our needs for Safety, and once our needs for Safety are met, we can attend to our needs for Belongingness, and then on to our needs for personal Esteem, and finally to our needs for Self-Actualization. If you look at Maslow's hierarchy as an inflexible structure, with clear boundaries between its levels, it falls apart. Our needs are messy, and the boundaries between them are porous. A caveman probably pursued self-esteem and self-actualization, to some degree, just as we today spend effort seeking to fulfill our physical needs. But if you look at the hierarchy as a map of human focus, or of emphasis, then it makes sense—and indeed seems to be born out by history. In short: The more comfortable you are, the more time you spend thinking about yourself.
>
> If progress is shaped by human needs, then general shifts in needs would also bring shifts in the nature of technological innovation. The tools we invent would move through the hierarchy of needs, from tools that help safeguard our bodies on up to tools that allow us to modify our internal states, from tools of survival to tools of the self. Here's my crack at what the hierarchy of innovation looks like [...]:
>
> The focus, or emphasis, of innovation moves up through five stages, propelled by shifts in the needs we seek to fulfill. In the beginning come Technologies of Survival (think fire), then Technologies of Social Organization (think cathedral), then Technologies of Prosperity (think steam engine), then technologies of leisure (think TV), and finally Technologies of the Self (think Facebook, or Prozac).



E.g., self-expression, identity management, pharmaceuticals, personalization, vanity
Technologies of the Self
Technologies of Leisure
E.g., entertainment, mass media, consumer goods and services, athletics, travel
Technologies of Prosperity
E.g., systems of manufacturing, transport, energy, finance, communication, education, medicine
Technologies of Social Organization
E.g., farming, war-making, government, architecture, religion, waste disposal
Technologies of Survival
E.g., shelter, clothing, hunting, cooking, defense
Nicholas Carr's Hierarchy of Innovation

Figure 11.76: Nicholas Carr's proposed "hierarchy of innovation" [redrawn based on Carr 2015].

> As with Maslow's hierarchy, you shouldn't look at my hierarchy as a rigid one. Innovation today continues at all five levels. But the rewards, both monetary and reputational, are greatest at the highest level (Technologies of the Self), which has the effect of shunting investment, attention, and activity in that direction. We're already physically comfortable, so getting a little more physically comfortable doesn't seem particularly pressing. We've become inward looking, and what we crave are more powerful tools for modifying our internal state or projecting that state outward. An entrepreneur has a greater prospect of fame and riches if he creates, say, a popular social-networking tool than if he creates a faster, more efficient system for mass transit. The arc of innovation, to put a dark spin on it, is toward decadence.

> One of the consequences is that, as we move to the top level of the innovation hierarchy, the inventions have less visible, less transformative effects. We're no longer changing the shape of the physical world or even of society, as it manifests itself in the physical world. We're altering internal states, transforming the invisible self. Not surprisingly, when you step back and take a broad view, it looks like stagnation—it looks like nothing is changing very much. That's particularly true when you compare what's happening today with what happened a hundred years ago, when our focus on Technologies of Prosperity was peaking and our focus on Technologies of Leisure was also rapidly increasing, bringing a highly visible transformation of our physical circumstances.

Economist Tyler Cowen noted the decline in innovation and attributed it to several factors [Cowen 2011]. Most prominently, he said that the United States had already consumed all of the low-hanging fruit of technologies that could be readily developed. When viewed from the perspective of the history of science, it would seem unlikely that Cowen's argument is truly correct, that there truly are no more potential new technologies within humanity's current reach. For example, the classical world overlooked Hero's steam engine and its revolutionary potential, the steam era overlooked both gasoline internal combustion engines and the electrical revolution, nineteenth century physics overlooked both relativity and quantum physics, and classical biology overlooked the mechanisms and potential applications of DNA. If the rate of revolutionary innovations has slowed, it seems far more probable that the slowdown is due much more to deficiencies in the current innovation system, rather than to the actual absence of potential new technologies within our grasp.

On the other hand, if a large fraction of our modern technologies originated from the earlier German-speaking research world (as described in this book), then a somewhat more narrow interpretation of Cowen's argument could be quite valid. The United States plucked the low-hanging fruit of inventions and discoveries made in the earlier German-speaking world, took those creations to their fullest potential, and greatly profited from them, but never invested sufficient money, time, and energy to grow large amounts of entirely new fruit for future harvests.

Cowen's other explanations are also enlightening: Innovation shifted first from truly revolutionary technologies to more easily developed, easily marketed consumer products, and then from widely useful (if mundane) products to dubious "innovations" that only benefit a chosen few, sometimes even at the expense of everyone else [Cowen 2011, pp. 7–10, 20–21]:

> In a figurative sense, the American economy has enjoyed lots of low-hanging fruit since at least the seventeenth century, whether it be free land, lots of immigrant labor, or powerful new technologies. Yet during the last forty years, that low-hanging fruit started disappearing, and we started pretending it was still there. We have failed to recognize that we are at a technological plateau and the trees are more bare than we would like to think. That's it. That is what has gone wrong. [...]
>
> Around the globe, the populous countries that have been wealthy for some time share one common feature: Their rates of economic growth have slowed down since about 1970. That's a sign that the pace of technological development has been slowing down. It's not that something specific caused the slowdown, but rather we started to exhaust the benefits of our previous momentum without renewing them. [...]
>
> The period from 1880 to 1940 brought numerous major technological advances into our lives. [...]

> Today, in contrast, apart from the seemingly magical internet, life in broad material terms isn't so different from what it was in 1953. [...] Life is better and we have more stuff, but the pace of change has slowed down compared to what people saw two or three generations ago.
>
> It would make my life a lot better to have a teleportation machine. It makes my life only slightly better to have a larger refrigerator that makes ice in cubed or crushed form. We all understand that difference from a personal point of view, yet somehow we are reluctant to apply it to the economy writ large. But that's the truth behind our crisis today—the low-hanging fruit has been mostly plucked, at least for the time being. [...]
>
> A fundamental way to put the point is this: *A lot of our recent innovations are "private goods" rather than "public goods."* Contemporary innovation often takes the form of expanding positions of economic and political privilege, extracting resources from the government by lobbying, seeking the sometimes extreme protections of intellectual property laws, and producing goods that are exclusive or status related rather than universal, private rather than public; think twenty-five seasons of new, fall season Gucci handbags.
>
> The dubious financial innovations connected to our recent financial crisis are another (perhaps less obvious) example of discoveries that benefit some individuals but are not public goods more generally. A lot of the gains from recent financial innovations are captured by a relatively small number of individuals.

Note that there is considerable overlap among the economics-based arguments of Tyler Cowen, Nicholas Carr, and Jan Vijg: the **supply** of truly revolutionary scientific innovations is much less now because there has been an insufficiently strong and insufficiently widespread **demand** for revolutionary scientific innovations.

Summary of decline

As a final perspective on how much the U.S. innovation system has changed, in 1940 MIT professor Vannevar Bush showed President Franklin Roosevelt a one-page proposal outlining his multi-year, multi-billion-dollar plan for a new federally funded R&D system that would include the Manhattan Project, radar, and all other defense-related research projects. Roosevelt heard and approved the proposal in less than 15 minutes [Zachary 1997a, p. 112].

In contrast, nowadays even a professor's $100,000 proposal to the National Institutes of Health for modest experiments by some graduate students involves writing a detailed grant application that may be over 100 pages long, consumes several person-months to assemble, requires submitting extensive data and references to prove that the proposed experiments will definitely produce the intended results before they are even officially begun, can take over a year to pass through NIH administrative offices and peer review committees, and might stand less than a 10% chance of being funded after all of that. (Moreover, the very low success rate of proposals means that a research group might have to write 10 or more such proposals each year in hopes of getting just one funded, and writing that many proposals every year is a truly massive and enormously expensive diversion of personnel away from doing any of the actual research described in the proposals.)

Chapter 12

Learning from the Creators

Ich habe auf eine geringe Vermuthung eine gefährliche Reise gewagt und erblicke schon die Vorgebürge neuer Länder. Diejenigen, welche die Herzhaftigkeit haben die Untersuchung fortzusetzen, werden sie betreten und das Vergnügen haben, selbige mit ihrem Namen zu bezeichnen.

Upon a small conjecture I have ventured on a dangerous journey and already behold the foothills of new lands. Those who have the courage to continue the quest will enter those lands and have the joy of putting their name on them.

Immanuel Kant. 1755.
Allgemeine Naturgeschichte und Theorie des Himmels, Vorrede
[*Natural History and Theory of the Heavens*, Foreword].

Section 12.1 summarizes the major findings of Chapters 1–11.

Section 12.2 then applies that information to offer suggestions for:

> 12.2.1. Whole state or national innovation systems that would like to increase their production of revolutionary research.
>
> 12.2.2. Individual companies, organizations, or laboratories that would like to pursue more innovative research.
>
> 12.2.3. Individuals now trying to pursue careers in innovative research in the existing state of the global system.
>
> 12.2.4. Scholars who would like to further study the past, present, and potential future of revolutionary creators and creations.

Finally, Section 12.3 presents an afterword to encapsulate the vision for this book.

12.1 Summary of the Creators, Their Creations, and Their Approaches

As covered in Chapter 1, the motivation for this study follows from a series of logical steps, with many accompanying assumptions and limitations that are freely acknowledged (see Section 1.2.3 for a much longer and more detailed list):

1. Based on data and analyses from authors cited in Section 1.1, compared to earlier times, the modern research system appears to have produced fewer revolutionary innovations per year, or at least fewer revolutionary innovations per year per person in the system, or fewer innovations per year per amount of money spent on the system. (This study does not argue that the modern research system has produced no revolutionary innovations.)

2. Having concluded that the modern innovation rate has declined, this study proceeds on the assumption that it is possible that the modern innovation rate **can** be increased, or in other words that we have not simply encountered physical limits on innovation.

3. Moreover, this study operates on the assumption that the modern innovation rate **should** be increased, or the belief that at least on balance, new innovations will improve people's lives and are morally and socially desirable.

4. Rather than trying to reinvent the wheel, this study focuses on examining already proven ways to promote innovation. It does not consider new, unproven methods to promote innovation, although other scholars certainly should propose and evaluate new methods as well.

5. Among those proven ways to promote innovation, this study specifically considers past innovation systems. (Nevertheless, other scholars should and are evaluating various current innovation systems worldwide, and there is much to learn from those studies.)

6. Out of all past innovation systems, this study focuses on the predominantly German-speaking world of the nineteenth and early twentieth centuries, which admittedly is a topic with very fuzzy spatial, temporal, and intellectual boundaries. Based on the evidence in Chapters 2–9 and the appendices, I believe that world was the most innovative; at the very least it was **one of** the most innovative systems and thus worthy of detailed examination. This study is not intended to make an argument for nationalist or ethnic bragging rights. I highly recommend that readers of this book seek out or even conduct their own studies of scientific innovations from other places and times.

7. This study assumes that we can identify useful methods that promoted innovation in the earlier German-speaking world, yet it is at best a concise overview of a vast field encompassing the actions of thousands of scientists and engineers across many countries during two centuries, as well as investigations into that time period by countless subsequent scholars. I do not mean to imply that innovation systems in the earlier German-speaking world were ever perfect or even unique, or that all of their innovation-promoting factors could or should be applied to the modern world. In no way is this study an argument that the Third Reich had inherently superior scientific research approaches. For reasons of length, this study cannot even begin to address the large number of related ethical questions that are already covered in detail

by many other authors; I highly recommend that all readers seek out those books and study them.[1]

8. The ultimate objective of this study is to make these methods of improving innovation available to the modern world. In order to maximize the potential audience, longevity, and impact of this study, I decided to make the final document freely available on the internet instead of publishing it as a printed book, which might be expensive and difficult to obtain and might rapidly go out of print, as so many of the cited references have.

9. Because the body of information on German-speaking innovators is both so large and so incomplete, this book cannot help but be incomplete and imperfect. I would welcome any suggestions for improvements to future editions. At the very least, hopefully this book will spur discussion, learning, and further work in the important areas that it covers.

Scientists and engineers who were trained in the German-speaking world of the nineteenth and early twentieth centuries produced a wide range of discoveries and inventions that have shaped our modern world, including:

- Biomedical advances from genetics to antibiotics (Chapter 2 and Appendix A)
- Chemical breakthroughs from color film to synthetic rubber (Chapter 3)
- Discoveries about the Earth and our universe from continental drift to stellar distances (Chapter 4)
- Revolutionary physics from relativity to quantum mechanics (Chapter 5)
- Electrical inventions from semiconductors to computers (Chapter 6 and Appendices B–C)
- Mechanical systems from automobiles to submarines (Chapter 7)
- Nuclear reactions and applications from fission to fusion (Chapter 8 and Appendix D)
- Aerospace vehicles from jet planes to moon rockets (Chapter 9 and Appendix E)

Although other authors have studied the history of some of those creations and creators in detail, and Chapters 2–9 and the appendices shed additional light on others, much more work is needed to elucidate the full range and details of the contributions made by the German-speaking research world.

As discussed in Chapter 10, one may identify common factors within the German-speaking world that facilitated the success of those creators and creations. These factors promoted greater freedom to pursue longer-term and riskier potential innovations, and they included:

1. Science was socially glorified, from children's activities and amateur science clubs to prestigious jobs and government-lauded scientific heroes.
2. A century-long steady exponential increase in funding gave scientists, employers, and sponsors much more freedom to pursue higher-risk and/or longer-term research.
3. Many Ph.D. students were encouraged to propose their own research topics and to pursue them independently.
4. Scientists received their final degrees nearly a decade earlier in life, and independent research funding up to two decades earlier, than modern scientists do.
5. Scientists who made major contributions to multiple disciplines, and fraternization among scientists from different disciplines, were much more common than in the modern world.
6. Instead of peer review, an autocratic yet farsighted scientific management culture of "enlightened despots" granted stable jobs and funding to the most promising creators and creations.
7. Both scientists and sponsors used a systems analysis approach to focus on the most important problems and the most effective innovations to address those problems.
8. The lack of natural resources spurred the creation of a wide range of innovative alternatives.
9. International rivalry (both economic and military) was a powerful driving force for innovation.
10. German-speaking companies were less afraid of losing their own innovations to each other than of being outstripped by foreign countries, giving them a strong motivation to innovate.

From Chapter 11, the modern world eagerly adopted the creations of the earlier German-speaking world, yet ultimately largely forgot both the creators and the systemic approaches that had made such creations possible. Over the course of waves that occurred before, during, and after the Third Reich, all of the creations, most of the creators, and some of the systemic approaches were transferred from the German-speaking world to the United States and other countries in a German scientific diaspora. Those countries spent many decades fully perfecting and mass-producing the innovations that had been created by the earlier German-speaking world, resulting in our modern world of jet aircraft, electronics, and pharmaceuticals. Most of the creators who had already died or who remained in German-speaking areas were largely forgotten by the non-German-speaking world, which often mistakenly attributed their creations to whichever non-German-speaking individuals or organizations had acquired their technical information. Most of the creators who emigrated out of German-speaking areas led well-funded but quiet lives perfecting their creations and were also ultimately forgotten; only a few, such as Albert Einstein, Edward Teller, and Wernher von Braun, sought or received lasting fame. Especially during the 1940s–1960s, the United States and other countries practiced some of the general approaches that had made the earlier German-speaking world successful, thereby cultivating new innovators and innovations of their own.

By the 1970s, most of the German-speaking creators had retired or died, their creations had been refined to the point of diminishing incremental returns, and global research systems had abandoned most of the German-like practices they had adopted, significantly reducing their efficiency at producing entirely new innovators and innovations. The Cold War as a strong motivating force for innovation had also greatly relaxed around 1970, and most of the truly revolutionary new innovators (or innovations) that were produced by the global research system found it increasingly difficult to obtain proper support as time went by. From the 1990s onward, with the Cold War over and officials both public and private haggling over every research dollar while spending recklessly in other areas, the academic, corporate, and government research sectors each became increasingly dysfunctional in their own ways. As a result, even though the modern world has far more researchers, funding, and political stability than the earlier German-speaking world, it is difficult to identify as many revolutionary innovations that have been wholly developed by that modern system as those examples listed in Chapters 2–9 and Appendices A–E.

In 1946, the U.S. Department of Commerce wrote a press release that compared the German and U.S. approaches to research and explained what the United States could learn from the German model (see p. 5067). Most of those observations are still highly relevant three-quarters of a century later [NARA RG 40, Entry UD-75, Box 3, Folder Press Releases, The Chemical Problem in Germany]:

> The picture in scientific and chemical fields of development has long been very competitive and often retarded by the lack of financial assistance. Many of the industries of the United States while progressive on the production line have been quite willing to accept the benefit of the research and development of others, but not bothering to maintain research units of their own.
>
> Many of the chemical achievements now in use are the result of the research and development accomplished in other countries. While the United States enjoys the privilege of a school system that can and does provide numbers of young scientists, well versed in their particular fields, few are employed by industry at salaries commensurate with their skill. Consequently, the young scientific mind resolves the problem as one of mis-selection [of a career], so therefore, seeks and obtains more remunerative positions outside of their field causing a complete dislocation of their academic achievements.
>
> The German government and German industry had an entirely different attitude toward their scientifically trained men. The research and development work accomplished in the past decade will attest the value of subsidizing the scientists in the form of annuities and awards, not only for completed work but generous support of an idea from its embryonic imaginary state, through the laboratories, pilot plant, to the final production stage.
>
> In an emergency such as this country has just passed through, the United States was very fortunate that it could and did regiment the outstanding scientific brains of the country to undertake the modernization of the materials and warfare. Production lines and basic raw materials plus natural resources played as important a part as did science, yet one without the other would and could have proved quite ineffectual.
>
> The German industry and their subsidized scientists early realized that their natural resources were insufficient and the raw materials that could be imported would not be depended upon, nor were they readily obtainable. The problem was placed before

the German scientist, with the result that synthetic materials were produced, such as the industries in the United States never considered feasible, profitable, probable or possible.

Research and development work in Germany was concentrated in the larger industries of the I. G. Farbenindustrie caliber by grants made to the teaching staffs of universities and scientists of independent laboratories. The larger industries in turn were subsidized or controlled by the government.

Many tens of millions of dollars were expended in the U.S., not lavishly nor extravagantly during the war years, but much of the monies thus expended could have been more advantageously used had the work of research and development been protracted rather than immediately required as a war expedient. [...]

The inherent German love of gadgets, these investigators found, has produced a nation of gadgeteers and inventors. This is fostered by broad thorough elementary education in the mechanical and manual arts and by their system of apprenticeship training and has largely been instrumental in bringing about German development. [...]

The investigators were deeply impressed by the large pool of skilled mechanics upon whom Germany could draw. Their system of training the youth in mechanics, and shop practice, and familiarizing them with all kinds of modern tools had much to do with Germany's ability to wage such a devastating war against so many powerful nations. The same abilities and skills could be used for the increased production of the civilian products needed in peaceful pursuits. [...]

The most striking feature of the work the Germans performed for the development of their war material is undoubtedly the extremely high scientific order of their researches. In many fields they were pioneering and the outstanding results they achieved may, beyond doubt, be attributed to the long range provisions and the scientific approach on which they based their programs and the wealth of refined solutions they investigated in their research laboratories with the well-known German thoroughness.

12.2 Lessons from the Creators

Based on the perspective accumulated in Chapters 1–11, this section will offer suggestions for state or national innovation systems that would like to increase their production of revolutionary research (Section 12.2.1), for individual organizations or laboratories that would like to pursue more innovative research (Section 12.2.2), for individuals now trying to pursue careers in innovative research in the existing state of the global system (Section 12.2.3), and for scholars who would like to further study the past, present, and potential future of revolutionary creators and creations (Section 12.2.4).

12.2.1 Lessons for State, National, and Global Innovation Systems

Just as the nations of the earlier German-speaking world, as well as the United States during the 1940s–1960s, adopted policies that bred, supported, and rewarded revolutionary innovators and innovations, a modern nation or the entire global system could implement some of those proven policies. Many of these methods could even be adopted by an individual state (such as California or Massachusetts) within a nation. Based on the analysis of the earlier systems in Sections 10.2 and 11.2, those policies that a modern state or nation could consider (suitably adapted for modern times) include:

1. Science, science teachers, and science researchers were idolized and well funded in the German world, and also during the 1940s–1960s in the U.S. system, from children's activities and amateur science clubs to prestigious jobs and government-lauded scientific heroes. The social and financial status of science, science teachers, and science researchers should be elevated greatly beyond where they currently are in the modern world:
   (a) Better quality and greater variety of educational science experiment kits for children should be produced and more widely advertised and used.
   (b) Student science competitions (especially ones like science fairs that emulate real scientific research) should be given much greater emphasis, and the winners of those competitions should be publicly praised and rewarded at least as much as student athletes.
   (c) The salaries and working conditions of science and other teachers should be improved in order to attract very talented people to those positions and to recognize and reward the most effective teachers.
   (d) Important new scientific discoveries and inventions should be given much more coverage (comparable to or greater than that of sports stars and popular culture celebrities) in television news programs, movies, online video and audio programs, newspapers, magazines, and popular internet sites.
2. The highly innovative German-speaking world experienced exponential growth of research funding throughout its entire history until 1945, and the very productive period of the U.S. system during the 1940s–1960s also had exponential funding growth. Much greater freedom from funding pressures during those periods promoted much greater freedom to support longer-term, higher-risk, and potentially revolutionary innovators and innovations.
   (a) Although exponential funding growth cannot continue indefinitely, many nations or states could certainly afford to invest much more of their money in advanced research

and development than they do currently. For example, U.S. federal funding for R&D as a percent of GDP in 2017 was only around one-third of what it had been in the 1960s, and is expected to continue to decline.

(b) Even without having permanent exponential funding growth, governments could implement policies that would emulate the most important effects of such growth. Specifically, the number of graduating students trained in science research should be very close to the number of available permanent job positions, as it has been during periods of exponential funding growth, not far larger than the number of available permanent job positions as it is now.

(c) Increasing the number of temporary positions such as postdoctoral positions and internships would only put more young scientists into a holding pattern without either solving the fundamental mismatch between the number of scientists and the number of permanent jobs, or allowing those scientists to be independently productive.

(d) If the number of permanent job positions cannot be increased due to national fiscal constraints, the number of graduating students seeking science and engineering research careers should be decreased by motivating some students to seek other majors and other jobs, while still strongly encouraging the most creative students to pursue majors and careers in science and engineering research.

(e) If the amount of available funding and permanent job positions better matched the number of graduating students and career researchers, scientists would be able to spend much more of their time and energy doing productive research, and much less of their time and energy pursuing elusive funding and positions.

(f) If the amount of available funding and permanent job positions were much closer to the number of graduating students and career researchers, it would be much more acceptable to sponsors, institutions, and the scientists themselves for researchers to pursue longer-term work without an immediately demonstrable payoff, as well as more innovative higher-risk work that would be less guaranteed to yield results than very incremental, low-risk work. It would be much easier for the system to gamble that some of the funded researchers and projects would ultimately pay off and some would not, and to deem those stakes acceptable.

(g) Just as the above steps would increase freedom for academic and government researchers to pursue longer-term and higher-risk research, government could take steps to promote more long-term and/or higher-risk research in companies as well. Improved tax, patent, regulatory, or other government incentives could make it much more advantageous for companies to spend more of their money on research, and much more lucrative for the first company that develops any given major innovation, thereby encouraging companies to invest more of their capital in research, and specifically to put a greater fraction of it into longer-term, more innovative R&D.

(h) To conclude this topic, increased funding can be helpful but is not sufficient by itself. Doubling the R&D spending would not do much good if that simply yielded twice as many esoteric and repetitious papers in publicly inaccessible journals from academia, twice as many smart phone apps and erectile dysfunction pills from industry, and twice as much bureaucracy at government laboratories. The most important factor is not just providing more money, but rather providing scientists more freedom from the burden of proposals, from career woes, from the present focus on short-term results, and from the current bias toward very low-risk work.

3. Many German-speaking students were trained from an early age to be very creative and self-reliant researchers and inventors. Once they reached the universities, many (though certainly not all) German-speaking students were actively encouraged to come up with their own original Ph.D. thesis topics and to pursue that research independently, with loose mentorship from their Ph.D. advisors. That seems to have been true to some extent in the early U.S. system as well. In contrast, most modern U.S. students come up through an assembly line of rote science classes, are finally assigned a specific thesis topic and methods by their Ph.D. advisor, and then spend multiple postdoc jobs doing specific assigned work as well. If and when those scientists finally obtain an independent position, they do not have any expertise proposing and conducting truly innovative research.

    (a) Olympic gymnasts and concert pianists train from a very early age for their ultimate goal. It would be ludicrous to expect young people to simply watch Olympic gymnasts or concert pianists from the sidelines for decades, then finally step on stage for the first time in their 40s and be successful Olympic gymnasts or concert pianists themselves. It is equally ludicrous for the modern scientific system to hope to train revolutionary scientific innovators in that same fashion.

    (b) Science students in the modern world should be trained from an early age to be very creative and self-reliant researchers, using methods such as science kits for younger children and science fairs for older children, as already mentioned.

    (c) For university theses, students should be allowed and in fact strongly encouraged to select their own research topic and methods.

    (d) Research advisors should provide as much advice and assistance as is necessary (but only what is necessary) to ensure that their students are pursuing productive research topics using suitable methods.

    (e) Research advisors at universities should not use students as unpaid or low-wage labor to benefit the advisors' own research grants or lists of publications. Rather, advisors should do their own research work themselves, or hire actual paid employees to help them do the work.

4. Scientists in the earlier German-speaking world received their final degrees approximately a decade earlier in life, and independent research funding up to two decades earlier, than modern scientists do. Scientists in the early U.S. research system also received their degrees and funding earlier than modern scientists, although not as early as those in the former German-speaking world.

    (a) The average age at which scientists receive their final degree and are able to work independently should be greatly reduced. Lowering that age back toward the early to mid-twenties now would increase the number of years during which scientists could be productive, and in particular it would greatly increase the number of youthful working years during which those scientists have the greatest creativity, the most energy, and the fewest non-research obligations.

   (b) The average age at which scientists receive their Ph.D. should be lowered by decreasing the redundancy between high school and undergraduate courses, streamlining graduate education, and making sure that graduate research is shorter and more focused on a Ph.D. thesis (not work by the graduate student on unrelated projects and papers that primarily benefit the thesis advisor or that simply pad the student's résumé for an overly competitive job market).

   (c) The average age at which Ph.D. scientists obtain their first real job position and their own research funding should be lowered by eliminating postdoctoral positions and internships. That change would allow new doctoral graduates to proceed directly to stable, well-paying jobs where they could be maximally creative and productive. Although institutions may claim that postdoctoral positions provide valuable mentoring to young scientists, in practice the postdoctoral positions are much more about providing a pool of highly skilled, low-wage labor to lab supervisors than any essential mentorship or further education.

5. Individuals who made major contributions to multiple disciplines, and routine fraternization among individuals from different disciplines, were rather common in the German-speaking world, and still occurred quite a bit in the early U.S. research system. In this modern era of microspecialization, the older interdisciplinary mindset should be revived and rewarded:

   (a) The modern world should train, support, and reward at least some percentage of multidisciplinary scientists who can make major contributions in multiple fields, apply knowledge and methods from one field to another, and use their broader view to guide fields of research away from less productive areas and toward more productive ones.

   (b) All scientists should be strongly encouraged to make their research comprehensible to people outside their field, and to interact with scientists in other fields in a variety of environments. Increased interactions among individuals from different disciplines would also help cross-pollinate ideas among different fields, and help scientists in different fields obtain greater perspective.

6. In the German-speaking world and the early U.S. research system, "enlightened despots" were able to spot potentially revolutionary innovators and innovations and grant them long-term financial and political support. While there is certainly a place for methodical peer review, entrusting virtually all funding and hiring decisions to peer review risks overlooking those creative new scientists and ideas that are so revolutionary that they cannot easily and immediately get broad consensus from the scientific status quo.

   (a) Rather than allotting all funding (and effectively most jobs) by peer review, the modern research system should set aside some percentage of research funding to be allocated by enlightened despots who are good at identifying potentially revolutionary innovators and innovations.

   (b) Such enlightened despots should have the clear authority to grant financial and political support to any people or projects they deem worthy, and to grant that support for many years without having to demonstrate that there is an immediate payoff, or even that all funded research will eventually pay off.

   (c) How enlightened despots with the best discernment would be selected is an unresolved question. In both the German-speaking world and the early U.S. research system, they either arrived at their positions by some combination of luck and force of will, or else they were hand-picked by previously established enlightened despots. Those methods are not perfect but could be tried now, or perhaps a better way to select the best enlightened despots could be found.

   (d) Wherever possible, any remaining peer review should be done by reviewers unaware of the researchers' names and affiliations, so that they can more fairly evaluate the actual research in question.

7. In the German-speaking world and in the early U.S. research system, a systems analysis approach was used to great effect in order to identify the most important problems and the most effective innovations to address those problems, and to help focus scientific personnel and funding in those directions. This systems analysis approach was employed by both scientists and sponsors. In contrast, the modern world appears to be too subject to the whims of vast numbers of self-interested individuals whose overriding priority is to maximize outputs other than innovation, such as their number of publications or their stock price. It would be beneficial to re-emphasize a systems analysis approach.

   (a) Systems analysis should be widely taught and practiced in schools and universities.

   (b) By using systems analysis, key decision makers in government, industry, and academia could help focus more resources on the most important problems and potential solutions.

   (c) If individual scientists were taught to practice systems analysis, they could use that method to guide their careers and their research projects in more promising directions, and to ensure that no potentially useful regions of the conceptual "phase space" had been overlooked.

8. The very limited availability of natural resources was a major factor in driving innovation in the German-speaking world. It was much less of a factor in the early U.S. research system, although the United States did adopt many of the synthetic products that had been developed in the earlier German-speaking world.

   (a) Now that the world is much more conscious of its dwindling natural resources and the rising long-term costs of climate change, pollution, and waste, government-funded programs and government regulations for industrial programs should prioritize the development of very innovative methods of reducing the consumption of natural resources and minimizing the creation of waste products.

   (b) Such policies would not only improve the environment in which we and future generations must live, but would also be a strong driver of a wide range of new and very beneficial innovations.

9. International rivalry, largely military but also economic, was the driving force behind the historical German-speaking world and the early U.S. research system. Without seeking a return to militarism and war, a healthy sense of competition among states or nations could be useful:

   (a) Peaceful economic rivalry and even regional pride (as in sports competitions) could be employed constructively to motivate states or nations to accelerate their research and development programs.

   (b) Existing high-tech innovation centers (small geographical areas in which R&D is concentrated) that support and promote interactions among programs they contain could be strengthened, and rival high-tech centers could be created to compete for the best scientists, projects, research funding, and economic income from resulting inventions and products. [See Gruber and Johnson 2019 for a strong and detailed argument for many regional high-tech innovation centers.]

10. For more than a century, German-speaking companies were much more afraid of being outstripped by foreign countries than of losing their own innovations to each other. Likewise, in the 1940s–1960s, U.S. companies were much more afraid of losing first to the Axis countries and then to the Soviet Union than to each other. In both cases, that mindset toward competition gave the companies a strong motivation to innovate.

    (a) Companies should view very innovative, longer-term R&D as a worthwhile investment in staying ahead of competitors, not a financial liability whose resulting products could be copied by competitors that did not have to spend any money on their own R&D.

    (b) Improved tax, patent, regulatory, or other government incentives could make it much more lucrative for the first company that develops any given major innovation, and/or less lucrative for copycats.

    (c) Suitably structured tax incentives could also provide strong inducements for companies to put much more of their capital and annual income into research and development (and other useful things, including infrastructure and employee salaries/benefits), instead of enormous cash and stock payouts that only benefit a small number of individuals.

12.2.2 Lessons for Individual Organizations and Laboratories

While it might be difficult to persuade an entire nation to reform its scientific system, individual universities, companies, government laboratories, or other organizations could readily adopt certain practices related to those that made the older German-speaking world so successful.

Many of the strategies already listed in Section 12.2.1 could be implemented in a scaled-down, much more local fashion:

1. An organization should do anything within its power to improve the social and financial status of science research. An organization should strongly encourage, support, recognize, and reward innovative research among its own members. It should also promote its scientific innovation and accomplishments to the outside world, and sponsor educational science programs and student competitions in the outside world. The costs of these internal and external promotional programs would be handsomely repaid by both the increased productivity of the organization's own members and the organization's enhanced prestige and desirability as viewed by the outside world.

2. Universities should better match the number of graduating students and career researchers with the amount of funding and permanent job positions, so that scientists do not waste much of their time and energy pursuing elusive funding and positions. With a better balance between people and jobs, and therefore reduced pressure for all job occupants to have maximum short-term productivity, each organization should make room for at least some of its members to spend at least some of their time pursuing longer-term work without an immediately demonstrable payoff, as well as more innovative higher-risk work that would be less guaranteed to yield results than very incremental, low-risk work. While some of those bets would not pay off, others could pay off with revolutionary results that could prove highly lucrative over the long run.

3. In individual organizations from K-12 programs and universities to companies and government laboratories, young scientists should be trained from the very beginning to be creative and self-reliant researchers. Such investments of time, resources, and institutional trust in the younger scientists could ultimately yield very large returns.

4. Individual universities should implement programs in which the average age at which scientists receive their doctoral degrees is in their early to mid-twenties; such programs would be so attractive to students that those universities would have their pick of the best applicants. Organizations should also implement programs to provide jobs and stable funding for extremely young but highly creative scientists. These steps would greatly increase the number of productive working years during which those scientists have the greatest creativity, the most energy, and the fewest non-research obligations. Again, the longer-term payoffs for organizations that take these steps could be tremendous.

5. An organization should train, recruit, and reward at least some percentage of multidisciplinary scientists who can make major contributions in multiple fields, apply knowledge and methods from one field to another, and use their broader view to guide work away from less productive areas and toward more productive ones. All scientists within an organization

should be strongly encouraged to make their research comprehensible to people outside their field, and to interact with scientists in other fields in a variety of environments, in order to cross-pollinate ideas among different fields.

6. An organization should set aside at least some percentage of research hiring and funding decisions to be determined by enlightened despots who are good at identifying potentially revolutionary innovators and innovations. Such enlightened despots should have the clear authority to grant financial and political support to any people or projects they deem worthy, and to grant that support for many years without having to demonstrate that there is an immediate payoff, or even that all funded research will eventually pay off.

7. By using systems analysis, the leadership of an organization could help focus more of the organization's resources on the most important problems and potential solutions. If individual members of the organization were taught to practice systems analysis, they could use that method to guide their careers and their research projects in more promising directions, and to ensure that no potentially useful regions of the conceptual "phase space" had been overlooked.

8. In the face of dwindling natural resources and the rising long-term costs of climate change, pollution, and waste, organizations should prioritize the development of very innovative methods of reducing the consumption of natural resources and minimizing the creation of waste products.

9. Organizational pride and rivalry with other organizations should be used constructively to motivate innovation within an organization, and to promote interactions among the scientists and projects within the organization in order to maximize the potential of each one.

10. Companies should view very innovative, longer-term R&D as a worthwhile investment in staying ahead of competitors, not a financial liability whose resulting products could be copied by competitors that did not fund their own R&D. They should lobby federal and state governments for improved tax, patent, regulatory, or other incentives that would make it much more lucrative for the first company that develops any given major innovation. They should also lobby for structured tax incentives that would reward companies that put more of their capital into research.

In addition to smaller-scale local versions of those strategies, additional steps could be taken by individual labs and organizations:

11. In the German-speaking world, the cost of a university education was very low and not an obstacle, and students were generally able to go straight through their university education without having to spend significant time and energy working other jobs to try to pay for it. With no student loan debt, after graduation those students could immediately use their degrees to earn a good income. A university education in the United States in the 1940s–1960s was also quite affordable. In contrast, nowadays a university education in the United States leaves a student and also the student's family with enormous debts (up to many hundreds of thousands of dollars) that can last for decades or even a lifetime. It is imperative to eliminate this financial obstacle and burden.

   (a) Universities with large endowments should use income from those endowments to make their educational programs tuition-free for any students they admit. By doing so, they would get their pick of the best students in the world.

   (b) Whatever factors have been driving U.S. tuition costs to astronomical levels (ever-multiplying armies of non-teaching administrators and staff, professors who are paid very highly yet leave most or all of the teaching to adjunct faculty or grad students, overpriced and overly showy buildings and athletic facilities, etc.) were never essential in the past. They can certainly be eliminated in these times when online students all around the world can watch videos of the world's best lecturer on a given topic, read an excellent electronic textbook on any subject, or complete automated assignments and exams on their computers at essentially negligible cost.

12. In the German-speaking world and in the early U.S. research system, many young scientists had already produced revolutionary inventions and discoveries by the time they were in their mid-twenties. Many modern students could do so too if they were given enough time, resources, and support.

    (a) For relatively very little money, individual laboratories or a philanthropic foundation could identify students who have done the most innovative, independent research in high school science fairs such as the International Science and Engineering Fair (ISEF) and Science Talent Search (STS), and offer them summer or part-time positions in college where they would be completely free to develop and pursue their own ideas (with appropriate supervision and assistance as needed).

    (b) Such students should be able to hone and exercise the innovative research talents they have already developed, instead of having to leave those behind to spend years of drudge work slowly working their way up the ladder (undergraduate students following instructions from graduate students following instructions from postdocs following instructions from a tenure-track assistant professor following instructions from the university department and from research sponsors).

    (c) Organizations offering temporary positions to such students should not impose any intellectual property agreements on their new ideas, in order to avoid creating legal and financial entanglements that could strangle the students' ideas in the crib as soon as the students leave their temporary positions.

13. Universities are places where students go to learn; therefore, universities should select and evaluate their professors largely on the basis of their teaching ability, and support and honor those who invest the most energy and talent in their teaching. In the earlier German-speaking world, research was important but never eclipsed, let alone eliminated, the responsibility of professors to be good teachers. If it is too difficult for modern professors to balance teaching and research, some professors' positions could be designated primarily for teaching, and some primarily for research. In that case, universities would need to avoid the pitfalls of giving higher status to research professors than to teaching professors, or of using student tuition to fund non-teaching research professors.

14. Employers, sponsors, and journals should evaluate scientists' research proposals and results on the basis of their true quality, innovation, and significance, not on the basis of the sheer

volume of a scientist's papers or name recognition of people or places involved in the work. In the German-speaking world, a lone and obscure patent clerk without a Ph.D. (Einstein) could submit a highly insightful paper, have it be promptly published and carefully listened to, and change the world as a result. How feasible would that be in the modern system?

   (a) Peer reviewers could evaluate papers and research grant proposals more fairly if the reviewers did not know the authors or institutions involved in the research. For that approach to work properly, it might also be necessary to avoid clues in the cited references, resource lists, or other sections that might give the reviewers too much information about the authors or institutions.

   (b) Scientists should be evaluated based on the actual scientific quality and importance of their work, as they generally were in the German-speaking world and in the early U.S. research system. Evaluating scientists primarily on the basis of the sheer quantity of their publications or where they appeared is a concept that arose in the modern system and that does not give priority to the types of work, scientists, or research projects that will actually have the greatest impact.

15. Scientists should strive to make their work more comprehensible and relevant to scientists in other fields, to government, and to the general public. Whereas scientists now seemingly seek to invent more and more unnecessarily specialized language and isolated subfields, scientists of all fields once rubbed shoulders in the coffeehouses and symposia of the German-speaking world.

16. Corporate leaders, managers, and workers should be rewarded on the basis of their contributions to the long-term potential and success of the company, not on the basis of tomorrow's stock price or next year's product. In the German-speaking world and in the United States of the 1940s–1960s, companies deliberately recruited, supported, rewarded, and profited from leaders and scientists with successful long-term visions for revolutionary products.

17. In the German-speaking world, government laboratories such as the Kaiser Wilhelm Institutes and the military labs were strong centers of innovation that could very effectively focus on revolutionary research because they were free of both the teaching obligations of universities and the product manufacturing obligations of companies. In the United States of the 1940s–1960s, government-run laboratories such as Los Alamos, NASA centers, and U.S. Air Force, Navy, and Army research labs enjoyed similar advantages and supported revolutionary innovators and innovations. Yet in the modern United States, many government-run and government-funded laboratories now struggle through 70+ years of accumulated red tape to continue working on technologies that have not been revolutionary for 70+ years.

   (a) Any remaining truly essential functions that government laboratories perform regarding those now extremely mature technologies should be transferred to much cheaper, simpler contractors. Current government laboratories should be drastically restructured or otherwise replaced with new government laboratories to eliminate their red tape and to refocus them on new potentially revolutionary technologies.

   (b) Modern government laboratories should make the most of their potential to combine the best qualities of academia and industry and to avoid the worst qualities of each, just as such laboratories did in the German-speaking world and in the early U.S. research system. In principle, government laboratories can avoid the teaching and constant paper-publishing obligations of academia while emulating its focus on longer-term research, and also avoid the obligations of industry to produce lucrative products in the short term while retaining industry's focus on applications instead of pure basic research.

18. Whereas many modern organizations view their employees as interchangeable and inexpensive components to be replaced frequently and at will, older German organizations viewed their employees as a valuable long-term resource to be cultivated (p. 1985). Modern organizations should adopt that same view, carefully hiring the best job applicants; paying and treating them very well; giving them the training, resources, time, freedom, and support they need to be as successful as possible; and recognizing and rewarding their accomplishments. Having the best employees with the best resources will help an organization be as innovative and productive as possible in the long term, and will also help it continue to hire and support new employees to maintain that tradition.

12.2.3 Lessons for Individual Scientists and Engineers

While individual scientists and engineers are very unlikely to be able to exert control over the whole research system or even part of it, they can control their own careers. Based on this study comparing the earlier innovation systems with the present system, options and suggestions for individuals are given below and summarized graphically in Fig. 12.1.

1. Everyone should be very cognizant that the modern innovation system is divided into academic, corporate, and government research sectors, and that in general each is currently suffering from deep-seated problems outlined in Sections 1.1 and 11.3. If someone is interested in science but would like to avoid those problems by pursuing a career not in scientific research and development, there are a large number of potentially fulfilling and potentially lucrative careers that involve science but not R&D. To give just a few examples, one might consider:
    (a) Becoming a medical doctor, nurse, veterinarian, or other healthcare worker.
    (b) Practicing law in science-related areas such as writing patent applications or negotiating technology licensing agreements.
    (c) Pursuing a business or finance career in science-related areas, for example by evaluating scientific ideas for venture capital firms, or by earning business or finance degrees to work in corresponding positions in science-related companies.
    (d) Teaching science or math subjects at K-12 grade levels or at a community college.
    (e) Producing and/or selling scientific or medical tools, equipment, or supplies, or even educational scientific kits and toys.
    (f) Writing or offering science advice for science fiction films, television shows, novels, comics, etc.
2. Because the problems in the modern innovation system are so pronounced, only someone who feels strongly personally compelled to pursue a career in scientific R&D should do so. After having studied the problems in the academic, corporate, and government research sectors, if someone finds one of those sectors preferable to the other two and is willing to endure its known difficulties for the duration of a career, that can be a clear and well-informed choice:
    (a) Some individuals will be most willing to live with the problems in academic research.
    (b) Some individuals will be most willing to live with the problems in corporate research.
    (c) Some individuals will be most willing to live with the problems in government research.
    (d) If someone feels personally compelled to pursue an innovative scientific career and yet is not satisfied with the current state of the academic, corporate, and government research sectors, the available options involve harder choices and murkier information.

3. One possibility for intrepid young innovators is to seek areas where R&D funding for new projects might be more readily available than is the case in the mainstream system:
    (a) Some corner of the existing research system may still be conducive to revolutionary innovation, especially if it is nurtured and protected by an enlightened despot like those of earlier times—perhaps a particularly farsighted corporate CEO/owner/investor/senior manager, philanthropist, university administrator, or defense or intelligence sponsor.
    (b) Some field that is so incredibly old, so new, such a novel combination of existing fields, or so offbeat that it is not filled to overflowing with peer-reviewed competitors may afford better opportunities.
    (c) There might be better funding prospects for new innovators and innovations in those few countries that still have steadily increasing investments in R&D.
4. Another possibility, though only for the very courageous individual, would be to try to improve some specific part of one of the existing research sectors (academic, corporate, or government). Several guidelines should be kept in mind:
    (a) Before proceeding down this path, one should very carefully select which specific part of which research sector to try to improve, and equally carefully plan exactly how that improvement could be realistically accomplished.
    (b) One should expect fierce resistance from the existing system at every step of the way.
    (c) One should recognize from the outset that there is a high probability any effort at reform or improvement will fail, no matter how well intentioned, carefully planned, and diligently executed it might be.
    (d) Anyone advocating for improvement should seek supportive allies at all levels from high government positions to physical plant maintenance. That is sound advice for any pursuit, but especially critical if a reformer is to have any hope of success.
5. If someone feels personally compelled to pursue innovative R&D and is not satisfied with (or cannot access) any of the options outlined above, the remaining possibility is to try to pursue a research career outside of the official sectors. Several keys are important to make this sort of career path possible:
    (a) In the absence of financial support from the academic, corporate, or government research sectors, it is necessary to seek and obtain alternative sources of financial support for independent scientific work. The nature of those alternative sources will depend upon an individual's specific circumstances, interests, and opportunities, but could range anywhere from taking a normal job that pays well but allows enough outside time for research (e.g., Swiss patent clerk), to marrying into wealth, to accepting internet donations or crowdfunding.

   (b) It is critical to identify and focus on projects that can be accomplished with limited labor (often only that of the individual, or even just some fraction of the individual's time) and very limited equipment, supplies, and other resources. Those considerations will likely limit any work to theoretical analyses or at best very small-scale experimental research.

   (c) Two or more individuals interested in the same or similar areas might pool their time and resources in order to accomplish more and to provide mutual encouragement. Among other possibilities, one might establish or join a "maker space," amateur science club, scientific co-op, or other organization.

   (d) No matter how high the quality of an unaffiliated individual's work might be, that person will likely have great difficulty getting proper consideration from scientific journals, government patent offices, or corporate technology licensing offices. Therefore, without necessarily giving up on those establishment methods for output, one should seriously consider alternative methods of output for any significant scientific results, including freely releasing results on the internet without any possibility of monetary gain in hopes of maximizing the ultimate impact of those results.

6. Based on the examples of successful creators from the earlier research systems, modern individuals should follow these practices both for finding/creating a suitable job (which requires innovative problem solving in its own right) and for conducting innovative research:

   (a) No matter how limited your time, resources, and options may be, practice innovation right now and every day after that, rather than hoping to start later on down the road. Brainstorm for new ideas for innovative research projects, make a list of the ideas, and add to that list every time you think of a new idea, day or night. Constantly consider various ways in which those ideas could be analyzed theoretically, computationally, or experimentally, or how they could be developed in part or in whole into models or prototypes. Seek outside input to correct or supplement your ideas, but do not simply copy what others say or do. To be as successful as possible at scientific innovation, you must practice it from as early an age as possible, and as much as possible (just like any other skill).

   (b) Constantly seek out resources and opportunities to test or develop any of the innovative ideas from your list, and keep your eyes open for opportunities that may arise spontaneously.

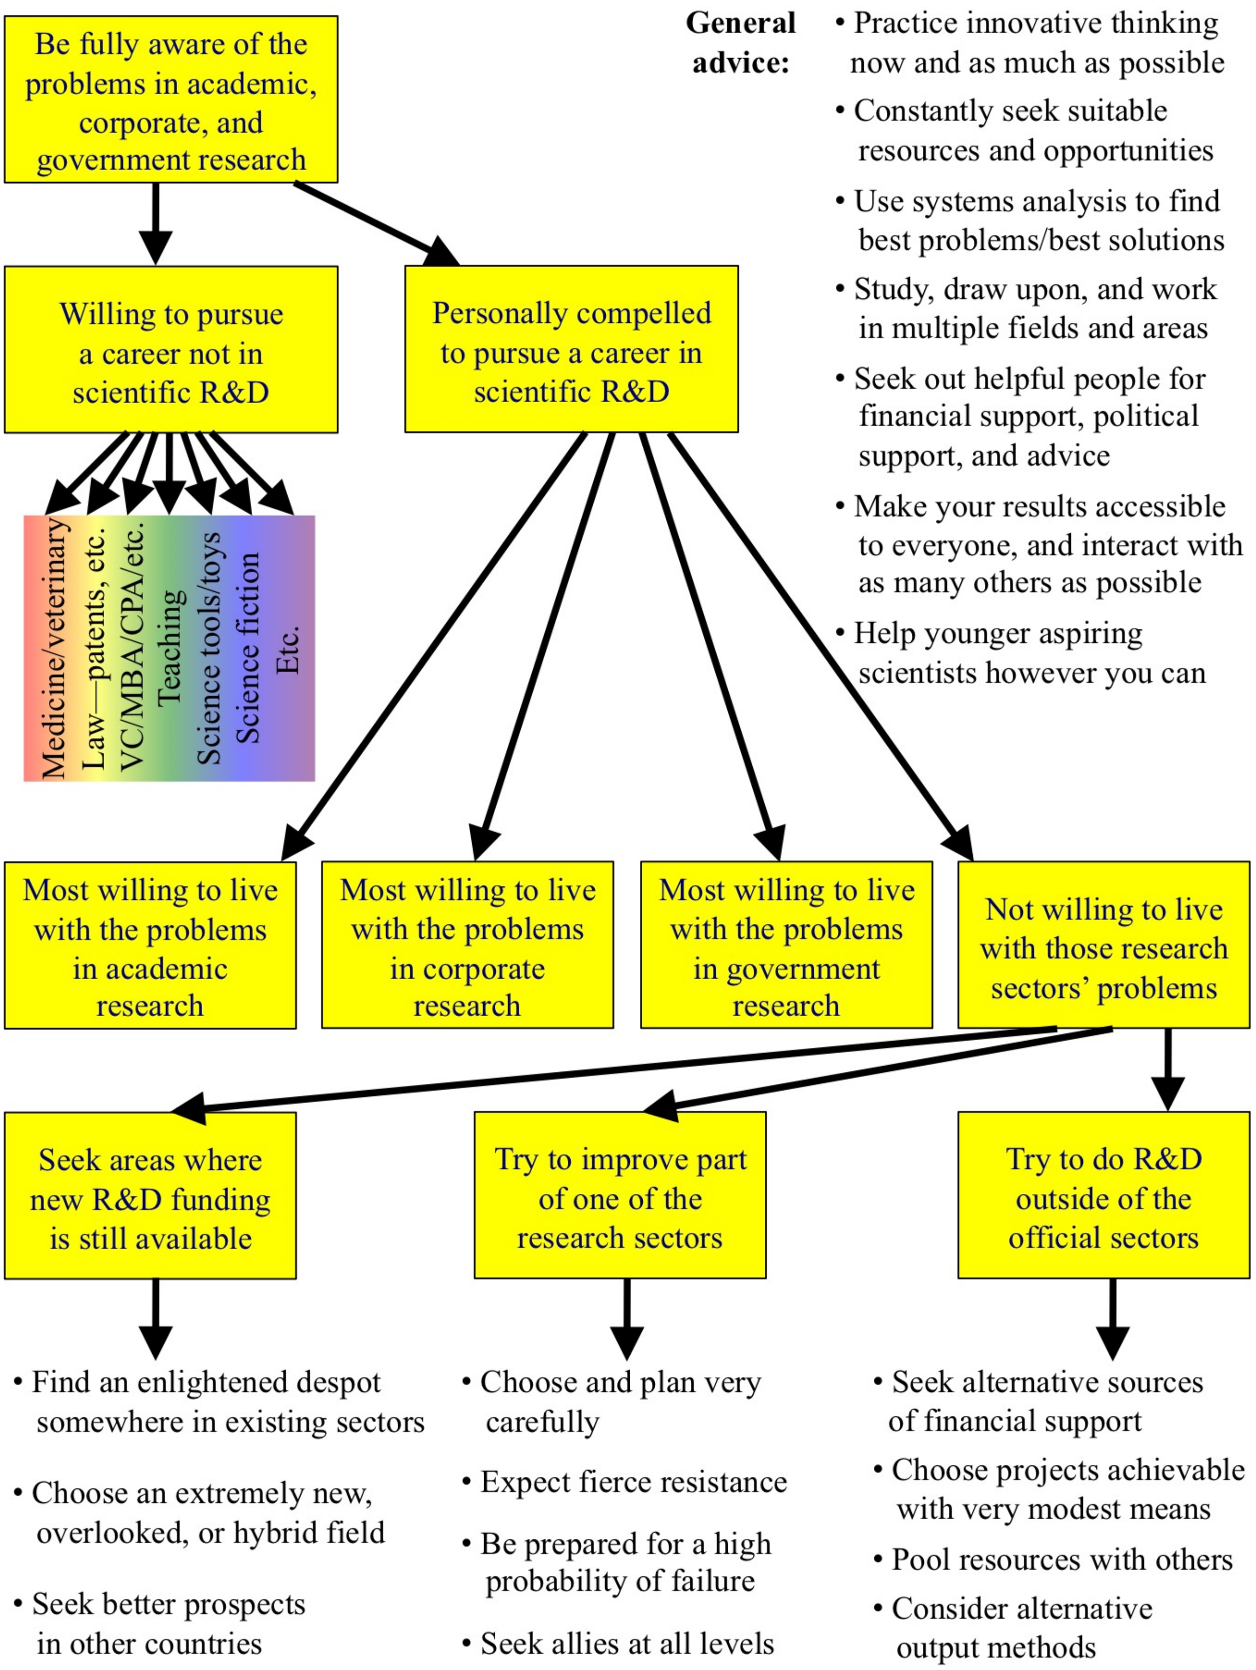
   (c) Employ a top-down systems analysis approach [Zwicky 1969] to identify first the most important problems to work on, and then the range of possible solutions for those problems, and finally out of those possibilities the best solutions for the best problems that one could pursue, all subject to the constraints of your own particular talents, resources, and opportunities.

   (d) Study multiple fields, and multiple areas within a field. Having multidisciplinary expertise can enable you to make contributions in different fields (as opportunities arise), achieve new results by applying knowledge and methods from one field to another, and use your broader view to guide your work away from less productive areas and toward more productive ones.

(e) Actively seek out people who are as close to being enlightened despots as you can find—individual people who (i) are most inclined to support the sort of innovative research you would like to do and (ii) are best able to offer you financial support, political support, and/or useful advice.

(f) Present your research in such a way that it will be comprehensible to scientists outside that particular field and also to non-scientists. Along the way, actively maximize your interactions with scientists in other fields in a variety of environments, in order to cross-pollinate ideas.

(g) Wherever and however possible, help inspire, train, support, and reward aspiring scientists who are younger than you. Although you may have few resources, a younger aspiring scientist will probably have even fewer than you do. You could be the closest thing to an enlightened despot that they will find.



Be fully aware of the problems in academic, corporate, and government research
Willing to pursue a career not in scientific R&D
Personally compelled to pursue a career in scientific R&D
Medicine/veterinary
Law—patents, etc.
VC/MBA/CPA/etc.
Teaching
Science tools/toys
Science fiction
Etc.
General advice:
• Practice innovative thinking now and as much as possible
• Constantly seek suitable resources and opportunities
• Use systems analysis to find best problems/best solutions
• Study, draw upon, and work in multiple fields and areas
• Seek out helpful people for financial support, political support, and advice
• Make your results accessible to everyone, and interact with as many others as possible
• Help younger aspiring scientists however you can
Most willing to live with the problems in academic research
Most willing to live with the problems in corporate research
Most willing to live with the problems in government research
Not willing to live with those research sectors' problems
Seek areas where new R&D funding is still available
Try to improve part of one of the research sectors
Try to do R&D outside of the official sectors
• Find an enlightened despot somewhere in existing sectors
• Choose an extremely new, overlooked, or hybrid field
• Seek better prospects in other countries
• Choose and plan very carefully
• Expect fierce resistance
• Be prepared for a high probability of failure
• Seek allies at all levels
• Seek alternative sources of financial support
• Choose projects achievable with very modest means
• Pool resources with others
• Consider alternative output methods

Figure 12.1: Options for individual scientists and engineers.

12.2.4 Lessons for Scholars of Past, Present, & Potential Future Innovation Systems

Due to limitations of time, resources, and length, this study could only give an overview of some of the issues involved in revolutionary scientific innovation in the historical German-speaking world and in the United States. Issues that were briefly introduced in this study deserve to be investigated and written up in far more detail. Many related areas could not be addressed at all in this study, yet warrant thorough exploration in their own right. For convenience, all of these issues for further study may be categorized on the basis of whether they primarily focus on past, present, or potential future innovation systems.

Some questions that should be further investigated by scholars of past innovation systems include:

1. What factors helped or hindered revolutionary scientific innovation in the German-speaking world:
   (a) Prior to 1800?
   (b) From 1800 to 1945? Is there other evidence to support or refute the factors proposed in Chapter 10? Is there evidence for major factors that were not considered in Chapter 10? (See p. 2030 for some possibilities.)
   (c) After 1945 (on both sides of the Iron Curtain)?

   How could knowledge about those historical factors be applied to improve modern innovation systems?

2. What factors helped or hindered the U.S. innovation system:
   (a) Prior to the 1940s?
   (b) During the 1940s–1960s? Is there other evidence to support or refute the factors proposed in Chapter 11? Is there evidence for major factors that were not considered in Chapter 11? (See p. 2030 for some possibilities.)
   (c) After the 1960s? Is there other evidence to support or refute the factors proposed in Chapter 11? Is there evidence for major factors that were not considered in Chapter 11?

   How could knowledge about those historical factors be applied to improve modern innovation systems?

3. What factors helped or hindered the historical innovation systems in:
    - (a) United Kingdom?
    - (b) France?
    - (c) Russia/Soviet Union?
    - (d) Scandinavian countries?
    - (e) Italy?
    - (f) Japan?
    - (g) Other countries?

    How could knowledge about those historical factors be applied to improve modern innovation systems?

4. What were the major innovators, leaders, details, timeline, and maximum extent of the historical German-speaking world's contributions in:
    - (a) Molecular and cellular biology, including DNA, RNA, proteins, immunology, cancer, antibiotics, vaccines, fermentation, biotechnology, offensive and defensive biological warfare, etc.?
    - (b) Chemical weapons more advanced than tabun, sarin, and soman?
    - (c) Microelectronics, including diodes, transistors, laser diodes, other semiconductor devices, printed circuits, integrated circuits, computers, robotics, guidance systems, encryption systems, photocopiers, etc.?
    - (d) Directed energy technologies, including lasers, masers, ion beams, electron beams, neutron or other neutral particle beams, electromagnetic pulse, X-ray and gamma-ray beams, ultraviolet beams, infrared beams, microwave beams, acoustic beams, electric and/or magnetic railguns, etc.?
    - (e) Nuclear technologies, including fission reactors, fission weapons, fusion reactors, fusion weapons, nuclear aircraft propulsion, nuclear rocket propulsion, nuclear submarine propulsion, transuranic isotope production and characterization, etc.?
    - (f) Advanced aerospace technologies, including intercontinental jet aircraft, multistage rockets, intercontinental ballistic missiles, submarine-launched missiles, manned spacecraft, space planes and space shuttles, reentry systems, large liquid propellant rocket engines, solid propellant rockets, electric rocket propulsion technologies, and space stations?
    - (g) Other areas in biology and medicine?
    - (h) Other areas in chemistry and materials science?

   (i) Other areas in earth and space science?

   (j) Other areas in physics and applied mathematics?

   (k) Other areas in electrical and electromagnetic engineering?

   (l) Other areas in mechanical engineering?

   (m) Other areas in nuclear science and technology?

   (n) Other areas in aerospace engineering?

   Because Allied documentation (foreign scientist case files; Alsos, BIOS, CIOS, FIAT, JIOA, and NavTecMisEu reports; etc.) on German and Austrian research is so extensive yet only accessible as paper documents in a few national archives, it would be extremely helpful if the German and Austrian governments would fund scholars to photograph or digitize those documents and make them available on the internet. Such a step would greatly enhance the general understanding of all of the above areas.

5. How did family traditions, immigration status, and cultural backgrounds affect the production of creators?

   (a) What aspects of Jewish family life in the early German-speaking and U.S. systems, East Asian or South Asian family life in the modern U.S. system, or other family backgrounds resulted in a far larger percentage of creators having those backgrounds than was true for the entire population in those countries?

   (b) What aspects of being an immigrant, or the descendant of people who immigrated in a recent previous generation (for example, parents or grandparents), resulted in a far larger percentage of creators having that background than was true for the entire population in those countries?

   (c) What aspects of the general culture in various countries made it less likely that children of families that had been in those countries for many generations would become successful scientific innovators? What cultural aspects encouraged children to be less intellectually driven, or if intellectually driven less inclined toward a career in scientific research, or if scientists less creative or less successful?

6. For the most successful scientific enlightened despots in the German-speaking world, early U.S. system, or other research systems:

   (a) How did the system select the best despots and measure their success during their careers?

   (b) What criteria and methods did the best despots use to select the most promising new innovators and innovations?

   (c) What managerial, political, and financial methods did the despots use to ensure proper support for their own positions and for the scientists that they backed?

   (d) How did the system best support the despots and the scientists that they backed?

7. What were the major creators, creations, innovation methods, and transfer methods involved in transferring innovations from the German-speaking world to:

   (a) Other countries before the Third Reich?

   (b) Other countries during the Third Reich?

   (c) The United States after the Third Reich?

   (d) The Soviet Union after the Third Reich?

   (e) The United Kingdom after the Third Reich?

   (f) France after the Third Reich?

   (g) Other countries after the Third Reich?

Some questions that should be further investigated by scholars of present innovation systems include:

1. What factors help or hinder the current innovation systems in:
   (a) The United States?
   (b) China?
   (c) Japan?
   (d) Germany?
   (e) South Korea?
   (f) India?
   (g) France?
   (h) United Kingdom?
   (i) Russia?
   (j) Singapore?
   (k) Other countries?

   How could knowledge about those factors be applied to improve the innovation systems in other countries?

2. What fractions of modern corporate R&D funding are spent on:
   (a) Products for which some version and/or competitor is already on the market?
   (b) Products that reach the market within one, two, three, four, five, or more years?
   (c) Products that never reach the market?

   How do those figures compare to statistics from earlier times or from other countries? What do the results say about the current level of innovation, creative risk, and long-term planning in the modern corporate R&D system?

3. On average, how much time does a modern principal investigator at a government-funded and/or government-run laboratory spend on:
   (a) Actual research—designing and carrying out experimental or theoretical research?
   (b) Work that is not actual research—writing grant applications, writing up progress reports and papers, seeking bureaucratic approvals, attending meetings, etc.?

How do those results compare with statistics from earlier times or from other countries?

4. On average, how much time does a modern university professor spend on:
   (a) Actual teaching?
   (b) Actual research—designing and carrying out experimental or theoretical research?
   (c) Work that is not actual research or teaching—writing grant applications, meeting with sponsors or donors, writing up progress reports and papers, serving on peer review committees, attending other meetings, etc.?

   How do those results compare with statistics from earlier times or from other countries? What do the results say about the quality of education and research in the modern academic system?

5. What is the average age at which a modern principal investigator is truly free (in a position of long-term employment; provided with sufficient funding, equipment, labor, and time; etc.) to propose and pursue their own entirely original scientific research projects? How do those results compare with statistics from earlier times or from other countries?

6. Why has the average cost of university education (at least in the United States, and possibly in other countries) risen much faster than the inflation rate for several decades? What fractions of those increases went toward administrators, buildings, university endowments, direct improvements in teaching, direct improvements in research, direct improvements in student life, etc.?

7. Why has the average cost of K-12 and university textbooks (at least in the United States, and possibly in other countries) risen much faster than the inflation rate for several decades? If publishers can profitably sell much lower-priced “international editions” of those same books outside of the United States, why can or do they not profitably sell editions of those books within the United States for the same lower prices? Why are textbooks so much more expensive than other types of books, even other types of books that require the same level of detail and editing as textbooks?

8. What fraction of the scientific work published each year is freely available online without registrations, memberships, subscriptions, pay-per-article firewalls, conference costs, having to find or purchase a copy of a book or journal, etc.?

Some questions that should be further investigated by scholars of potential future innovation systems include:

1. In addition to lessons that can be learned from past or present innovation systems, what entirely new strategies can be devised for improving innovation systems? How could those strategies be tested at a smaller scale to measure and optimize their effectiveness and to minimize any negative consequences before implementing them at a large scale?

2. Given the capabilities of the internet and the desirability to minimize costs while maximizing the accessibility and quality of education, what is the best system for university-level education and degrees?

3. What are the most effective ways to inspire young students to want to become scientific innovators?

4. What are the best strategies for finding the most innovative students and giving them the skills, resources, support, and freedom to create revolutionary innovations?

5. Are there better alternatives for research funding decisions than peer review? If some fraction of research funding and hiring decisions were entrusted to scientific enlightened despots, what would be the best way to select despots with the greatest discernment and skill? Even letting successful despots select new despots could lead to a decline in quality, like the gradual decline of early Christian popes or the abrupt end of the “Five Good Emperors” of the Roman Empire.

6. Are there better alternatives for publication than the current system of peer review in (mostly) highly specialized journals? What are the best ways to disseminate researchers’ results while (a) enforcing standards for scientific quality, (b) making the results as widely and freely accessible as possible, and (c) reducing the glut of virtually unread and insignificant papers?

12.3 Afterword

I believe that the ability to create revolutionary scientific innovations is a noble and all-too-rare skill that has transformed the world (mostly for the better) over the past millennia, and that has the potential to further improve the world in the future. While a certain number of revolutionary scientific innovators can arise spontaneously in almost any environment and may sometimes find just the right opportunities to realize their creations, a far larger number of revolutionary innovators and innovations can be produced if there is a system that actively inspires and trains new revolutionary innovators, and then diligently supports and rewards them for developing revolutionary innovations. By researching, writing, and presenting this book, I have endeavored to offer what I hope is a new and useful perspective on the past, the present, and the possible future of systems for promoting revolutionary scientific innovation.

In science and engineering, it is helpful to represent complex signals or data as the sum of several different simple signals of steadily decreasing size and importance, with the simple individual signals sometimes interacting with each other in nonlinear and less easily predictable ways. Likewise, I believe it can be useful to view the complexities of history as the sum of many different simple forces and movements, from larger and more dominant ones to smaller and less significant ones; sometimes those simple individual historical forces interact with each other in nonlinear and less predictable ways.

The history of revolutionary scientific innovation covers the world, spans thousands of years, and includes countless individual larger and smaller forces as well as their nonlinear interactions. I have not even attempted to tackle that complete picture and that complete set of forces. Rather, I have endeavored to illuminate one of those individual forces, the predominantly German-speaking scientific world of the nineteenth and early twentieth centuries, which served as an engine for producing enormous numbers of revolutionary scientific innovators, who in turn produced huge numbers of revolutionary scientific innovations. I believe that most historians, scientists, and leaders have not had a proper understanding of the accomplishments, the methods, and the importance of that earlier German-speaking innovation engine.

Based upon data such as that summarized in this book, I would like to propose a theory, and to encourage others to consider it, modify it, prove it, disprove it, or offer alternatives to it:

> The German-speaking world of the nineteenth and early twentieth centuries was the strongest (though certainly not the only) engine for producing revolutionary scientific innovators during its time, and quite possibly even the strongest (but not only) such engine in all of history. That engine was carefully constructed and nurtured throughout the nineteenth and early twentieth centuries, but then was seriously damaged in 1933 and almost entirely dismantled in 1945.[2] Thus it ceased to produce many new revolutionary scientific innovators around

---

[2] The Third Reich drove out, fired, imprisoned, and/or killed a large fraction of the scientific innovators. Most of the remaining ones were mistreated and misused, even if some of their creations did receive lavish funding. The Third Reich also caused huge numbers of its students (many of whom would have become future scientists) and some of its existing scientists to die fighting in the war, made the schools and universities highly ideological and dysfunctional, and made scientists focus their energies solely on developing military projects without also refilling the research pipeline by training the next generation of innovators and making new discoveries in fundamental science. Even if the Third Reich had won the war, the German-speaking scientific world that had been so carefully cultivated by earlier generations would have been destroyed. As it was, the Third Reich lost, and most of the remaining scientists

> 1933–1945. (Rebuilding the German-speaking research world after 1945 took decades, and one could debate whether the rebuilt German-speaking research world more closely resembles the earlier German-speaking world or the rest of the postwar scientific world.)
>
> Newly educated and empowered revolutionary scientific innovators tend to have rather specific visions of the revolutionary scientific innovations that they would like to create and perfect. Succeeding waves of innovators that were produced by the German-speaking world throughout the nineteenth and early twentieth centuries created and perfected succeeding waves of microbiology discoveries, applied chemistry methods, earth science discoveries, physics theories, electromagnetic devices, mechanical inventions, and early aircraft. The final wave of revolutionary innovators produced by the German-speaking engine before its 1933–1945 decline and demise immediately fixed their sights on antibiotics and biotechnology, synthetic drug molecules and polymers, high-energy physics and cosmology, microelectronics and computers, sophisticated automobiles and submarines, nuclear reactors and nuclear weapons, and jets and rockets. Beginning during the period 1933–1945 and continuing for the remaining decades of their careers, that final wave of German-speaking scientific innovators made those visions a reality, the fabric of the modern world in which we now live.

I would also like to suggest two corollaries to my theory for people to debate, and I believe that they too are supported by data such as that presented in this book:

1. If the German-speaking engine of the nineteenth and early twentieth centuries had never existed, most of the revolutionary innovators it produced would never have existed, and they would never have been able to create their revolutionary innovations. In that case, the state of science and engineering in the modern world might have been many years or even decades less advanced than it currently is. (Naturally, some revolutionary German-speaking innovators would have found a way to develop and to succeed even in the absence of a nurturing system, and the rest of the world would have continued to produce some revolutionary innovators and innovations, although I believe at a slower rate.)

2. The world's primary engine for producing revolutionary scientific innovators was one of the least recognized casualties of World War II, yet perhaps the one with the longest lasting and most widespread consequences. If the German-speaking engine had not been damaged and dismantled in 1933–1945, but rather had continued to function or even to grow, the state of science and engineering in the modern world might be decades more advanced than it currently is. What revolutionary scientific innovations would have been conceived and developed by the wave of new revolutionary innovators that the fully functional German-speaking engine might have produced by 1960? By 1980? By 2000? Today? What revolutionary medicines and materials might we have developed by now? What power sources and vehicles might we have had by now? How far might human settlements have ventured into the oceans and into space by now? (Of course, even after the end of the German-speaking engine in 1945, the world continued to produce some new revolutionary innovators and innovations, yet I would suggest not at the same rate as what the German-speaking engine had produced or what it might have continued to produce.)

---

and all of their innovations were removed and divided among the Allied countries, which generally used them up for short-term gain instead of leveraging them as a long-term investment to help create and support large numbers of new revolutionary innovators.

Nevertheless, the ultimate purpose of this book is not to get lost pondering the possibilities of the past, but rather to contemplate potential strategies for the future. If the world previously constructed an effective engine for creating huge numbers of revolutionary scientific innovators and innovations, it can assemble another such engine, or maybe even a better engine, now. We need not debate whether it is possible to create such an engine of revolutionary innovation. We need not wonder how we might build such an engine. We just need to fully remember the Forgotten Creators, and to learn all that we can from them.

Appendices

Es läßt sich wohl behaupten, daß die Geschichte der Wissenschaften die Wissenschaft selbst sei. Man kann dasjenige, was man besitzt, nicht rein erkennen, bis man das, was andere vor uns besessen, zu erkennen weiß.

It can be argued that the history of science is science itself. One cannot recognize clearly what one has found until one knows what others found before us.

Johann Wolfgang von Goethe [Schwenk 2000, p. 7].

Appendix A: **Advanced Creations in Biology and Medicine** **p. 2305**

Appendix B: **Advanced Creations in Electrical Engineering** **p. 2653**

Appendix C: **Advanced Creations in Directed Energy** **p. 3019**

Appendix D: **Advanced Creations in Nuclear Engineering** **p. 3253**

Appendix E: **Advanced Creations in Aerospace Engineering** **p. 5185**

1. In order not to obscure the book's arguments by simply referring readers to numerous documents that may be difficult to obtain, relevant excerpts from a large number of key sources are presented in the appendices.

2. To make the contents computer-searchable for readers and internet search engines, most documents have been retyped (with annotations as appropriate) instead of being reproduced as photographs.

3. Where I have retyped documents, I have tried to preserve the formatting of the original documents (underlining, etc.) as much as possible.

4. To avoid variant spellings that would not come up in a computer text search, I have silently corrected some obvious typographical errors in some of the quoted source documents. U.S. and U.K. documents that were typed during and shortly after World War II were often careless in their spellings of the German names of people and places.

5. In order to avoid increasing the length of this already enormous book by a factor of several fold, I have abridged portions of the documents that seemed less relevant, as denoted by [...] in the quoted text.

6. Where I wanted to add emphasis to passages in quoted documents to draw the attention of readers, I have displayed those passages in red. Even passages not in red are relevant, though, which is why I have taken the time to type them up and include them too.

7. To add my own commentary regarding quoted documents yet clearly distinguish my commentary from the text of the source documents, [my commentary appears in blue text inside square brackets].

8. Key sources not in English are presented in both their original language and a parallel English translation.

9. Citations direct interested readers to the original sources of these documents in case readers would like to verify their authenticity and read them in full.

10. Each source quote has been placed in the most relevant section, but it may be germane to other sections as well, as indicated by cross-references.

Appendix A

Advanced Creations in Biology and Medicine

Was war also das Leben? Es war Wärme, das Wärmeprodukt formerhaltender Bestandlosigkeit, ein Fieber der Materie, von welchem der Prozeß unaufhörlicher Zersetzung und Wiederherstellung unhaltbar verwickelt, unhaltbar kunstreich aufgebauter Eiweissmolekel begleitet war.

What then was life? It was warmth, the warmth generated by a form-preserving instability, a fever of matter, which accompanied the process of ceaseless decay and repair of protein molecules that were too impossibly complicated, too impossibly ingenious in structure.

Thomas Mann. 1924. *Der Zauberberg* [*The Magic Mountain*]. Chapter 5.
English translation adapted from H. T. Lowe-Porter.

This appendix presents portions of archival documents from during and immediately after World War II. These documents suggest that Germany:

A.1. Had the largest and most advanced biotechnology programs in the world at that time.

A.2. Was developing neural interfaces to control prosthetic limbs and weapons systems.

A.3. Possessed a significant offensive program in biological warfare.

A.4. Discovered advanced V-series nerve agents during the war.

Much more archival research is needed to elucidate the complete history and accomplishments of these programs.

A.1 Biotechnology

[A commonly held view among historians of science is that biotechnology was a postwar U.S./U.K. invention and that the German-speaking world was very late and far behind in pursuing biotechnology. For example, historian of science Luitgard Marschall summarized this view of biotechnology in Germany [Szöllösi-Janze 2001, pp. 112–114]:

> Owing to their theoretical foundation in organic chemistry, the research and production methods of chemical synthesis were regarded already at the beginning of the twentieth century as extremely science-based and therefore as modern and innovative. Biotechnology, in contrast, was for a long time considered to be an empirical and backward production technique, just because of its lack of theory and science-based methods [...]
>
> [B]etween 1933 and 1945 biotechnological processes were used only to compensate the deficits of chemical syntheses. Biotechnology was thus relegated to special processing niches. However, this relegation of biotechnological processes in favour of chemical ones had already started prior to 1933 and, after 1945, it culminated in further retardation. This of course indicates a continuous process. Nevertheless, the development in the Third Reich demonstrated particular features which had a lasting influence on the further course of biotechnology. [...]
>
> The metaphor of technological trajectories provides a viable explanatory model for the development of industrial biotechnology in Germany. As is well known, the German chemical industry decided early on to follow the path of chemical synthesis [...] This decision proved to be extraordinarily successful and contributed to its gaining a leading position in synthetic organic chemistry. It had some opportunity costs, however: up to now the fact has been ignored that the early commitment to chemical synthesis and its intensive expansion was detrimental to the development of biotechnology. For a long period in the twentieth century biotechnology played the part of a 'loser technology'. Its academic and industrial development was neglected in Germany until the 1970s in favour of chemical synthesis.

As shown in this section and in Chapter 2, there is a large amount of evidence that biotechnology and molecular biology (including knowledge, tools, methods, and applications) were developed by the German-speaking world in the nineteenth and early twentieth centuries, then transferred to the United States, United Kingdom, and other countries:

1. German-speaking scientists invented and perfected instruments suitable for biotechnology:
    (a) Carl Zeiss (German, 1816–1888), Ernst Abbe (German, 1840–1905), and Otto Schott (German, 1851–1935) perfected diffraction-limited optical microscopes during the 1870s–1880s (p. 1270).
    (b) In 1902, Richard Zsigmondy (Austrian, 1865–1929) and Henry Siedentopf (German, 1872-1940) invented the ultramicroscope for determining particle sizes in colloids; see p. 1271.
    (c) August Köhler (German, 1866–1948) and Moritz von Rohr (German, 1868–1940) invented the ultraviolet microscope in 1904, as shown on p. 1272.

   (d) August Köhler and Henry Siedentopf invented the fluorescence microscope in 1908 (p. 1273). Fluorescence microscopes are now a widespread tool in biology laboratories because different cellular components can be labeled with different colors of fluorescent tags.

   (e) Karl Bratuschek (German?, 1865–1913) at the Zeiss company was apparently moving toward the development of phase contrast microscopy before his death [Wimmer 2017]. Frits Zernike (Dutch, 1888–1966) invented phase contrast microscopes in 1933, and they were mass produced by Zeiss (pp. 1274, 2474–2484).

   (f) In 1926, Hans Busch (German, 1884–1973) created the first electrostatic and magnetic lenses for electrons. From 1931 onward, four different groups, all in the greater Berlin area, built and demonstrated electron microscopes: Technische Hochschule Berlin, Siemens & Halske, Allgemeine Elektrizität Gesellschaft (AEG), and Manfred von Ardenne (German, 1907–1997). See pp. 1289–1295.

   (g) Fritz Pregl (Austrian, 1869–1930) developed micro-pipetting and micro-analysis tools and methods in the 1910s (pp. 473, 2320–2324).

   (h) Scientists from the German-speaking world invented and used centrifuges for a large range of applications from 1864 through World War II (pp. 2394–2399).

   (i) German-speaking scientists harnessed focused sound waves for a wide variety of applications, ranging from the first ultrasound imaging devices to ultrasonic sonicators to disrupt chemical solutions and molecules. Documents in Section C.4 demonstrate that those technologies were developed and successfully demonstrated in Germany and Austria during the 1930s and early 1940s, and then directly transferred to other countries in 1945, leading to modern acoustic and ultrasound devices.

   (j) Robert Havemann (German, 1910–1982) invented spectrophotometers no later than 1936 (pp. 2378–2388). He also conducted important research on colloids (p. 719).

   (k) P. H. Keck (German?, 19??–19??) invented luminometers no later than 1943 (pp. 2446–2447).

   (l) In 1940 or earlier, Andreas Lembke (German, 1911–2002), Hellmuth Bayha (German?, 19??–19??), Karl Krammer (German?, 19??–19??), Eugen Sauter (German?, 19??–19??), and other scientists developed and successfully implemented methods of using intense ultraviolet light to sterilize liquids and other materials (pp. 2367–2373).

2. German-speaking scientists discovered most of the major types of bacteria and developed antiseptics and antibiotics to prevent or treat bacterial infections:

   (a) With newly improved microscopes (Section 6.9), it became much easier to see organisms as small as bacteria. However, a remaining problem was that most bacteria are essentially clear, and surrounded by essentially clear liquid or other sample material. Therefore, scientists in the German-speaking world developed methods that stained bacteria different colors than the surrounding sample material, making it much easier to visualize their shapes and identify them under the microscope. Scientists who developed important early microscope staining techniques for bacteria included Karl Weigert (German, 1845–1904), Paul Ehrlich (German, 1854–1915), and Robert Koch (German, 1843–1910), as shown on p. 166.

   (b) In 1872, Ferdinand Cohn (German, 1828–1898, p. 167) created the modern classification system for bacterial shapes (spheres or cocci, rods or bacilli, spirals or spirochetes, etc.).

   (c) Based on the earlier stains, Hans Christian Gram (Danish but worked and made his discovery in Germany, 1853–1938, p. 166) developed the "Gram staining" method in Berlin in 1884 while working with Carl Friedländer (German, 1847–1887, p. 174). Gram staining is still widely used to distinguish between bacteria with two different types of cell walls, "Gram-positive" bacteria that turn purple with this technique and "Gram-negative" bacteria that turn red. The ability to distinguish between Gram-positive and Gram-negative bacteria, and among bacteria with different shapes, was and remains a powerful method to identify bacteria under the microscope (p. 163).

   (d) Robert Koch (German, 1843–1910) and many other German-speaking scientists discovered most of the common pathogenic types of bacteria (pp. 164–176).

   (e) In 1847 (approximately two decades before Joseph Lister), Ignaz Semmelweis (Austrian, 1818–1865) developed and demonstrated antiseptics to prevent bacterial infections (pp. 164–165).

   (f) Paul Ehrlich (German, 1854–1915) discovered Salvarsan, the first antibiotic, in 1909 and successfully used it to treat syphilis (p. 187).

   (g) Gerhard Domagk (German, 1895–1964) discovered and demonstrated sulfa antibiotics, the first broad-spectrum antibiotics, in 1932. The large sulfa family of antibiotics is still widely used today (p. 188).

   (h) Ernst Chain (German, 1906–1979) purified penicillin in 1940 (p. 189), taking penicillin from an effect that could only be demonstrated in Petri dishes to an effective antibiotic that could be mass-produced and administered to people.

   (i) Richard Kuhn (Austrian, 1900–1967) produced and tested synthetic antibiotics such as "3065" during World War II, using massively parallel chemical synthesis and testing to carry out very modern methods of structure-activity relationship (SAR) optimization of the drug molecules (pp. 190, 2325, 2352, 2389, 2406–2411).

3. German-speaking scientists developed methods of culturing and utilizing prokaryotic (bacteria) and eukaryotic (yeast, animal, and plant) cells:

   (a) Working together with Robert Koch, Julius Petri (German, 1852–1921) invented Petri dishes in 1881. In that same year, spouses Fanny Hesse (born of German parents in the United States, lived in Germany, 1850–1934) and Walther Hesse (German, 1846–1911) developed agar nutrient gel to fill those dishes [Brock 1999; Schlegel 2004]. The agar provides a solid surface that does not decay to a messy liquid as microorganisms grow on it. Agar-filled Petri dishes are now virtually ubiquitous in biology laboratories for culturing microorganisms.

   (b) By 1890, Carl Wehmer (1858–1935) was using yeast fermentation to produce citric acid, fumaric acid, and other substances [Benninga 1990]. See pp. 2315–2319.

   (c) Otto Röhm (German, 1876–1939) and his company Röhm and Haas developed industrial-scale culture of microorganisms to produce and purify enzymes (proteases, starch hydrolases, pectinases, lipases, etc.) for many different commercial applications during the period from 1906 through World War II (pp. 2448–2452).

   (d) Franz Schardinger (Austrian, 1853–1920) used bacterial fermentation to produce acetone (1903–1904). See p. 180 for some of his publications demonstrating his methods and results.

   (e) In 1910, Chaim Azriel Weizmann (Belarus, educated and worked in Germany and Switzerland, 1874–1952) began internationally popularizing Schardinger's methods of using bacterial fermentation to produce acetone (p. 183). (Sometimes international credit was given to Weizmann for popularizing these methods, but not to Schardinger for first inventing, demonstrating, and publishing these methods.)

   (f) In the early twentieth century, bioreactors for the continuous liquid culture of microorganisms were developed by scientists at Benkiser, Boehringer, I.G. Farben, Phrix, Röhm and Haas, and other German companies and laboratories (pp. 2326–2339, 2401–2404, 2412, 2448–2452).

   (g) In the 1940s, the use of bioreactors for the continuous liquid culture of microorganisms was internationally popularized by German-speaking refugees such as Ernst Chain (German, 1906–1979, working in the United Kingdom) and Leo Szilard (Hungarian, 1898–1964, working in the United States, p. 183), and also by Allied investigators who wrote numerous reports on the German biotechnology industry (pp. 2401–2404, 2412).

   (h) German-speaking scientists developed methods of isolating cells from larger organisms and using "tissue culture" methods to keep those cells alive and even get them to reproduce under laboratory conditions (p. 87). Wilhelm Roux (German, 1850–1924) conducted the first animal cell tissue culture experiments in 1885, removing medullary plate cells from a chicken embryo and keeping them alive in culture for 13 days. Paul Grawitz (German, 1850–1932) experimented with tissue culture of additional animal cell types in the 1890s. Gottlieb Haberlandt (Austrian, 1854–1945) developed plant cell tissue culture and also discovered totipotency, the ability of some "stem" cells to give rise to any type of specialized cell in an organism, in 1902.

4. German-speaking scientists made key discoveries regarding viruses:

   (a) Peter Plett (German states, 1766–1823) developed and successfully demonstrated a cowpox-based vaccine for smallpox virus beginning in the late 1780s, and first reported his results in 1790. Edward Jenner (English, 1749–1823) rediscovered the same thing several years later, and published his first results in 1798. Yet Jenner became famous as the discoverer of smallpox vaccine, and Plett has been virtually forgotten [Plett 2006]. See p. 194.

   (b) German-speaking scientists discovered and characterized tobacco mosaic virus from 1886 onward (pp. 195–196).

   (c) From 1897 onward, German-speaking scientists discovered and characterized foot-and-mouth disease virus, produced therapeutic antibodies for it, created vaccines for it, demonstrated a tissue culture model for it, and developed immunoassays for it (pp. 197–199).

   (d) German-speaking scientists discovered and characterized poliovirus from 1908 onward (pp. 200–201).

   (e) German-speaking scientists pioneered the study of bacteriophages, viruses that infect bacteria, and made numerous other contributions to virology (pp. 200–202).

5. German-speaking scientists discovered and analyzed nucleic acids (DNA and RNA):

   (a) Gregor Mendel (Austrian, 1822–1884) discovered the rules of genetics using plants he grew at his monastery (1864 or earlier), and meticulously documented his discoveries and explanations in a lengthy book. See p. 96.

   (b) In 1869, Johannes Friedrich Miescher (Swiss, 1844–1895) extracted and purified DNA (which he called nuclein) from human white blood cells and suggested that DNA is involved in heredity (p. 97).

   (c) Walther Flemming (German, 1843–1905) made detailed observations of chromosomes during mitotic cell division from 1873 onward (p. 98).

   (d) Beginning in the 1870s, Albrecht Kossel (German, 1853–1927) showed that DNA and RNA contain five different bases (adenine, cytosine, guanine, thymine, and uracil), demonstrated that those bases are connected via linkages of sugars and phosphates, and isolated and studied proteins that bind to nucleic acids in the nucleus (histones and other accessory proteins). See p. 99.

   (e) No later than 1907, Wilhelm Weinberg (German, 1862–1937) discovered the equilibrium distribution of alleles (different versions of a gene) within a population of a species (p. 100).

   (f) In 1933 or earlier, Ernst Caspari (German, 1909–1988), Alfred Kühn (German, 1885–1968), Adolf Butenandt (German, 1903–1995), and other researchers in Germany analyzed mutations in insects and discovered that individual genes encode individual proteins (pp. 101–102).

   (g) In a revolutionary 1935 paper, Max Delbrück (German, 1906–1981), Nikolai Timoféeff-Ressovsky (Russian but worked in Germany 1925–1945, lived 1900–1981), and Karl Günter Zimmer (German, 1911–1988) at the Kaiser Wilhelm Society in Berlin described and demonstrated the structure of chromosomal DNA, methods and consequences of inducing point mutations in DNA, and forced genetic recombination of different pieces of DNA (p. 103).

   (h) In or before 1940 (under wartime conditions and 13 years before the discovery by Rosalind Franklin, Francis Crick, and James Watson), Hans Friedrich-Freksa (German, 1906–1973) proposed that the structure of DNA is double-stranded with electrostatic attraction between complementary sequences on the two strands (p. 104).

   (i) By 1940–1942, and also despite the severe wartime hindrances, Gerhard Schramm (German, 1910–1969) identified the genome of the tobacco mosaic virus as RNA, showed that its protein subunits are identical, and mutated the RNA to create mutant proteins (p. 105).

   (j) Many other German-speaking scientists also made significant contributions to knowledge about DNA and RNA (pp. 106–112).

6. German-speaking scientists pioneered the study, diagnosis, prevention, and treatment of cancer:

(a) During the period 1889–1891, Erik Johan Widmark (Swedish but closely coupled to the German-speaking research world, 1850–1909) and Friedrich Hammer (German, 1860–1943) demonstrated via a series of experiments that ultraviolet light causes suntans and sunburns, and that those effects could be reduced by coating the skin with a protective layer of certain natural plant extracts (p. 125).

(b) Leopold Freund (Austrian, 1868–1943) and Eduard Schiff (Austrian, 1849–1913) developed and employed radiation therapy to kill tumors from 1896 onward (pp. 1509–1510). Freund wrote the first medical textbook on radiation therapy in 1902 and published it in 1903 [Leopold Freund 1903]. Translations of the book in English and other languages were published in 1904, so Freund truly founded and shaped the field of radiation therapy worldwide.

(c) Theodor Boveri (German, 1862–1915) realized in 1902 that cancer can be caused by pro-mitotic (cell-division-inducing) mutations from radiation, chemicals, or viruses (pp. 113–117).

(d) In 1922, Leopold Freund and Josef Maria Eder (Austrian, 1855–1944) invented the first chemical sunscreen, which was marketed as Antilux (p. 126).

(e) Fritz Lickint (German, 1898–1960) began medical studies of smokers vs. nonsmokers in the 1920s, published evidence that smoking causes cancer in 1929, and published a >1200 page medical book on the detailed pathology caused by smoking in 1939 (p. 118). His discoveries led to public health campaigns against smoking, first in Germany and much later worldwide [Haustein 2004].

(f) German-speaking scientists identified specific carcinogens from the 1870s through World War II and developed methods to control and prevent exposure (pp. 113–124, 2375–2374).

(g) By the early 1940s, German-speaking scientists developed therapeutic antibodies against cancer-related antigens (pp. 2354–2359). Such therapeutic antibodies are currently one of the most modern and most effective methods of treating cancers in patients.

(h) German-speaking scientists also made many other significant contributions to knowledge about cancer (pp. 119–124).

7. German-speaking scientists characterized and harnessed proteins and enzymes:

   (a) Wilhelm Kühne (German, 1837–1900) was one of the first scientists to study proteins in detail (p. 128). He discovered trypsin, a digestive enzyme or protease that degrades other proteins, studied proteins in muscle and rhodopsin in human photoreceptor cells, and in fact coined the word “enzyme” (p. 138).

   (b) Franz Hofmeister (Austrian, 1850–1922) established many methods of protein chemistry that are still used today (Fig. 2.42). He discovered the peptide bonds in proteins, the effect of various salts on proteins, differing protein solubilities, methods of protein purification, and methods of protein crystallization [Abernethy 1967].

   (c) Beginning in the 1870s, Albrecht Kossel (German, 1853–1927) showed that proteins are composed of amino acids, and isolated and characterized the individual amino acids (p. 140).

  (d) German-speaking scientists invented immunoassays (228). Max von Gruber (Austrian, 1853–1927) discovered the agglutination reaction, in which antibodies and pathogens clump together, in 1896. Rudolf Kraus (Austrian, 1868–1932) used the agglutination reaction to create an antibody assay for specific bacterial precipitins in 1897. August von Wasserman (German, 1866–1925) used similar methods to create a complement fixation test for syphilis bacteria in 1906.

  (e) In 1912, Leonor Michaelis (German, 1875–1949) and Maud Menten (Canadian, worked in Germany, 1879–1960) developed experimental and theoretical methods to analyze the chemical reaction rates of enzymes (p. 142).

  (f) Otto Röhm (German, 1876–1939) pioneered the industrial production, purification, and use of enzymes (proteases, starch hydrolases, pectinases, lipases, etc.) for applications such as leather production (1906), washing detergents (1914), pharmaceuticals (1920), and juice processing (1934). See pp. 2353, 2445, 2448–2452.

  (g) Starting in the 1910s, Max Bergmann (German, 1886–1944) created methods of determining the amino acid sequences of natural proteins and of artificially synthesizing proteins with specific amino acid sequences (p. 130).

  (h) German-speaking scientists played leading roles in discovering and understanding the enzymes involved in mitochondria, cellular respiration, and related metabolic reactions (pp. 156–159).

  (i) In the 1930s and early 1940s, German-speaking scientists developed several egg protein substitutes that consisted of protein extracted, purified, and processed on an industrial scale from cultured yeast, animal blood plasma (Plenora), fish (Eiweiss), and milk (Milei). See pp. 2326–2339, 2390–2393, 2400–2401.

  (j) Max Perutz (Austrian, 1914–2002) developed and demonstrated methods of determining detailed three-dimensional protein structures such as hemoglobin (p. 144).

  (k) German-speaking scientists also made many other contributions to knowledge about proteins and enzymes (pp. 135–137).

8. In addition to all of the above production, German-speaking scientists produced and purified a wide range of other biomolecules for many different applications:

  (a) In the 1930s and early 1940s, many German-speaking scientists developed artificial methods to produce lipids or fats for foods, soaps, fuels, and other products. Glycerin, sterols, fatty acids, and triglycerides were produced from chemical synthesis on an industrial scale and sold for food products and other applications [BIOS 86; BIOS 805; FIAT 213; FIAT 407]. See p. 518.

  (b) Fats were produced and purified from various strains of cultured algae and fungi using biotechnology methods [BIOS 236; BIOS 691; FIAT 371]. In addition to the food applications, this appears to have been the origin of algal and other microbial biofuel technologies. See pp. 2326–2339, 2361–2364, 2430–2444.

  (c) Artificially produced fats were used to make a variety of food products, including cooking oil, cooking fat (shortening), margarine, creamer, salad oil, chocolate [Clarke 1946], synthetic human milk (infant formula) [FIAT 107], etc.

(d) Both the natural science and the practical applications of steroid hormones were developed almost entirely by creators from the greater German-speaking world.[1] See pp. 358–367. The discoveries regarding these hormones had revolutionary, immediate, and long-lasting implications, making possible the creation of pregnancy tests (1927), oral contraceptives (1930), menopause treatments, anabolic steroids, anti-inflammatory steroid drugs, blood pressure medications, therapeutics for high cholesterol, etc.

(e) German-speaking scientists made virtually all of the key discoveries regarding the role of insulin in controlling and preventing diabetes.[2] See pp. 373–374.

(f) During World War II, German-speaking scientists developed freeze-dried human blood for transfusions (pp. 2354–2358).

(g) Also during the war, German-speaking scientists invented and widely used periston synthetic blood plasma (pp. 340–341, 2340–2351, 2418–2429). They created capain synthetic blood plasma too (p. 342).

(h) German-speaking scientists made most of the major discoveries regarding vitamins and their production.[3] See pp. 349–350.

(i) German-speaking scientists developed most of the major preservatives that are still widely used in foods, pharmaceuticals, and biotechnology reagents, such as: (1) Ascorbic acid (vitamin C), which was identified in 1930 by Albert Szent-Györgyi (Hungarian, 1893–1986) and mass-produced via chemical synthesis in 1933 by Tadeusz Reichstein (Polish, educated and worked in Switzerland, 1897–1996). (2) Benzoic acid, which was first analyzed in 1832 by Friedrich Wöhler (German, 1800–1882) and Justus von Liebig (German, 1803–1873). (3) Citric acid, which was first produced from fermentation in fungi in 1890 by Carl Wehmer (German, 1858–1935). (4) Sorbic acid, which was discovered in 1859 by August Wilhelm von Hofmann (German, 1818–1892). (5) Ethylenediaminetetraacetic acid (EDTA), which was synthesized and demonstrated in 1935 by Ferdinand Münz (Austrian, 1888–1969). See pp. 522–523.

(j) German-speaking chemists developed artificial methods of producing caffeine, including from direct chemical synthesis [FIAT 885] and from the conversion of uric acid harvested from snake urine [BIOS 449]. See pp. 514, 2354–2355.

(k) A wide variety of other biomolecules were also produced (for example, see p. 2366).

Thus the available evidence shows that most aspects of biotechnology and molecular biology were developed in the German-speaking world, and that the German-speaking world was the leader in those areas through World War II.

The evidence also shows that knowledge, methods, and materials for biotechnology and molecular biology were transferred to other countries:

- Before the Third Reich, in the form of published and patented information, German-speaking companies (e.g., Röhm and Haas) that transferred technologies to other countries, some scientists (e.g., Carl and Gerty Cori, Chaim Weizmann) who moved to other countries, and scientists from other countries who received part of their education in the German-speaking world.

- During the Third Reich, in the form of published and patented information and also many key scientists (Charlotte Auerbach, Max Bergmann, Ernst Chain, Erwin Chargaff, Max Delbrück, George Gamow, Richard Goldschmidt, Hans Krebs, Max Perutz, Albert Szent-Györgyi, Leo Szilard, etc.) who fled to other countries.

- After the Third Reich, in the form of huge numbers of scientists who moved to other countries, Allied seizures of German and Austrian plants and documents, and Allied reports (BIOS, CIOS, FIAT, etc.) on German and Austrian technologies.

Due to length constraints, this section and Chapter 2 can only briefly mention a limited number of examples. Hopefully other authors will more fully investigate and report the history and contributions of German-speaking scientists to the development of biotechnology and molecular biology.]

H. Benninga. 1990. *A History of Lactic Acid Making: A Chapter in the History of Biotechnology.* Dordrecht: Kluwer.

In 1893 a short communication from the hands of Carl Wehmer appeared about citric acid fermentation in the Bulletin de la Société Chimique de France[...] In the same year he applied for patents in Great Britain (British Patent 5620, granted in 1893) and in Germany (German Patent 72,957, granted in 1894); the "Fabriques de Produits Chimiques de Thann et de Mulhouse" was registered as the owner of both patents.

In the communication to the "Bulletin" Wehmer reported that he had already begun the experiments in 1890, and now was able to produce citric acid on a 10 kg scale. [...]

The first metabolic product obtained by Wehmer was oxalic acid. This acid is present in many plants and in molds as well, which sometimes produce it in appreciable quantities.

The next metabolic acid of importance he discovered was citric acid. Two species of fungi which he denominated *Citromyces*—but today are included in the genus *Penicillium*—were able to produce interesting quantities of citric acid when grown on 10% sugar solutions. Wehmer immediately recognized the practical importance of his findings and applied for patents.

[Wehmer also pioneered the use of cultured fungal cells to produce fumaric acid and possibly other substances as well. See pp. 2316–2319.]

Nº 146. — Note sur la fermentation citrique ;

par M. Charles WEHMER.

Les fermentations acides provoquées par les champignons filamenteux ne sont connues que pour des cas isolés, et quoique le phénomène le mieux étudié de cette catégorie, la formation oxalique, puisse être de quelque intérêt, j'estime que la fermentation citrique en a davantage. En effet, d'après mes expériences et en observant les conditions les plus favorables, il se trouve que l'acide citrique est un produit de sécrétion de quelques moisissures. Ce phénomène est une fermentation dans le genre de celle provoquée par certaines bactéries qui sécrètent les acides acétique et lactique. L'acide citrique, répandu dans le règne végétal, n'a pas encore été observé comme produit de fermentation, et le nombre des acides organiques obtenus de cette façon est restreint. Les observations que j'ai recueillies dans cet ordre d'idées sont en substance les suivantes :

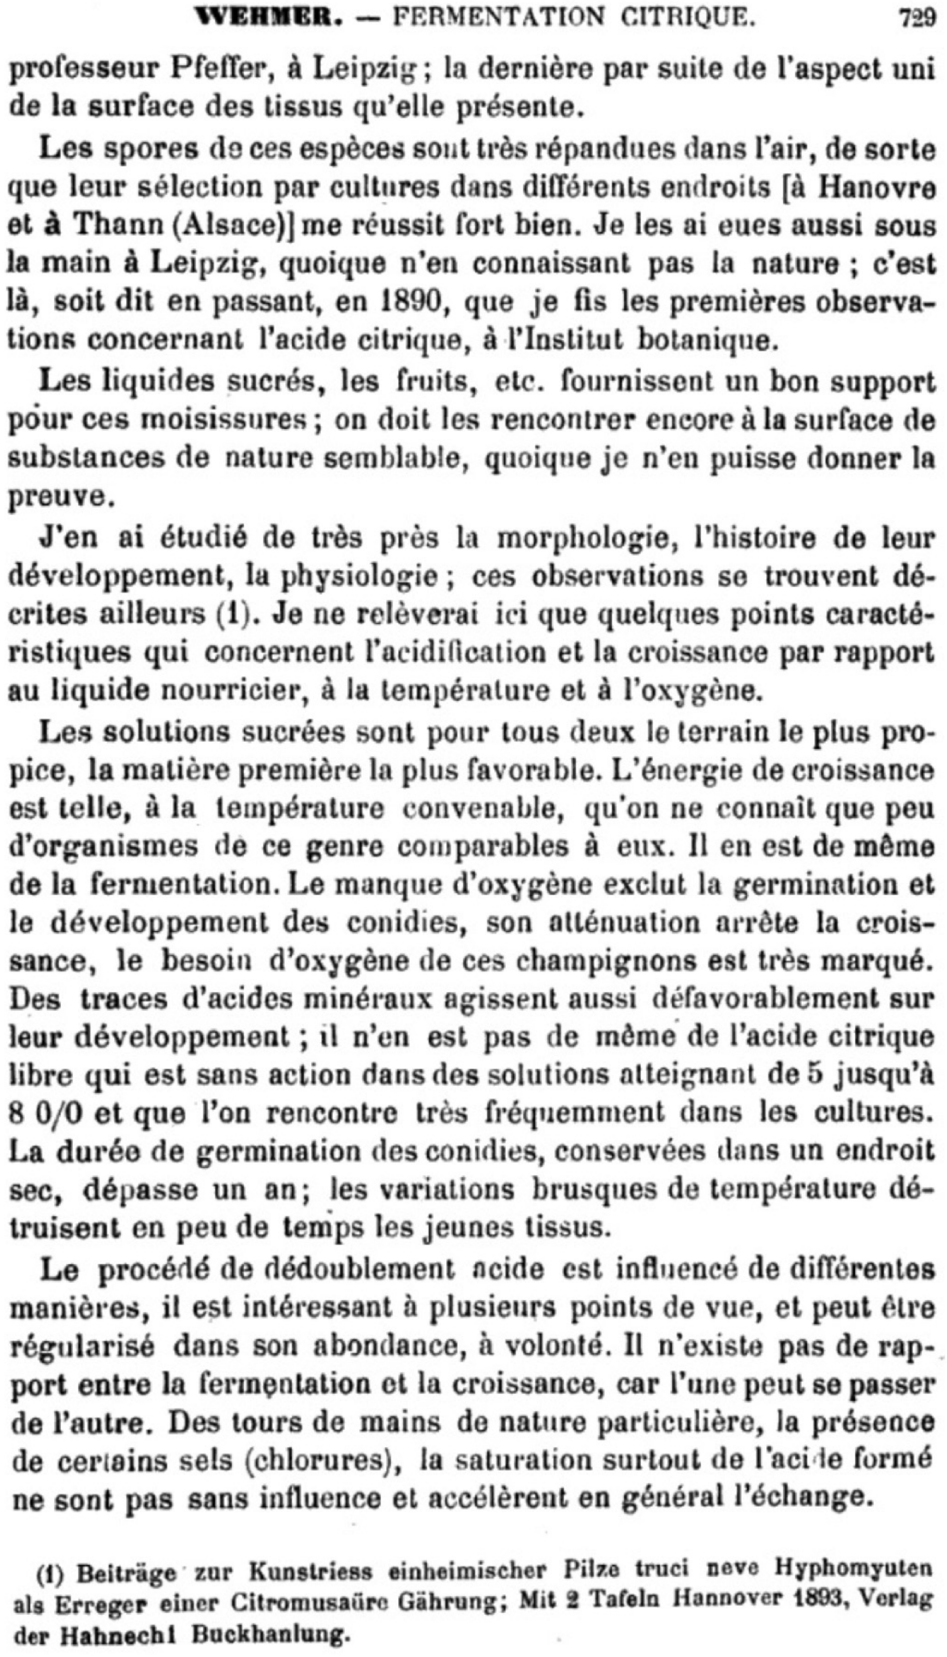
Si l'on abandonne des solutions sucrées, de composition déterminée, à l'action de certains champignons, ceux-ci transforment aussitôt une partie plus ou moins grande de l'hydrate de carbone en un acide qui, chimiquement, est identique à celui que renferme le jus de citron ; on l'obtient aisément sous forme cristalline. La production de cet acide citrique de fermentation n'est pas différente, dans ses traits les plus saillants, de celles par lesquelles on obtient les acides d'un autre genre ; mais les conditions jouent dans le cas particulier un rôle essentiel.

J'ai déterminé, pour le travail qui nous occupe, deux espèces de champignons, et il se trouve que nous sommes en présence d'organismes qui ont échappé à l'observation des savants, en partie, par la raison évidente de la petite dimension de leurs organes reproducteurs et, plus encore, à leur ressemblance macroscopique frappante avec les espèces ordinaires connues.

Ces moisissures apparaissent sur le terrain qui leur convient, sous forme de tissus verts, très compacts, dont on ne distingue de différence avec les espèces du penicillium que grâce au concours du microscope, différence caractérisée, d'ailleurs, par leurs caractères physiologiques. Les différences morphologiques des deux espèces similaires sont difficiles à trouver.

Je propose d'appeler ce genre nouveau de moisissures *citromycètes*, et je désigne ces deux espèces pour les distinguer par C. pfefferianus et C. glaber ; la première en l'honneur de M. le

Figure A.1: Carl Wehmer pioneered the use of cultured fungal cells to produce citric acid and other substances [*Bulletin de la Société Chimique de France* 9:728–730 (1893)].



WEHMER. — FERMENTATION CITRIQUE. 729

professeur Pfeffer, à Leipzig; la dernière par suite de l'aspect uni de la surface des tissus qu'elle présente.

Les spores de ces espèces sont très répandues dans l'air, de sorte que leur sélection par cultures dans différents endroits [à Hanovre et à Thann (Alsace)] me réussit fort bien. Je les ai eues aussi sous la main à Leipzig, quoique n'en connaissant pas la nature; c'est là, soit dit en passant, en 1890, que je fis les premières observations concernant l'acide citrique, à l'Institut botanique.

Les liquides sucrés, les fruits, etc. fournissent un bon support pour ces moisissures; on doit les rencontrer encore à la surface de substances de nature semblable, quoique je n'en puisse donner la preuve.

J'en ai étudié de très près la morphologie, l'histoire de leur développement, la physiologie; ces observations se trouvent décrites ailleurs (1). Je ne relèverai ici que quelques points caractéristiques qui concernent l'acidification et la croissance par rapport au liquide nourricier, à la température et à l'oxygène.

Les solutions sucrées sont pour tous deux le terrain le plus propice, la matière première la plus favorable. L'énergie de croissance est telle, à la température convenable, qu'on ne connaît que peu d'organismes de ce genre comparables à eux. Il en est de même de la fermentation. Le manque d'oxygène exclut la germination et le développement des conidies, son atténuation arrête la croissance, le besoin d'oxygène de ces champignons est très marqué. Des traces d'acides minéraux agissent aussi défavorablement sur leur développement; il n'en est pas de même de l'acide citrique libre qui est sans action dans des solutions atteignant de 5 jusqu'à 8 0/0 et que l'on rencontre très fréquemment dans les cultures. La durée de germination des conidies, conservées dans un endroit sec, dépasse un an; les variations brusques de température détruisent en peu de temps les jeunes tissus.

Le procédé de dédoublement acide est influencé de différentes manières, il est intéressant à plusieurs points de vue, et peut être régularisé dans son abondance, à volonté. Il n'existe pas de rapport entre la fermentation et la croissance, car l'une peut se passer de l'autre. Des tours de mains de nature particulière, la présence de certains sels (chlorures), la saturation surtout de l'acide formé ne sont pas sans influence et accélèrent en général l'échange.

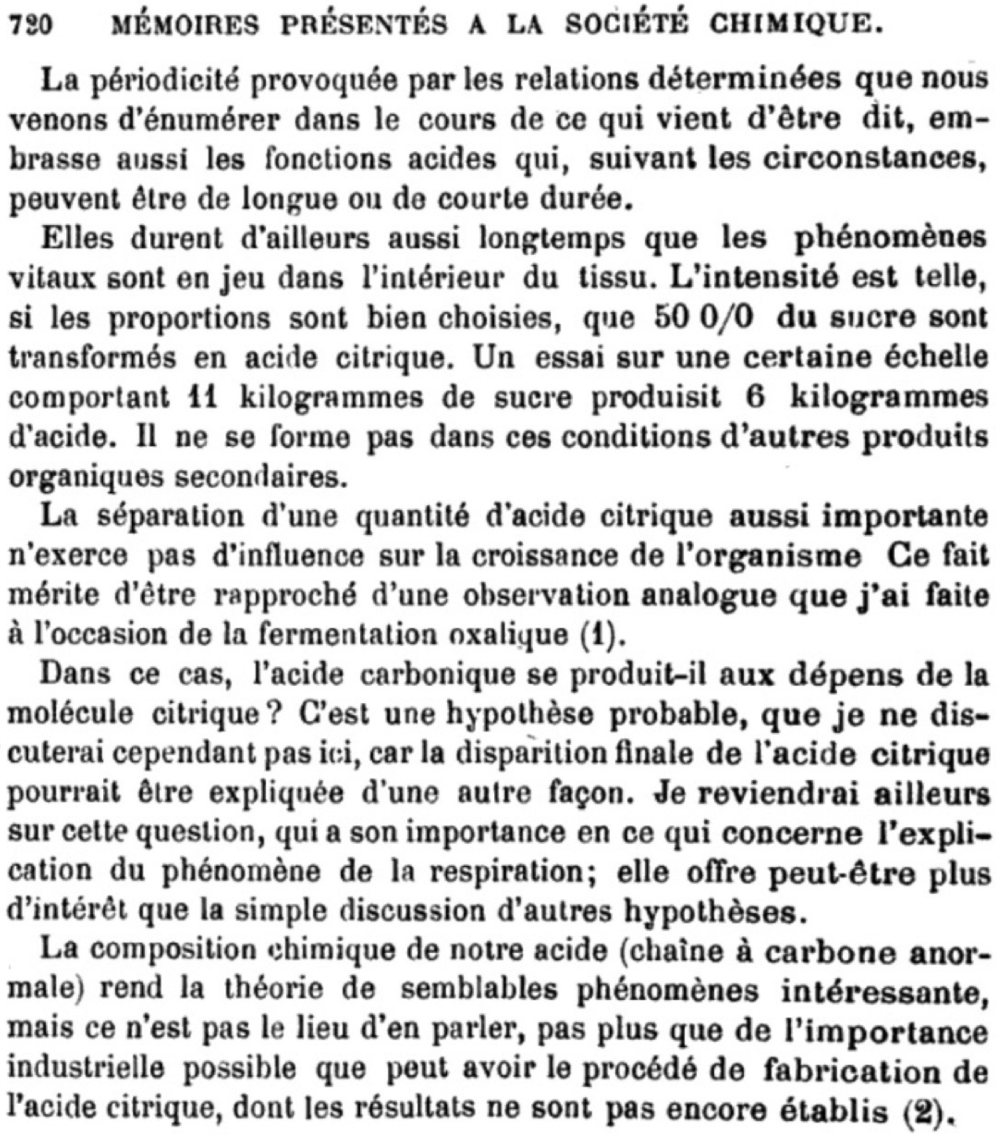
Figure A.2: Carl Wehmer pioneered the use of cultured fungal cells to produce citric acid and other substances [*Bulletin de la Société Chimique de France* 9:728–730 (1893)].



720 MÉMOIRES PRÉSENTÉS A LA SOCIÉTÉ CHIMIQUE.

La périodicité provoquée par les relations déterminées que nous venons d'énumérer dans le cours de ce qui vient d'être dit, embrasse aussi les fonctions acides qui, suivant les circonstances, peuvent être de longue ou de courte durée.

Elles durent d'ailleurs aussi longtemps que les phénomènes vitaux sont en jeu dans l'intérieur du tissu. L'intensité est telle, si les proportions sont bien choisies, que 50 0/0 du sucre sont transformés en acide citrique. Un essai sur une certaine échelle comportant 11 kilogrammes de sucre produisit 6 kilogrammes d'acide. Il ne se forme pas dans ces conditions d'autres produits organiques secondaires.

La séparation d'une quantité d'acide citrique aussi importante n'exerce pas d'influence sur la croissance de l'organisme Ce fait mérite d'être rapproché d'une observation analogue que j'ai faite à l'occasion de la fermentation oxalique (1).

Dans ce cas, l'acide carbonique se produit-il aux dépens de la molécule citrique ? C'est une hypothèse probable, que je ne discuterai cependant pas ici, car la disparition finale de l'acide citrique pourrait être expliquée d'une autre façon. Je reviendrai ailleurs sur cette question, qui a son importance en ce qui concerne l'explication du phénomène de la respiration; elle offre peut-être plus d'intérêt que la simple discussion d'autres hypothèses.

La composition chimique de notre acide (chaîne à carbone anormale) rend la théorie de semblables phénomènes intéressante, mais ce n'est pas le lieu d'en parler, pas plus que de l'importance industrielle possible que peut avoir le procédé de fabrication de l'acide citrique, dont les résultats ne sont pas encore établis (2).

SCHWEIZERISCHE EIDGENOSSENSCHAFT

EIDGEN. AMT FÜR GEISTIGES EIGENTUM

PATENTSCHRIFT

Veröffentlicht am 1. Oktober 1921

Nr. 90955 (Gesuch eingereicht: 22. Juni 1920, 20 Uhr.) **Klasse 36 o**

HAUPTPATENT

Prof. Dr. Carl WEHMER, Hannover (Deutschland).

Verfahren zur Darstellung von Fumarsäure durch Gärung von Zucker.

Die Erfindung betrifft ein Verfahren zur Darstellung von Fumarsäure durch Gärung aus Zucker.

Der Patentinhaber hat gefunden, daß man Zucker, z. B. Maltose, Dextrose und insbesondere Rohrzucker, durch Gärung mittelst des Aspergillus fumaricus bis zu 80 % in Fumarsäure überführen kann. Gleich wie bei anderen Säuregärungen wird die entstehende freie Säure durch zugesetzte Kreide oder andere Neutralisationsmittel abgestumpft. Am Schlusse wird die Fumarsäure durch eine stärkere Säure in Freiheit gesetzt. Der als Aspergillus fumaricus bezeichnete Pilz ist die Laboratoriumsrasse einer von Soja-Bohnen aus Ost-Asien stammenden Schimmelform, die in bekannter Weise gezüchtet wird. Mit Hilfe dieses Pilzes gelingt es zum Beispiel, Rohrzuckerlösungen mit hoher Ausbeute auf Fumarsäure zu vergären, so daß im Mittel 123 % des Zuckers an rohem Calciumfumarat (Maximum bis ca. 160 %) erhalten wurden. Man verfährt also zweckmäßig in der Weise, daß die durch Aufkochen steril gemachten Zuckerlösungen beliebiger Konzentration in geeigneten Gefäßen nach Zugabe eines Neutralisationsmittels, wie Kreide oder dergleichen, mit einer Reinkultur geimpft werden. Bei Verwendung von reinem Zucker sind die üblichen Pilznährstoffe zuzusetzen. Die Pilzentwicklung verläuft unter sonst günstigen Verhältnissen in wenigen Tagen. Die entstehende freie Fumarsäure löst die zugesetzte Kreide unter Gasentwicklung allmählich auf; an ihrer Stelle erscheinen alsdann derbe Krusten von kristallisiertem fumarsaurem Kalk. Nach Trennung von der Flüssigkeit wird aus ihnen durch Schwefelsäure freie kristallisierte Fumarsäure abgeschieden. Die erhältliche Fumarsäure ist in ihren Eigenschaften mit der käuflichen Säure übereinstimmend, sie sublimiert oberhalb 200° unzersetzt in feinen Nädelchen. Der Schmelzpunkt liegt beim Schmelzen in geschlossenen Röhrchen bei ca. 278°.

Beispiel:

Eine Lösung von 100 Teilen Zucker in 1 Liter Wasser wird nach Zusatz von 25 gr Kreide und den üblichen Pilznährstoffen mit einer Kultur des Fumarsäurepilzes geimpft. In 2—3 Wochen langer Gärung bei 20° scheiden sich rund 120 gr Calciumfumarat ab, aus dem durch Schwefelsäure die Fumarsäure freigemacht und durch Lösen in Alkohol und Filtrieren der Lösung vom Gips getrennt wird. Man kann auch das Kalksalz zunächst in das Bleisalz überführen und dieses durch Schwefelwasserstoff zerlegen.

PATENTANSPRUCH:

Verfahren zur Darstellung von Fumarsäure durch Gärung aus Zucker, dadurch gekennzeichnet, daß man eine Zuckerlösung mittelst Aspergillus fumaricus vergärt, die dabei entstehende freie Fumarsäure durch zugesetzte Neutralisationsmittel bindet und hierauf durch eine stärkere Säure in Freiheit setzt.

platte auf, mit der trichterförmigen Erweiterung nach oben, so wird die axiale Bohrung derselben unten durch die Grundplatte abgeschlossen. Durch Einbringen der Substanz in das Bohrloch von der trichterförmigen Erweiterung aus und einmaliges Nachstopfen mit dem in die Bohrung genau passenden Zapfen des mit Griff ausgestatteten Stopfers gelingt es, durch verhältnismäßig leichten Handdruck eine fest zusammenhaltende Pastille in den Raum zu pressen. Um sie aus der Pastillenkammer zu entfernen (Fig. 35c), schiebt man einen 8 mm breiten Metallring zwischen die Grundplatte und die die Pastille in ihrem Innern tragende Platte, stößt die Pastille mit einem kurzen Schlag auf den Stopfer durch, worauf sie innerhalb des Ringes auf die Grundplatte zu liegen kommt.

Fig. 35. a) Pastillenpresse, Ansicht, b) Durchschnitt, c) Auspressen der fertigen Pastille. ($^1/_2$ natürl. Größe.)

Erfahrungsgemäß empfiehlt es sich, in dieser Weise Pastillen im Gewichte von 7, höchstens 10 mg anzufertigen. Sie werden in Substanzröhrchen, wie sie bei der Stickstoffbestimmung Verwendung finden, mit einer Genauigkeit von nur 0,01 mg gewogen und die erste sofort in den Apparat eingetragen, sobald der Siedepunkt konstant geworden ist. Nach erfolgter Lösung steigt der Siede-

BIOS 219. ***Work on Synthesis and Production of Drugs 3065 (2:2^1-Dihydroxy-5:5^1-Dibrome Benzil) and 3214 (2:2^1-Dihydroxy-3:3^1-5:5^1-Tetrachlor Benzil).***

The M.L.D. of 3065 is one gram per kilogram which is almost the same as sulphapyridine.

[Richard Kuhn] stated that 3065 is the first compound found to be effective against Rickettsia virus and Influenza virus strain A. These experiments have been carried out at Marburg. In a typical experiment on mice infected with Influenza virus strain A, all the treated animals survived whereas all the control group were dead within 6–7 days.

A number of cases of Gonorrhea had responded to treatment with 3065 after being unsuccessfully treated with the sulphonamides.

The main clinical trials on 3065 have been on amputations, thoracoplastic work, and ruptured appendices. Summaries of some of these clinical trials are given in Appendix II.

Prof. Kuhn stated that the drug was first prepared at the end of 1943, and asked about cost he was of the opinion that it would be more expensive than the sulpha drugs.

After the discussion on the drug work inspection was made of the laboratories and the following three items of general interest noted.

1. Prof. Zimmerman, who was working at the I.G. Farben in Ludwigshafen, developed during the war an automatic micro-analysis apparatus which is capable of carrying out 16 micro-analyses per day. Details of this apparatus have not been published and Prof. Kuhn was of the opinion that it would be rather difficult to obtain the essential details of construction.

2. The attack on potatoes by the Colorado Beetle has been a severe problem during the war. The work carried out under the supervision of Kuhn has revealed that an alkaloid can be extracted from the leaves of resistant types of potatoes, bred at an agricultural station near Heidelberg, but there has been no evidence that this substance occurs in plants that are attacked.

3. Kapsenberg Caps. The caps have been developed and used as an alternative to cotton wool plugs in bacteriological tubes and according to Kuhn have entirely supplanted the use of cotton wool at the K.W.I. The caps are made from aluminium and the attached sketch gives some idea of their construction.

   [...] According to Ambros he was simply making 3065 as a personal favor for Kuhn since they are close friends. [...]

   In vitro experiments with 3065 and Burroughs-Wellcome penicillin which had been captured from the British Army showed that 3065 was 300 times more effective against staphylococcus aureus. Ambros pointed out, however, that they did not know the history of [the] penicillin so that it may have undergone some deterioration before they got it. Also the difference in solubility between the two compounds made comparison difficult. A clinical test carried out on a leg amputation wound has shown that 3065 was five to six times more effective than Marfinil.

   Naturally he was not able to give any figures on cost since the material had only been made in the laboratory, but he seemed to think that it would be produced for something like 10–20 Marks per kilogram.

BIOS 236. ***Developments in Pure and Applied Microbiology (American, British and French Zones) During World War II.***

SECTION "A"

DEVELOPMENTS IN PURE AND APPLIED MICROBIOLOGY IN GERMANY (AMERICAN, FRENCH & BRITISH ZONES) DURING WORLD WAR II

[...T]he study of industrial microbiology is really in its infancy, and developments are to a large extent dependent on the outcome of fundamental investigations in research laboratories. A considerable part of the work of the [BIOS] team was therefore concerned with the review of relevant investigations in agricultural experiment stations, universities and other research institutions. [...]

Prof. [F.] Rindel's interests cover a wide field. His earlier work was in the field of pure organic chemistry, and he had within recent years revised Richter's textbook on Organic Chemistry. From a study of the chemistry of various microbiological products, his interests had extended to many nutritional problems. A list of his publications during the war period is given below (5 to 10), but his contacts with microbiological research extended beyond the subjects of these papers.

On the subject of food yeast and other protein preparations of microbiological origin he gave the following information and opinions:

(a) Lactose-fermenting strains of yeast had been isolated which yielded 52 Kg of protein per 100 Kg lactose. These were of no use for bakery purposes, but other lactose-fermenting yeasts had been isolated which would give good gas-production when whey is incorporated in bread dough.

(b) Yeast protein is lacking in cysteine and when fed alone to rats, causes liver damage. The authority for this statement was given as Dr. Fink, who had been associated with the development of the fermentation of wood sugar by Torulopsis utilis and was now stated to be with the Irex Company at Fulbach. Later a similar view was expressed by Prof Lembke of Kiel (see report on protein production by micro-organisms issued separately).

(c) Food yeast grown on waste sulphite liquor from wood pulp had frequently been found to contain lead to the extent of 70 to 80 parts per million (determined by dithizone).

(d) Organisms other than Torulopsis utilis had been used to produce protein for food purposes, e.g. Oidium lactis at a factory at Lenzing, Austria (reference to our visit to this factory is included in our separate report), and Aspergillus sp. at a factory at Traunstein, between Salzburg and Munch. (It was not possible to devote time to locating this factory). Prof Reindel was dubious about using such protein preparations as food until it had been established that they are free from anti-biotic substances. [...]

From the industrial standpoint, the work of most significance appeared to be that on fat production by micro-organisms. An undeveloped observation was that yeasts of the genus Nectaromyces give high fat yields (10 to 15 g per 100 g. sugar utilized) when cultivated by the aeration procedure used for Torulopsis utilis and other yeasts used for food purposes or bread fermentation.

Prof Rippel had recently completed an advanced textbook on the physiology and morphology of micro-organisms which was to have been published by J. Springer of Berlin. [...]

Prof Dr. S. Strugger, however, had been transferred to this institute from the Botanical Institute of the University of Jena, where his work had been financed by the firm Carl Zeiss. He is a cytologist and one of the editors of the journal "Protoplasma". During the war he had been developing the technique of fluorescence microscopy, using Zeiss apparatus with quartz lenses [...], and had also studied methods of vital staining of bacterial cells and spermatozoa using acridine-orange[...] The technique was demonstrated to us and appear to be rapid and reliable for application to the control of certain industrial fermentations. [...]

SECTION "B"

PRODUCTION OF PROTEIN BY MICROBIOLOGICAL METHODS

[...] During the war the German food economy was particularly short of proteins and fat. An intensive effort was therefore made to overcome part of this deficiency through the production of micro-organisms which could be grown on carbohydrates present in whey or the waste liquors from pulp mills. In addition plants were erected to hydrolyse wood cellulose to sugars for this purpose and the necessary nitrogen was supplied in the form of inorganic ammonium salts. This report summarises the processes used in three industrial plants for the production of proteins and does not claim to be comprehensive. The first section deals with production of wood sugars by the Bergius process using concentrated hydrochloric acid. Following this is an account of the Scholler process in which dilute sulphuric acid is used to saccharify wood. On the medium obtained Torula utilis was grown to produce proteins. The third section describes a process used in a wood pulp plant whereby Oidium lactis was grown on waste sulphite liquor for the same purpose. The use of this product as human food had not met with approval and, although on industrial scale, the process was really still experimental.

The final report deals with some of the laboratory research leading up to the cultivation of moulds for their nutritive qualities. [...]

A short interview with Dr. [Andreas] Lembke in the Sanatorium indicated that he had carried on considerable research work on the question of cultivating mould for the production of protein. He stated that during the first World War, his predecessor, Professor Henneberg had begun the cultivation of yeasts for use in protein supplement while working in the Garungewerbe Institute of Berlin. He had also discovered that urea could be fed to cows with beneficial results as a source of nitrogen. After Prof. Henneberg's death in 1936 his work was continued by Prof. Lembke in Kiel.

Prof. Lembke's interest in this work centred around the nature of the amino acids produced by yeasts and moulds. He cultivated many different strains of moulds but found that only a few races were rich in cysteine, methionine and glutathione. Since most yeasts being grown for protein production were very low in cysteine he was anxious to select other organisms which were rich in this particular amino acid. He claims to have had success in obtaining cultures of several moulds which met these requirements.

Strains of Fusarium, Candida, Oidium, Endomyces and Rhizopus were cultured and both wet and dry powdered preparations were made for use in feeding experiments. Some of these products were smoked like bacon or sausages and he said they were quite edible. Being a doctor of medicine as well as a microbiologist, he conducted nutritional studies and claimed that feeding up to 60 grams per day for over 6 months had been beneficial. He stated that the general health of the group of people fed on these proteins was better than the controls.

In feeding experiments he said that it was very important that the moulds should be heated or autolysed before eating them, otherwise they caused diarrhoea.

Of the different moulds used in this work Prof. Lembke thought Fusarium was probably the most satisfactory. He said the East Munich Dairy Station was growing Fusarium on whey. It was also quite satisfactory when grown on waste sulphite liquor. [...]

SECTION “C”

PRODUCTION OF FATS BY MICROBIOLOGICAL METHODS

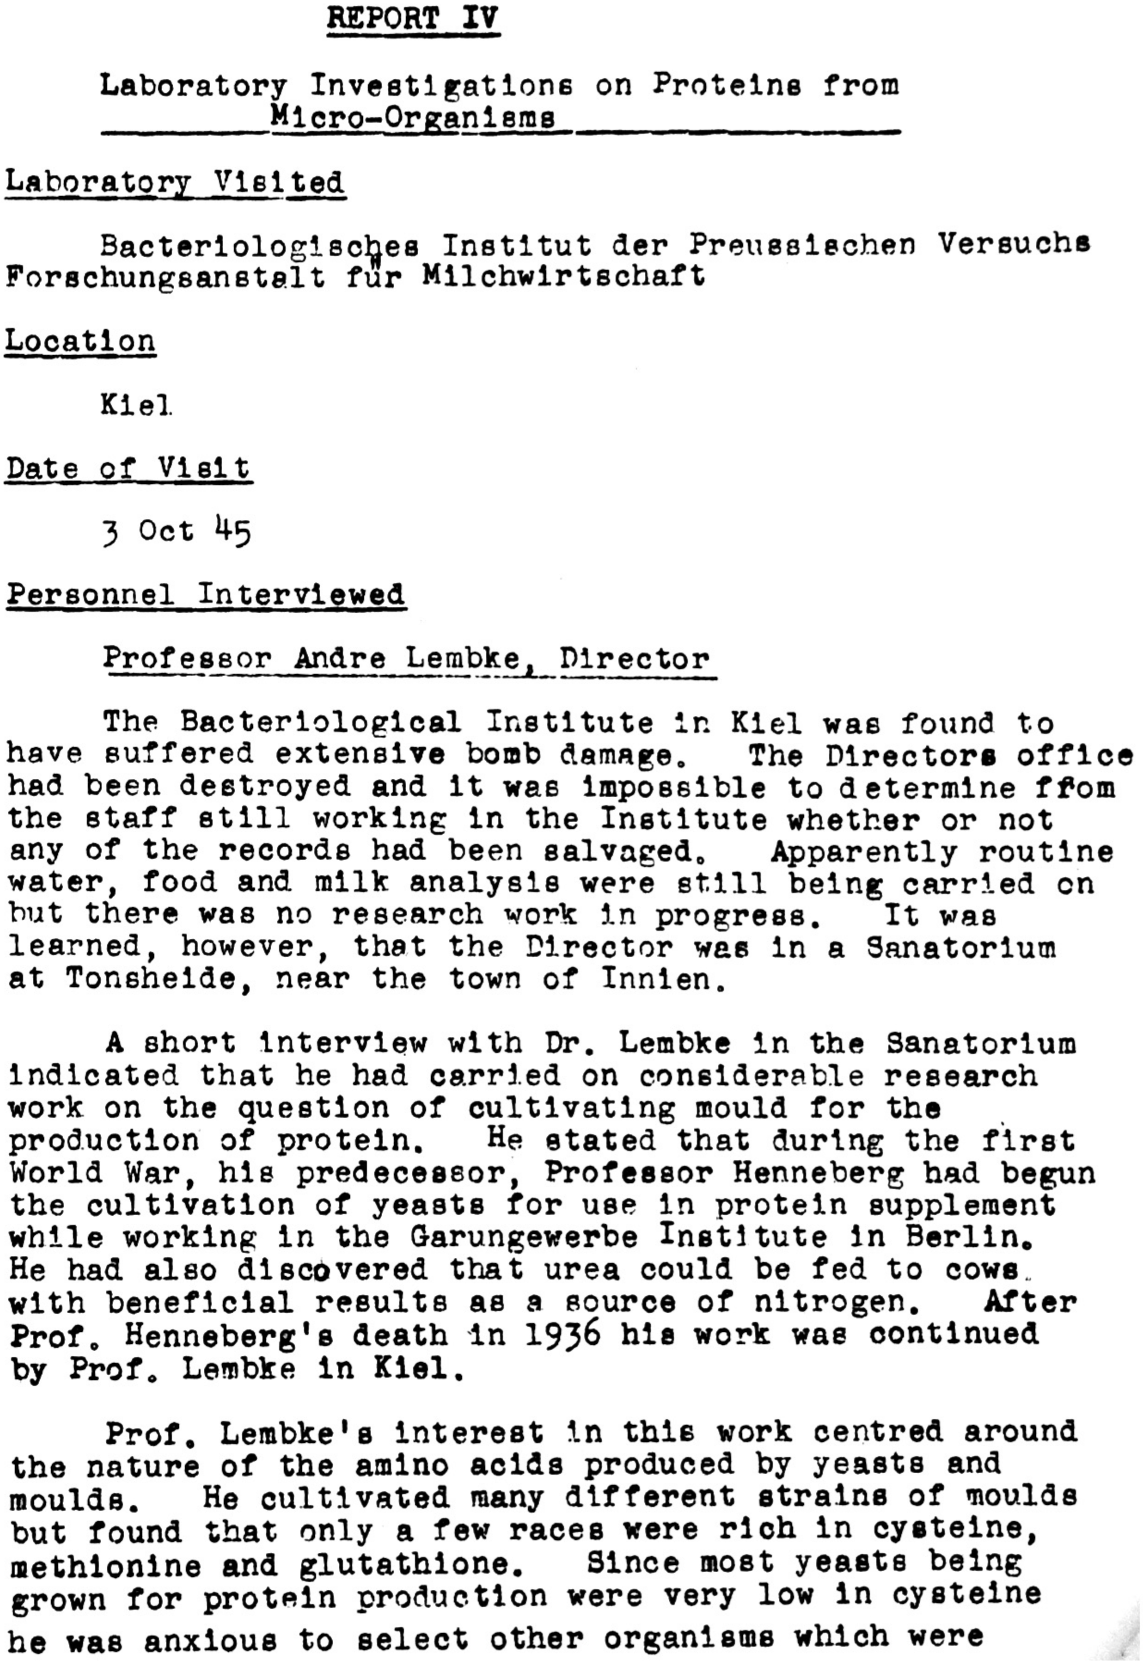
The process showed some novel feature with regard to the cultivation of a mould [Oidium lactis] for high fat production and with regard to the combination of different types of waste material used.

SECTION “D”

ORGANIC ACID MANUFACTURE BY MICROBIOLOGICAL METHODS IN GERMANY

[...] This firm was equipped for preparing lactic, gluconic and citric acids by microbiological methods, but was not producing these at the time of the inspection, owing to shortage of fuel. The plant had in each case been installed prior to the war, that for citric acid immediately prior to the war. [...]

The firm Boehringer was established in Wurtemberg over a century ago and was concerned originally with the manufacture of tartaric acid and tartrates from wine byproducts. A branch was established in Oberingelheim in 1885 to manufacture lactic acid by a fermentating process and the firm claims to be a pioneer in this field. Subsequently other fermentation processes were introduced, and a large section of the firm is now concerned with the manufacture of pharmaceutical preparations by chemical methods. This last aspect of the firm’s activities was outside the scope of our investigations.



REPORT IV

Laboratory Investigations on Proteins from Micro-Organisms

Laboratory Visited

Bacteriologisches Institut der Preussischen Versuchs Forschungsanstalt für Milchwirtschaft

Location

Kiel.

Date of Visit

3 Oct 45

Personnel Interviewed

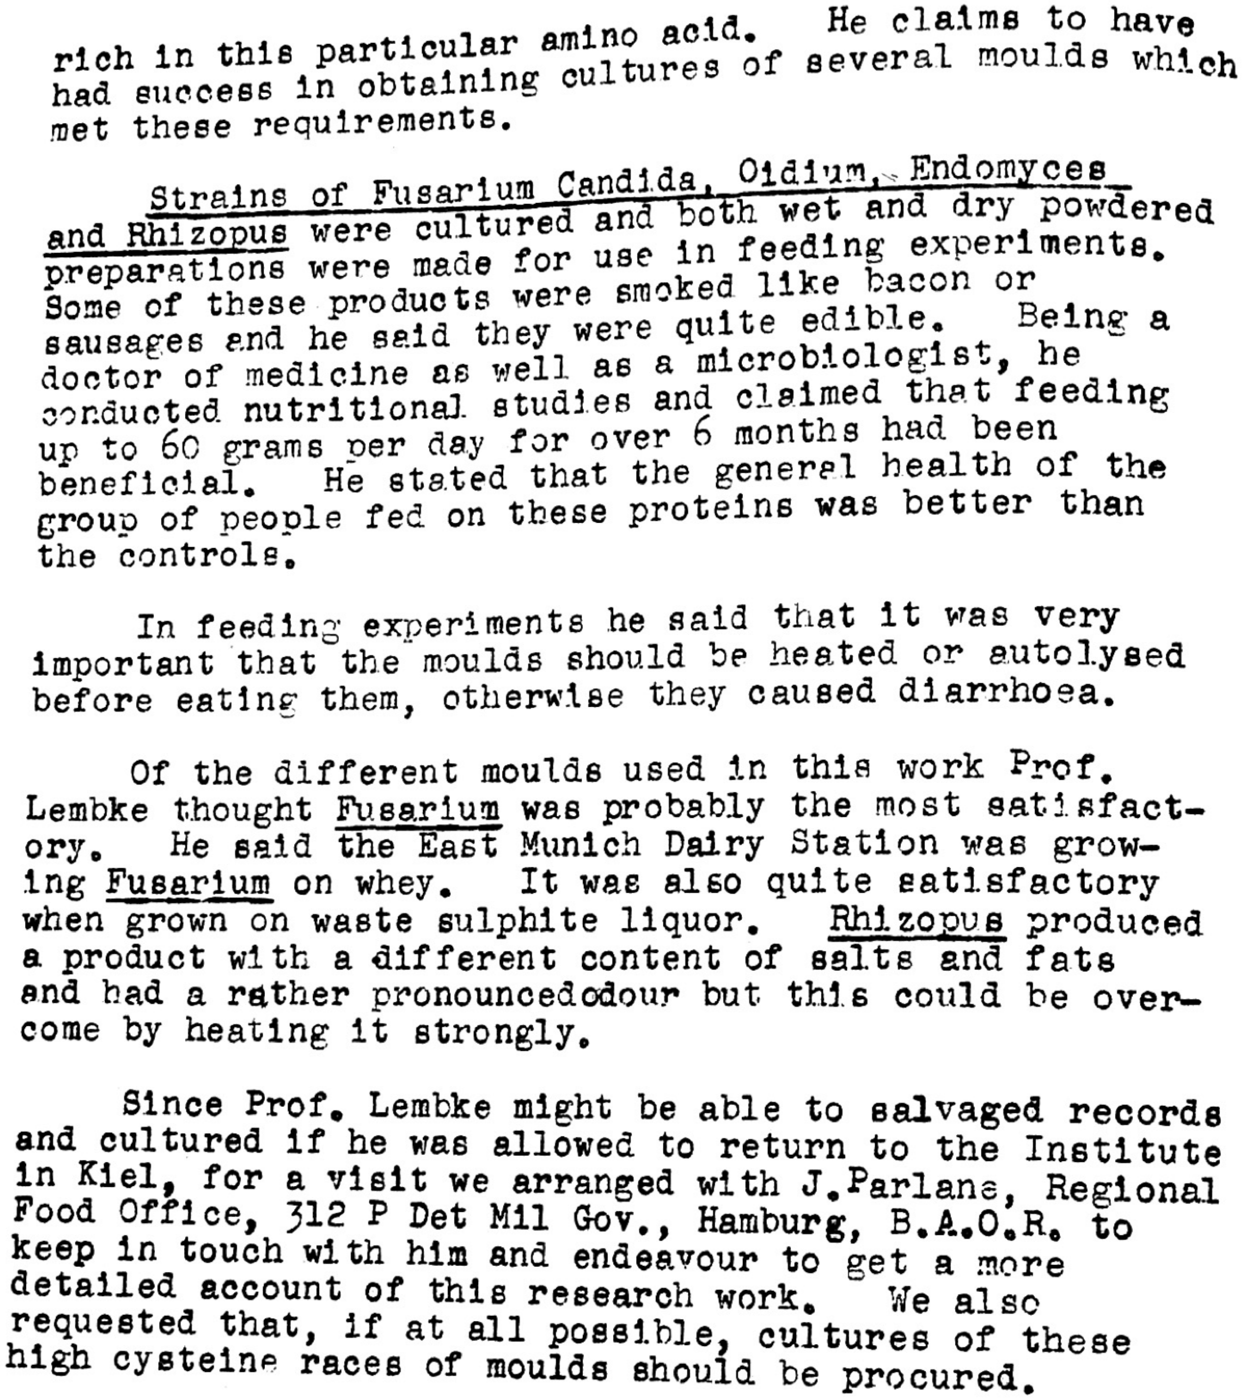
Professor Andre Lembke, Director

The Bacteriological Institute in Kiel was found to have suffered extensive bomb damage. The Directors office had been destroyed and it was impossible to determine ffom the staff still working in the Institute whether or not any of the records had been salvaged. Apparently routine water, food and milk analysis were still being carried on but there was no research work in progress. It was learned, however, that the Director was in a Sanatorium at Tonsheide, near the town of Innien.

A short interview with Dr. Lembke in the Sanatorium indicated that he had carried on considerable research work on the question of cultivating mould for the production of protein. He stated that during the first World War, his predecessor, Professor Henneberg had begun the cultivation of yeasts for use in protein supplement while working in the Garungewerbe Institute in Berlin. He had also discovered that urea could be fed to cows with beneficial results as a source of nitrogen. After Prof. Henneberg's death in 1936 his work was continued by Prof. Lembke in Kiel.

Prof. Lembke's interest in this work centred around the nature of the amino acids produced by yeasts and moulds. He cultivated many different strains of moulds but found that only a few races were rich in cysteine, methionine and glutathione. Since most yeasts being grown for protein production were very low in cysteine he was anxious to select other organisms which were

Figure A.10: Biotechnology methods for producing and purifying edible protein from cultured yeast [BIOS 236].



rich in this particular amino acid. He claims to have had success in obtaining cultures of several moulds which met these requirements.

Strains of Fusarium Candida, Oidium, Endomyces and Rhizopus were cultured and both wet and dry powdered preparations were made for use in feeding experiments. Some of these products were smoked like bacon or sausages and he said they were quite edible. Being a doctor of medicine as well as a microbiologist, he conducted nutritional studies and claimed that feeding up to 60 grams per day for over 6 months had been beneficial. He stated that the general health of the group of people fed on these proteins was better than the controls.

In feeding experiments he said that it was very important that the moulds should be heated or autolysed before eating them, otherwise they caused diarrhoea.

Of the different moulds used in this work Prof. Lembke thought Fusarium was probably the most satisfactory. He said the East Munich Dairy Station was growing Fusarium on whey. It was also quite satisfactory when grown on waste sulphite liquor. Rhizopus produced a product with a different content of salts and fats and had a rather pronounced odour but this could be overcome by heating it strongly.

Since Prof. Lembke might be able to salvaged records and cultured if he was allowed to return to the Institute in Kiel, for a visit we arranged with J.Parlane, Regional Food Office, 312 P Det Mil Gov., Hamburg, B.A.O.R. to keep in touch with him and endeavour to get a more detailed account of this research work. We also requested that, if at all possible, cultures of these high cysteine races of moulds should be procured.

Production of Fat from Oidium Lactis

Plant Visited

Biologisch Chemisch Gesellschaft m.b.H. C22/2056

Location

Bad Tölz

Date of Visit

11 and 15 Sep 45

Object of Visit

To obtain information on the laboratory and pilot plant scale production of fat from OIDIUM LACTIS

Summary

The process showed some novel features with regard to the cultivation of a mould for high fat production and with regard to the combination of different types of waste material.used.

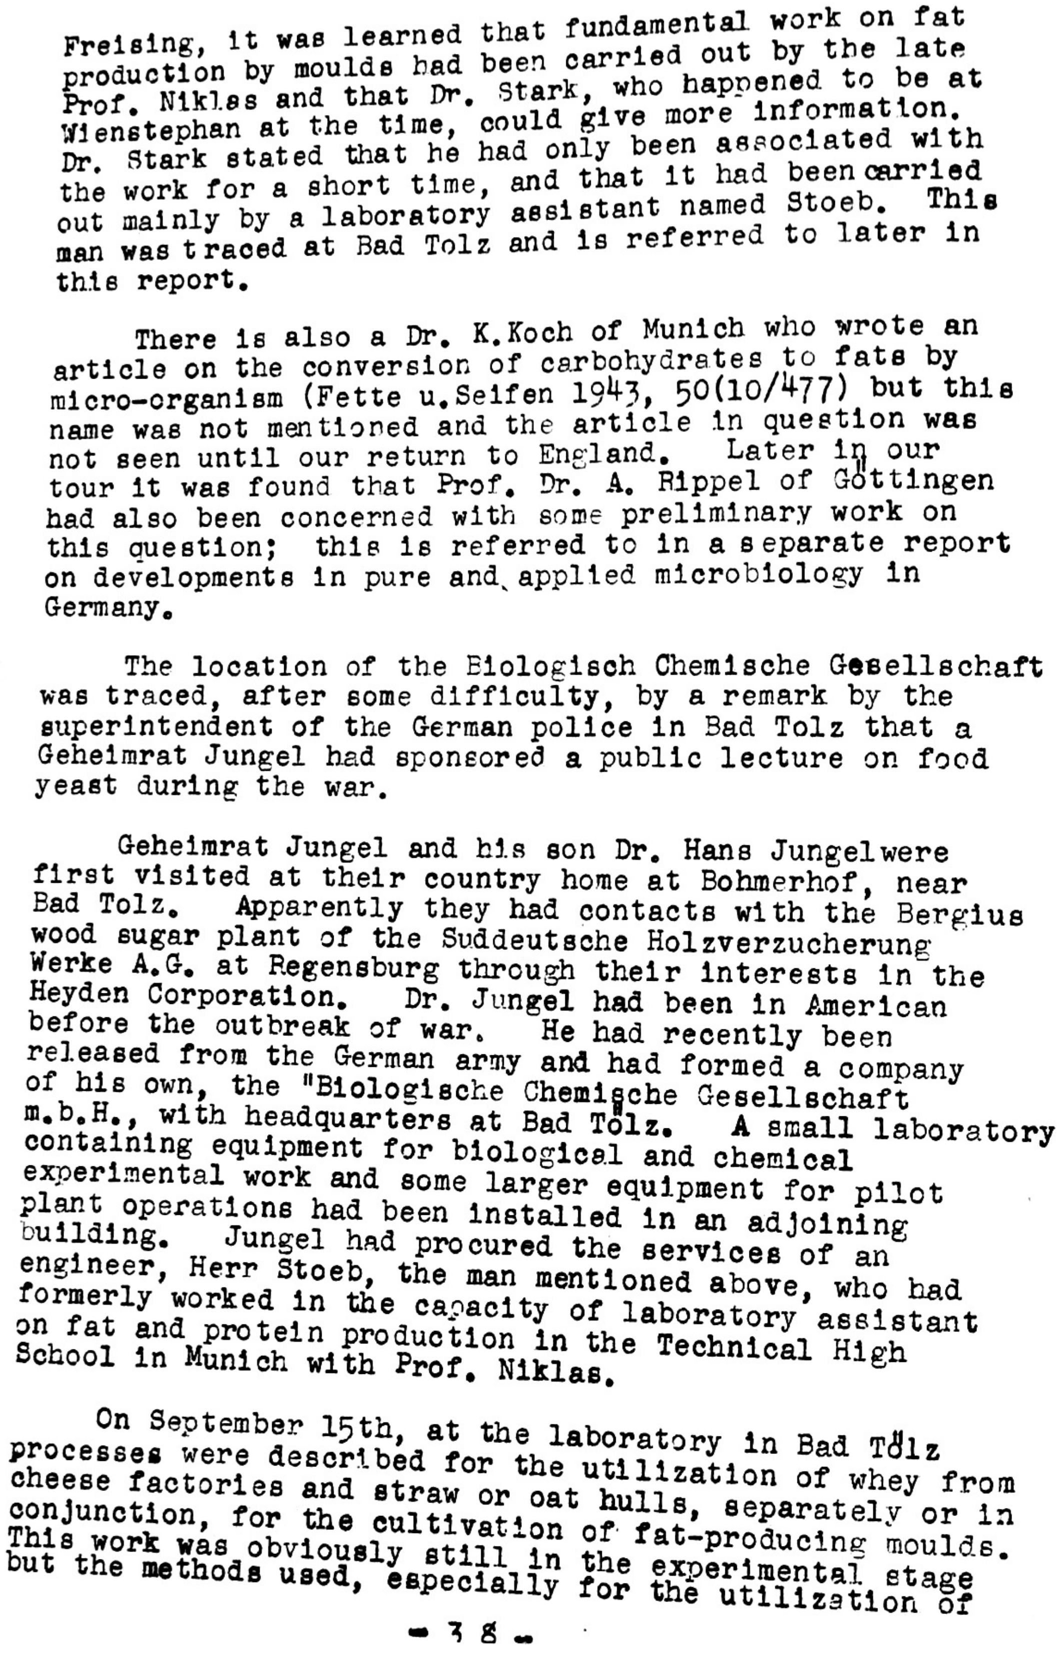
Personnel Interviewed

Geheimrat Jungel - Director
Dr. H. Jungel - Director
Herr Stoeb - Unqualified Chemical Engineer

General

From information received from Prof. Fromel and Prof. Schropp at Weinstephan Agricultural College,

Figure A.12: Biotechnology methods for producing and purifying lipids from cultured yeast [BIOS 236].



Freising, it was learned that fundamental work on fat production by moulds had been carried out by the late Prof. Niklas and that Dr. Stark, who happened to be at Wienstephan at the time, could give more information. Dr. Stark stated that he had only been associated with the work for a short time, and that it had been carried out mainly by a laboratory assistant named Stoeb. This man was traced at Bad Tolz and is referred to later in this report.

There is also a Dr. K.Koch of Munich who wrote an article on the conversion of carbohydrates to fats by micro-organism (Fette u.Seifen 1943, 50(10/477) but this name was not mentioned and the article in question was not seen until our return to England. Later in our tour it was found that Prof. Dr. A. Rippel of Göttingen had also been concerned with some preliminary work on this question; this is referred to in a separate report on developments in pure and applied microbiology in Germany.

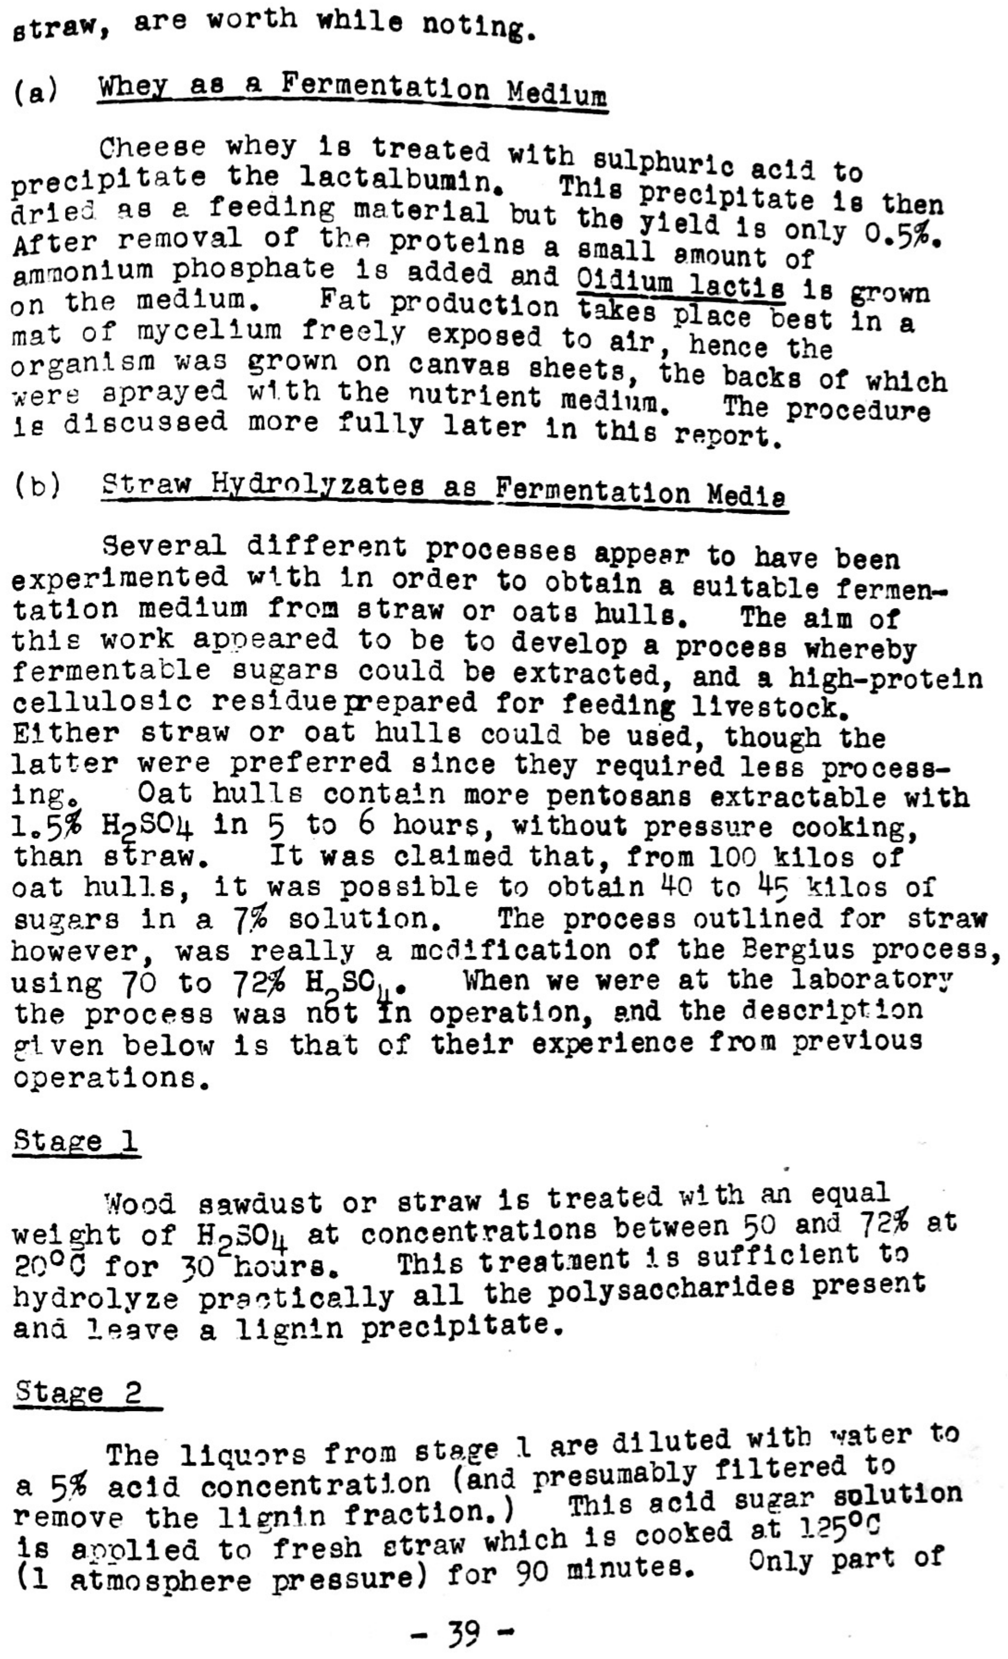
The location of the Biologisch Chemische Gesellschaft was traced, after some difficulty, by a remark by the superintendent of the German police in Bad Tolz that a Geheimrat Jungel had sponsored a public lecture on food yeast during the war.

Geheimrat Jungel and his son Dr. Hans Jungel were first visited at their country home at Bohmerhof, near Bad Tolz. Apparently they had contacts with the Bergius wood sugar plant of the Suddeutsche Holzverzucherung Werke A.G. at Regensburg through their interests in the Heyden Corporation. Dr. Jungel had been in American before the outbreak of war. He had recently been released from the German army and had formed a company of his own, the "Biologische Chemische Gesellschaft m.b.H., with headquarters at Bad Tölz. A small laboratory containing equipment for biological and chemical experimental work and some larger equipment for pilot plant operations had been installed in an adjoining building. Jungel had procured the services of an engineer, Herr Stoeb, the man mentioned above, who had formerly worked in the capacity of laboratory assistant on fat and protein production in the Technical High School in Munich with Prof. Niklas.

On September 15th, at the laboratory in Bad Tölz processes were described for the utilization of whey from cheese factories and straw or oat hulls, separately or in conjunction, for the cultivation of fat-producing moulds. This work was obviously still in the experimental stage but the methods used, especially for the utilization of

- 38 -

Figure A.13: Biotechnology methods for producing and purifying lipids from cultured yeast [BIOS 236].



straw, are worth while noting.

(a) Whey as a Fermentation Medium

Cheese whey is treated with sulphuric acid to precipitate the lactalbumin. This precipitate is then dried as a feeding material but the yield is only 0.5%. After removal of the proteins a small amount of ammonium phosphate is added and Oidium lactis is grown on the medium. Fat production takes place best in a mat of mycelium freely exposed to air, hence the organism was grown on canvas sheets, the backs of which were sprayed with the nutrient medium. The procedure is discussed more fully later in this report.

(b) Straw Hydrolyzates as Fermentation Media

Several different processes appear to have been experimented with in order to obtain a suitable fermentation medium from straw or oats hulls. The aim of this work appeared to be to develop a process whereby fermentable sugars could be extracted, and a high-protein cellulosic residue prepared for feeding livestock. Either straw or oat hulls could be used, though the latter were preferred since they required less processing. Oat hulls contain more pentosans extractable with 1.5% H_2SO_4 in 5 to 6 hours, without pressure cooking, than straw. It was claimed that, from 100 kilos of oat hulls, it was possible to obtain 40 to 45 kilos of sugars in a 7% solution. The process outlined for straw however, was really a modification of the Bergius process, using 70 to 72% H_2SO_4. When we were at the laboratory the process was not in operation, and the description given below is that of their experience from previous operations.

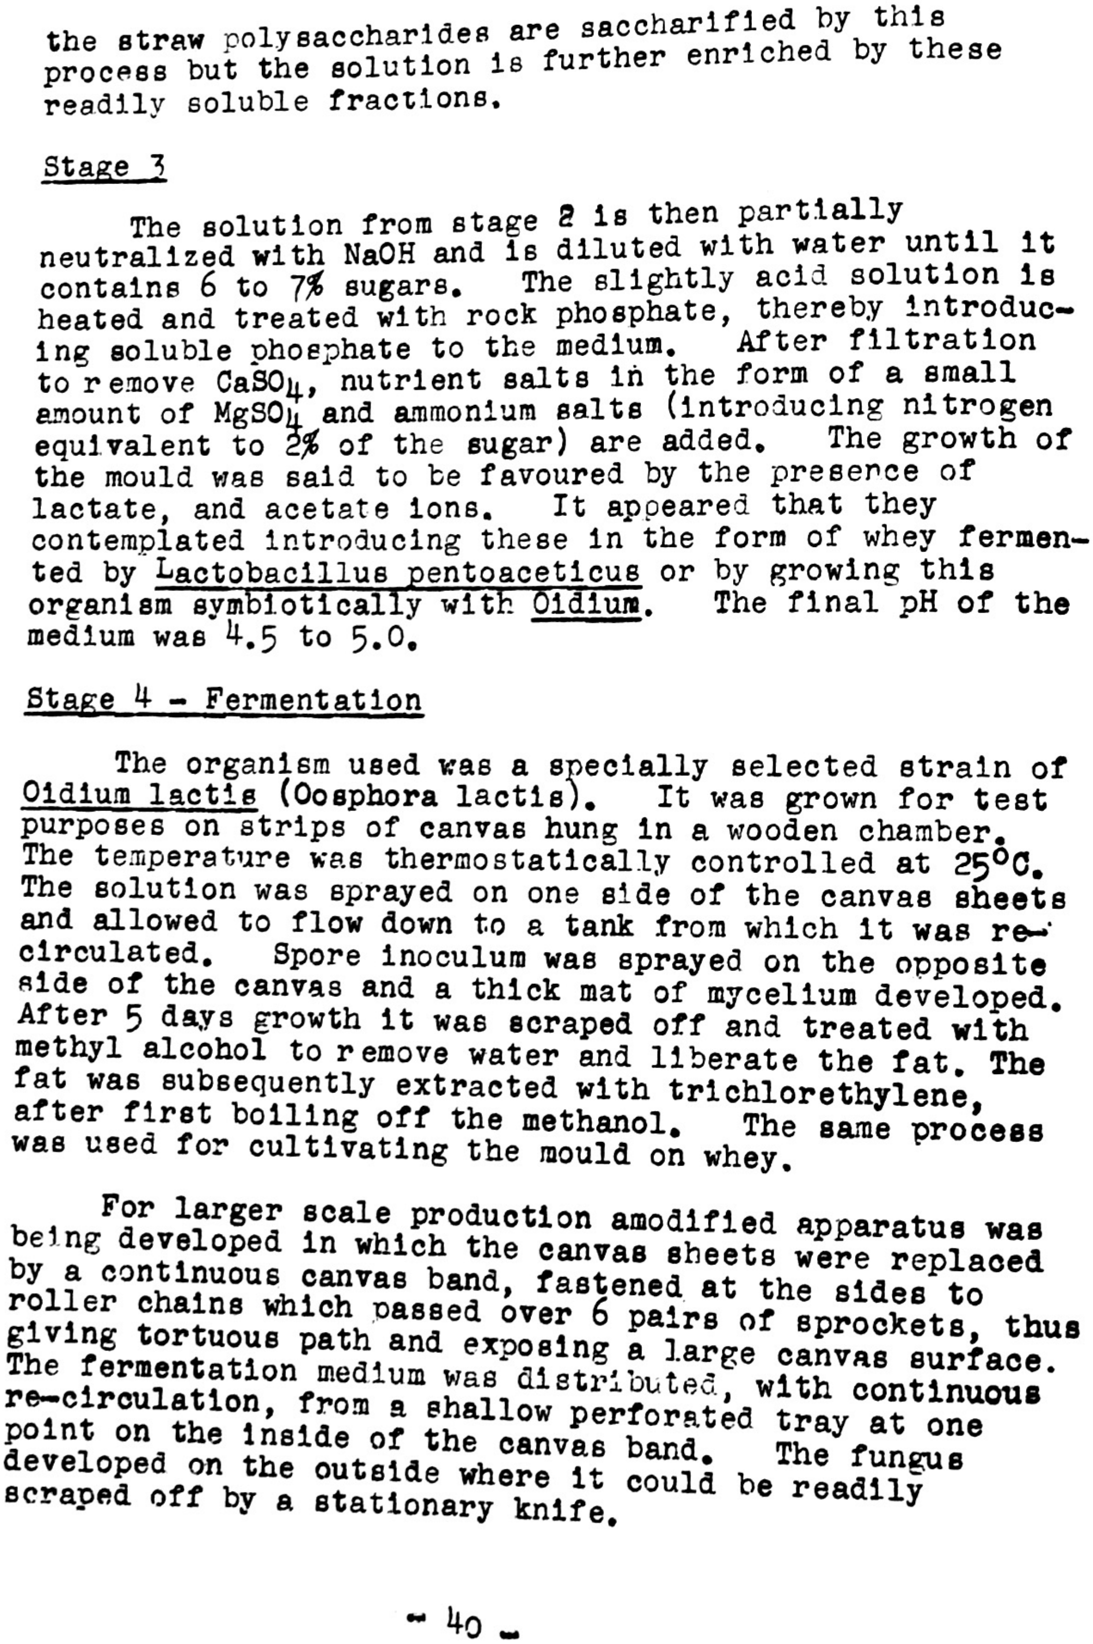
Stage 1

Wood sawdust or straw is treated with an equal weight of H_2SO_4 at concentrations between 50 and 72% at 20°C for 30 hours. This treatment is sufficient to hydrolyze practically all the polysaccharides present and leave a lignin precipitate.

Stage 2

The liquors from stage 1 are diluted with water to a 5% acid concentration (and presumably filtered to remove the lignin fraction.) This acid sugar solution is applied to fresh straw which is cooked at 125°C (1 atmosphere pressure) for 90 minutes. Only part of

Figure A.14: Biotechnology methods for producing and purifying lipids from cultured yeast [BIOS 236].



the straw polysaccharides are saccharified by this process but the solution is further enriched by these readily soluble fractions.

Stage 3

The solution from stage 2 is then partially neutralized with NaOH and is diluted with water until it contains 6 to 7% sugars. The slightly acid solution is heated and treated with rock phosphate, thereby introducing soluble phosphate to the medium. After filtration to remove $CaSO_4$, nutrient salts in the form of a small amount of $MgSO_4$ and ammonium salts (introducing nitrogen equivalent to 2% of the sugar) are added. The growth of the mould was said to be favoured by the presence of lactate, and acetate ions. It appeared that they contemplated introducing these in the form of whey fermented by *Lactobacillus pentoaceticus* or by growing this organism symbiotically with *Oidium*. The final pH of the medium was 4.5 to 5.0.

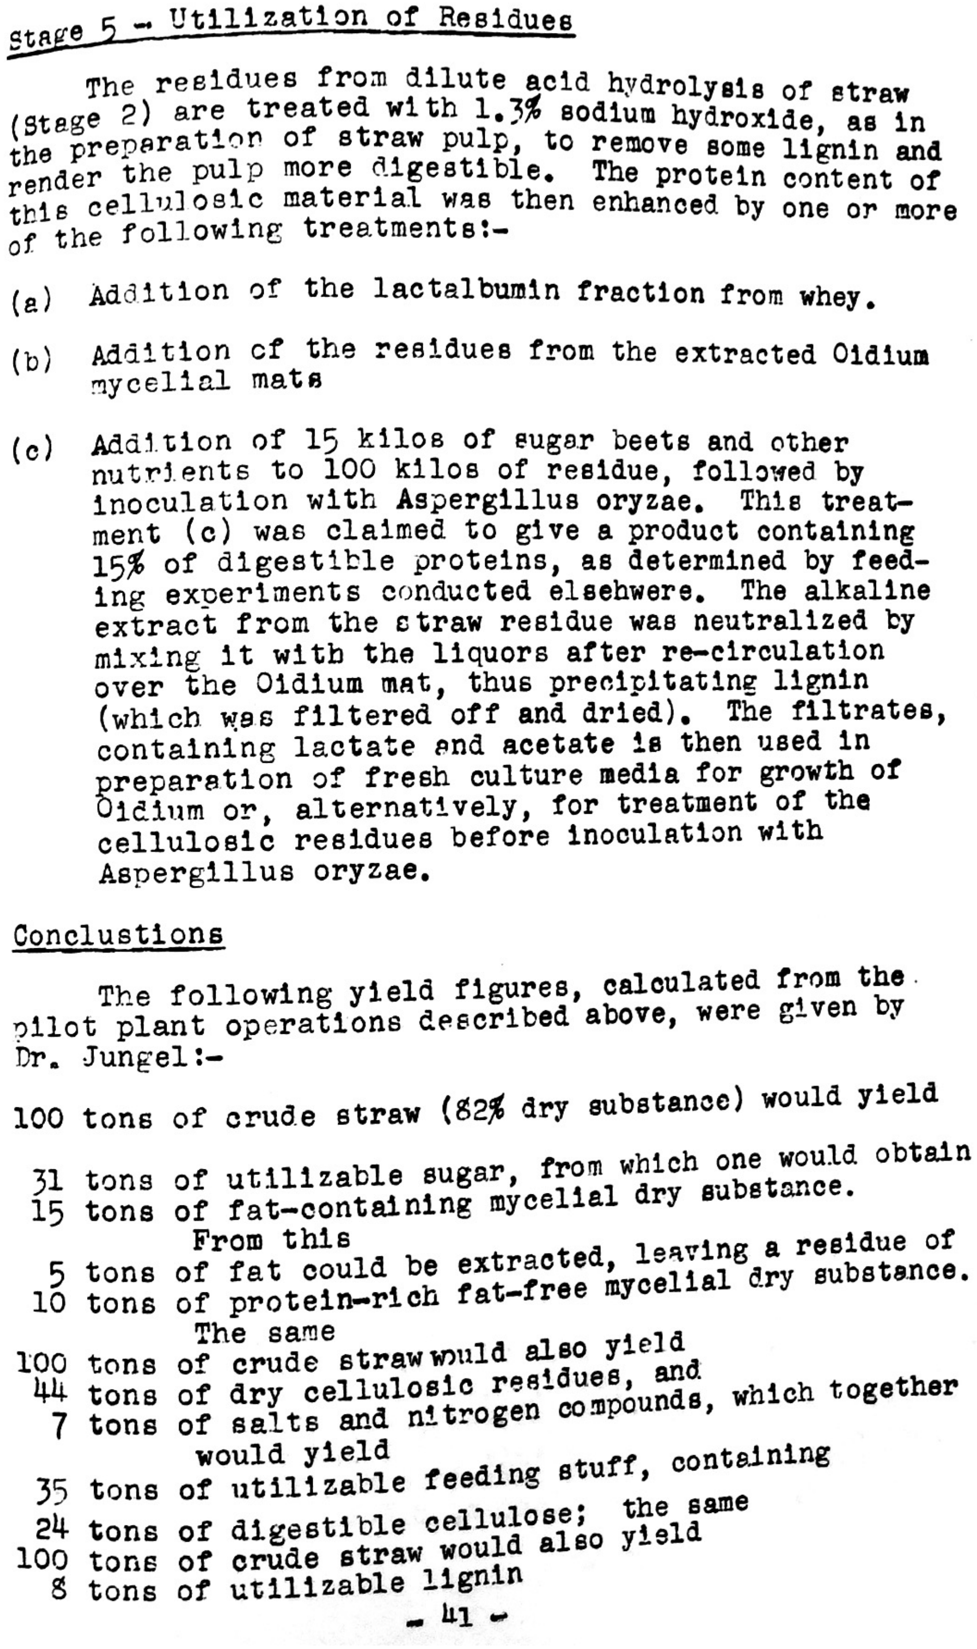
Stage 4 - Fermentation

The organism used was a specially selected strain of *Oidium lactis* (Oosphora lactis). It was grown for test purposes on strips of canvas hung in a wooden chamber. The temperature was thermostatically controlled at 25°C. The solution was sprayed on one side of the canvas sheets and allowed to flow down to a tank from which it was recirculated. Spore inoculum was sprayed on the opposite side of the canvas and a thick mat of mycelium developed. After 5 days growth it was scraped off and treated with methyl alcohol to remove water and liberate the fat. The fat was subsequently extracted with trichlorethylene, after first boiling off the methanol. The same process was used for cultivating the mould on whey.

For larger scale production amodified apparatus was being developed in which the canvas sheets were replaced by a continuous canvas band, fastened at the sides to roller chains which passed over 6 pairs of sprockets, thus giving tortuous path and exposing a large canvas surface. The fermentation medium was distributed, with continuous re-circulation, from a shallow perforated tray at one point on the inside of the canvas band. The fungus developed on the outside where it could be readily scraped off by a stationary knife.

- 40 -

Figure A.15: Biotechnology methods for producing and purifying lipids from cultured yeast [BIOS 236].



Stage 5 - Utilization of Residues

The residues from dilute acid hydrolysis of straw (Stage 2) are treated with 1.3% sodium hydroxide, as in the preparation of straw pulp, to remove some lignin and render the pulp more digestible. The protein content of this cellulosic material was then enhanced by one or more of the following treatments:-

(a) Addition of the lactalbumin fraction from whey.

(b) Addition of the residues from the extracted Oidium mycelial mats

(c) Addition of 15 kilos of sugar beets and other nutrients to 100 kilos of residue, followed by inoculation with Aspergillus oryzae. This treatment (c) was claimed to give a product containing 15% of digestible proteins, as determined by feeding experiments conducted elsehwere. The alkaline extract from the straw residue was neutralized by mixing it with the liquors after re-circulation over the Oidium mat, thus precipitating lignin (which was filtered off and dried). The filtrates, containing lactate and acetate is then used in preparation of fresh culture media for growth of Oidium or, alternatively, for treatment of the cellulosic residues before inoculation with Aspergillus oryzae.

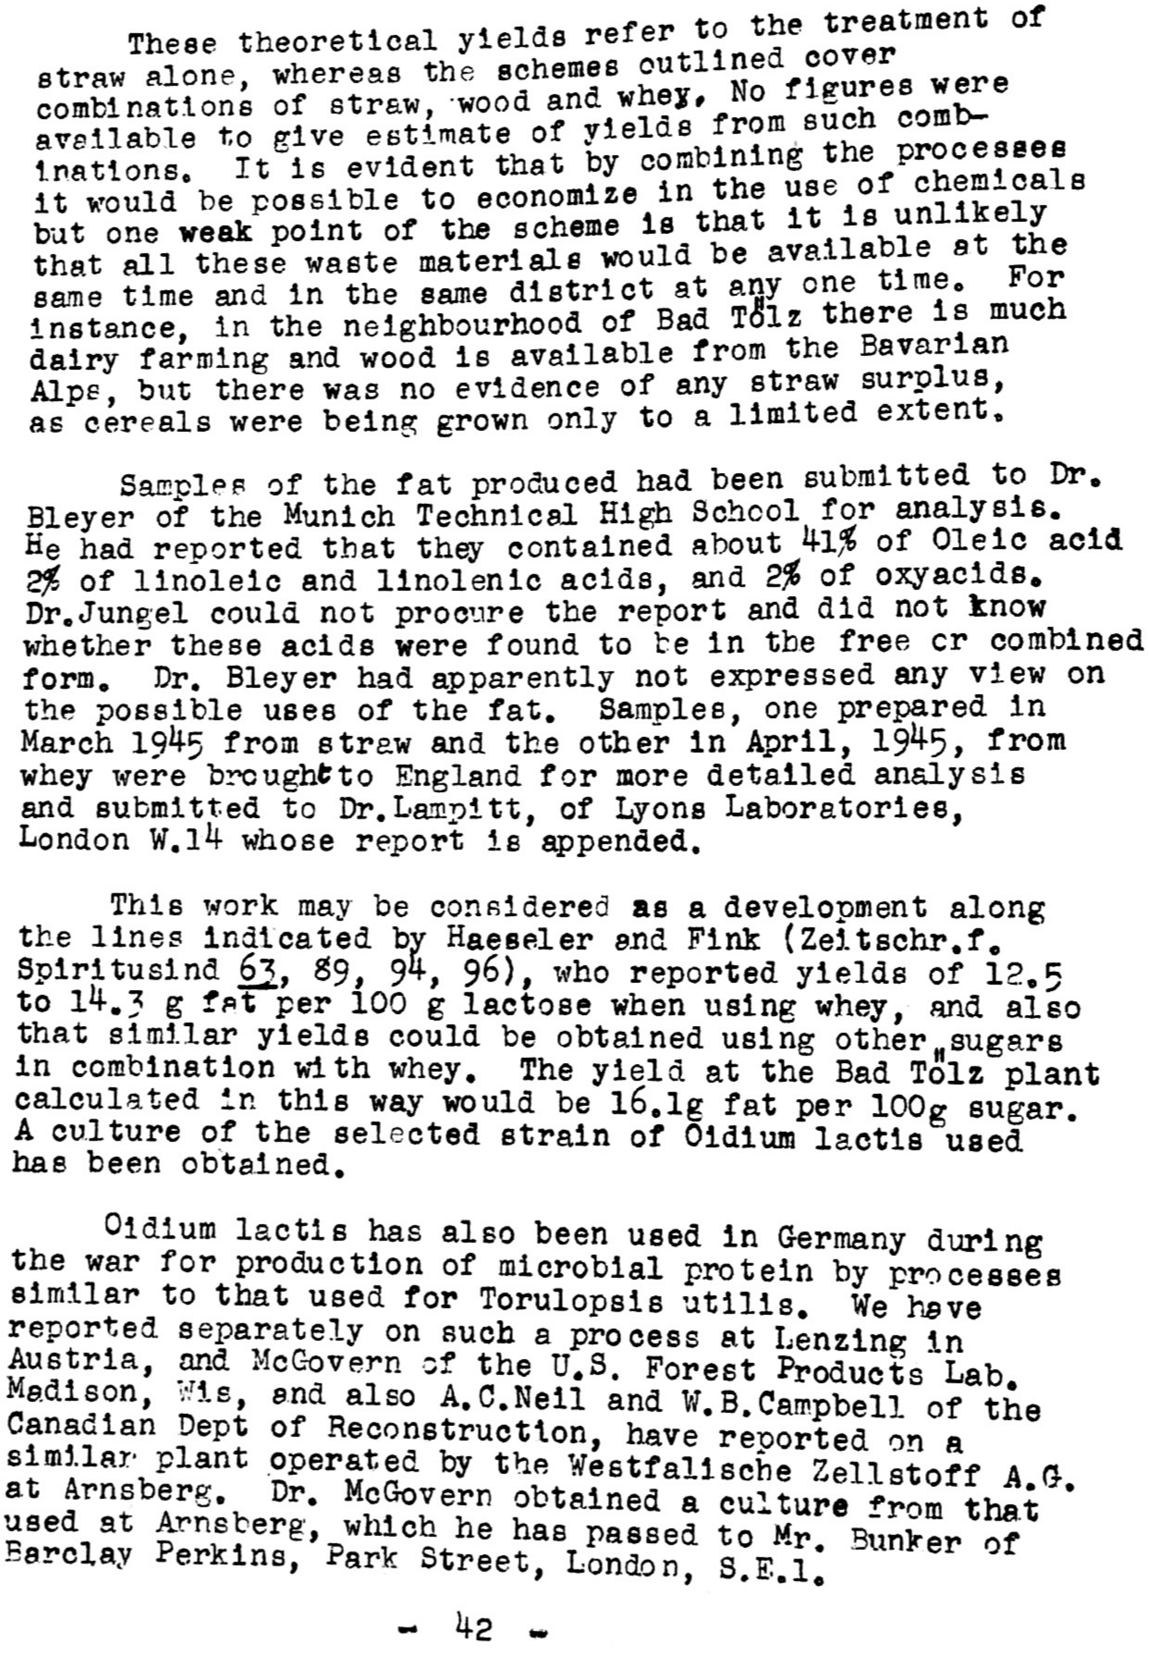
Conclusions

The following yield figures, calculated from the pilot plant operations described above, were given by Dr. Jungel:-

100 tons of crude straw (82% dry substance) would yield

31 tons of utilizable sugar, from which one would obtain
15 tons of fat-containing mycelial dry substance.
From this
5 tons of fat could be extracted, leaving a residue of
10 tons of protein-rich fat-free mycelial dry substance.
The same
100 tons of crude straw would also yield
44 tons of dry cellulosic residues, and
7 tons of salts and nitrogen compounds, which together
would yield
35 tons of utilizable feeding stuff, containing
24 tons of digestible cellulose; the same
100 tons of crude straw would also yield
8 tons of utilizable lignin

Figure A.16: Biotechnology methods for producing and purifying lipids from cultured yeast [BIOS 236].



These theoretical yields refer to the treatment of straw alone, whereas the schemes outlined cover combinations of straw, wood and whey. No figures were available to give estimate of yields from such combinations. It is evident that by combining the processes it would be possible to economize in the use of chemicals but one weak point of the scheme is that it is unlikely that all these waste materials would be available at the same time and in the same district at any one time. For instance, in the neighbourhood of Bad Tölz there is much dairy farming and wood is available from the Bavarian Alps, but there was no evidence of any straw surplus, as cereals were being grown only to a limited extent.

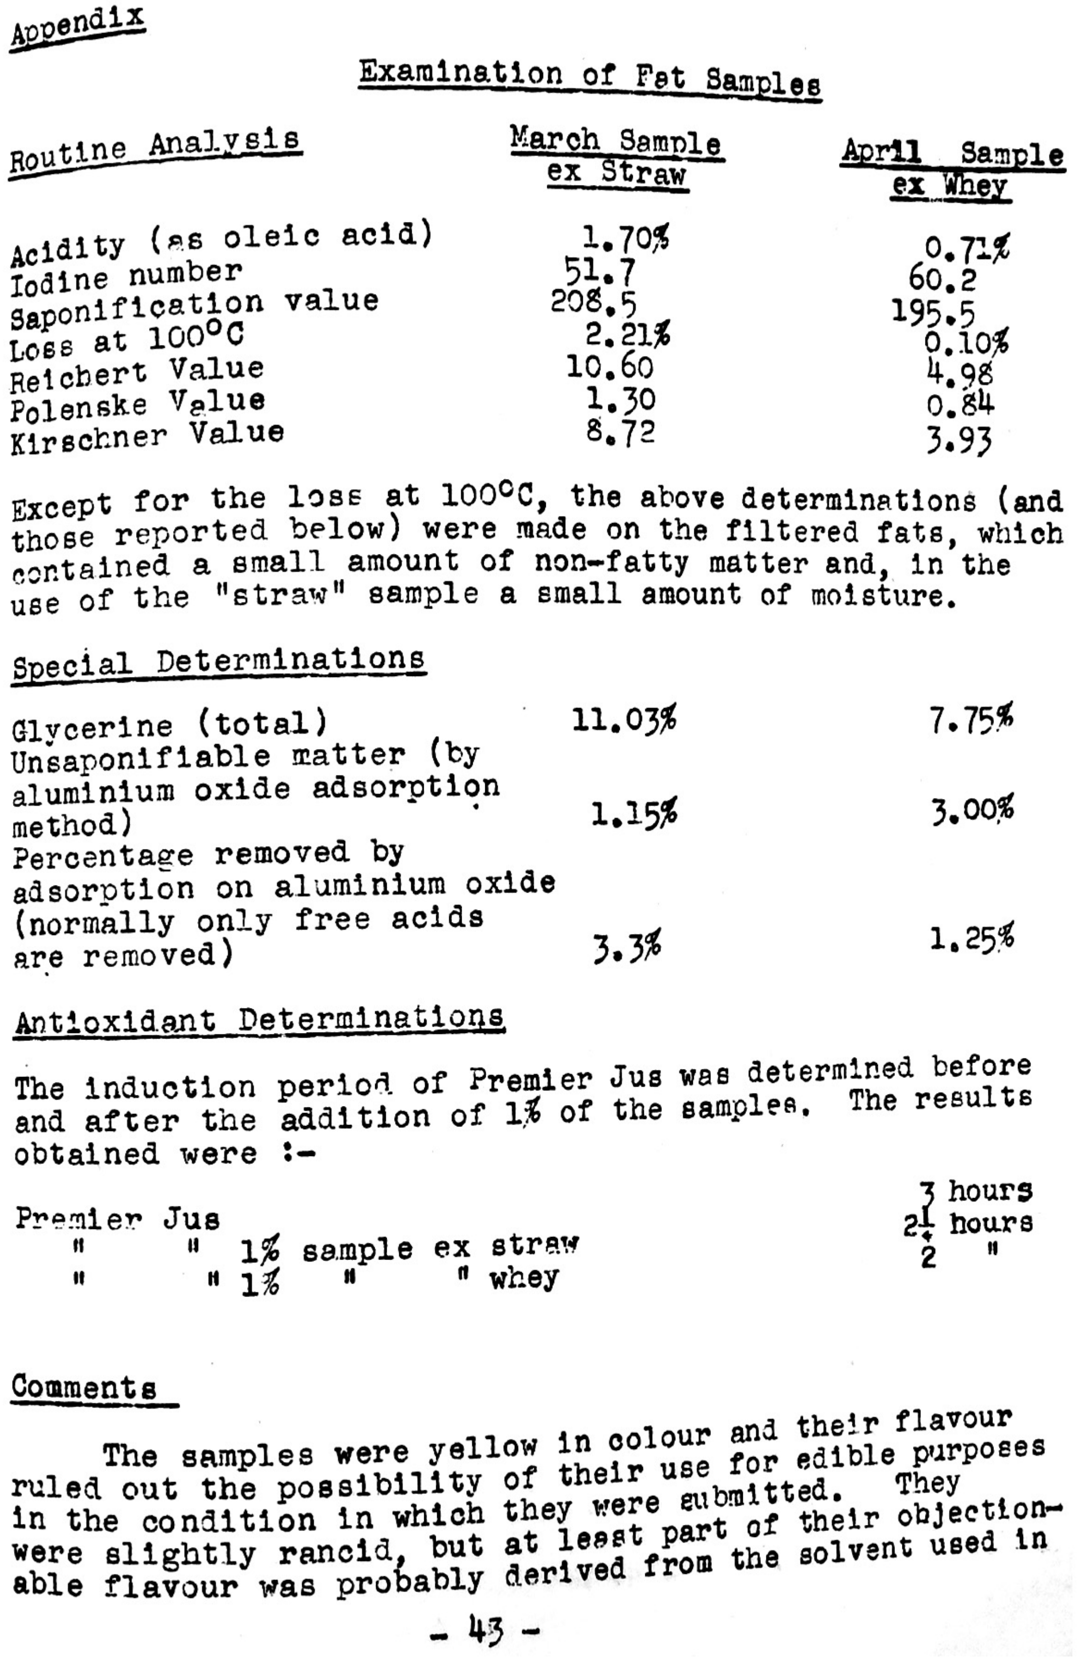
Samples of the fat produced had been submitted to Dr. Bleyer of the Munich Technical High School for analysis. He had reported that they contained about 41% of Oleic acid 2% of linoleic and linolenic acids, and 2% of oxyacids. Dr.Jungel could not procure the report and did not know whether these acids were found to be in the free or combined form. Dr. Bleyer had apparently not expressed any view on the possible uses of the fat. Samples, one prepared in March 1945 from straw and the other in April, 1945, from whey were brought to England for more detailed analysis and submitted to Dr.Lampitt, of Lyons Laboratories, London W.14 whose report is appended.

This work may be considered as a development along the lines indicated by Haeseler and Fink (Zeitschr.f. Spiritusind 63, 89, 94, 96), who reported yields of 12.5 to 14.3 g fat per 100 g lactose when using whey, and also that similar yields could be obtained using other sugars in combination with whey. The yield at the Bad Tölz plant calculated in this way would be 16.1g fat per 100g sugar. A culture of the selected strain of Oidium lactis used has been obtained.

Oidium lactis has also been used in Germany during the war for production of microbial protein by processes similar to that used for Torulopsis utilis. We have reported separately on such a process at Lenzing in Austria, and McGovern of the U.S. Forest Products Lab. Madison, Wis, and also A.C.Neil and W.B.Campbell of the Canadian Dept of Reconstruction, have reported on a similar plant operated by the Westfalische Zellstoff A.G. at Arnsberg. Dr. McGovern obtained a culture from that used at Arnsberg, which he has passed to Mr. Bunker of Barclay Perkins, Park Street, London, S.E.1.

- 42 -

Figure A.17: Biotechnology methods for producing and purifying lipids from cultured yeast [BIOS 236].



Appendix

Examination of Fat Samples

Routine Analysis	March Sample ex Straw	April Sample ex Whey
Acidity (as oleic acid)	1.70%	0.71%
Iodine number	51.7	60.2
Saponification value	208.5	195.5
Loss at 100°C	2.21%	0.10%
Reichert Value	10.60	4.98
Polenske Value	1.30	0.84
Kirschner Value	8.72	3.93

Except for the loss at 100°C, the above determinations (and those reported below) were made on the filtered fats, which contained a small amount of non-fatty matter and, in the use of the "straw" sample a small amount of moisture.

Special Determinations

Glycerine (total)	11.03%	7.75%
Unsaponifiable matter (by aluminium oxide adsorption method)	1.15%	3.00%
Percentage removed by adsorption on aluminium oxide (normally only free acids are removed)	3.3%	1.25%

Antioxidant Determinations

The induction period of Premier Jus was determined before and after the addition of 1% of the samples. The results obtained were :-

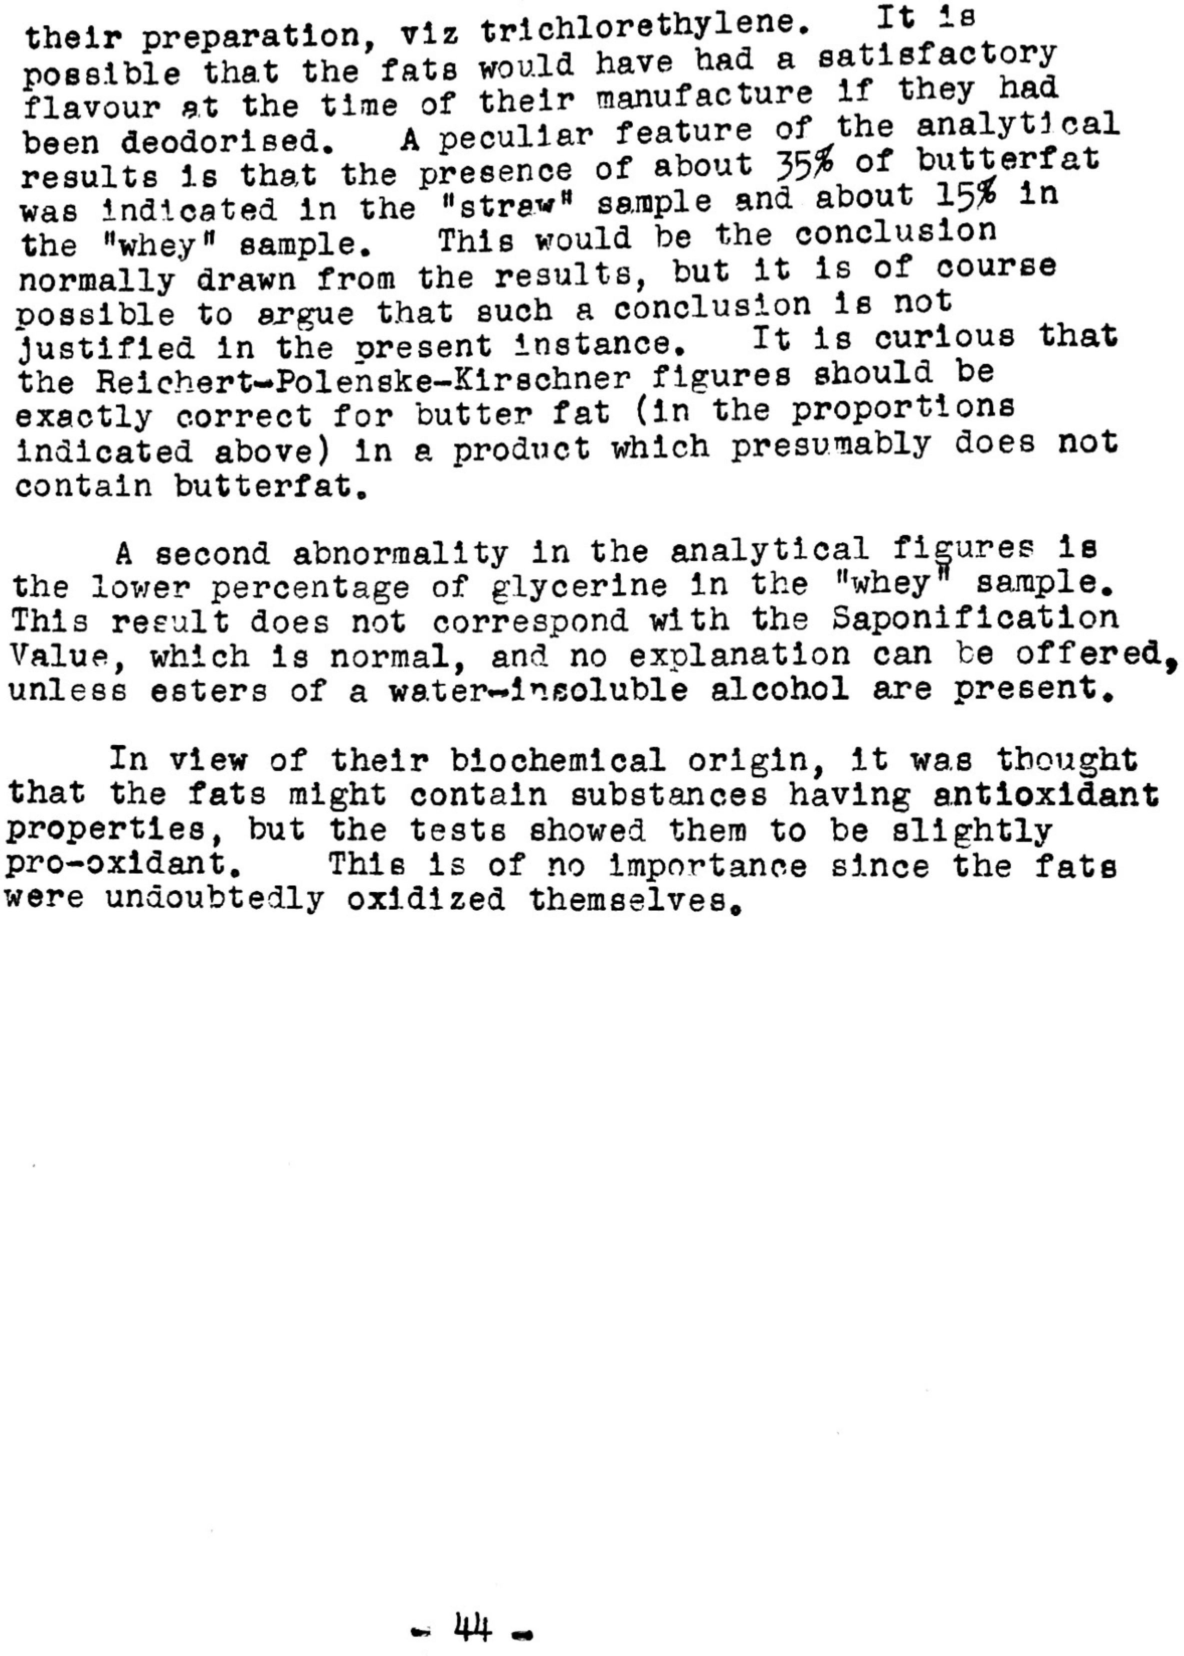
Premier Jus	3 hours
" " 1% sample ex straw	2¼ hours
" " 1% " " whey	2 "

Comments

The samples were yellow in colour and their flavour ruled out the possibility of their use for edible purposes in the condition in which they were submitted. They were slightly rancid, but at least part of their objectionable flavour was probably derived from the solvent used in

- 43 -

Figure A.18: Biotechnology methods for producing and purifying lipids from cultured yeast [BIOS 236].



their preparation, viz trichlorethylene. It is possible that the fats would have had a satisfactory flavour at the time of their manufacture if they had been deodorised. A peculiar feature of the analytical results is that the presence of about 35% of butterfat was indicated in the "straw" sample and about 15% in the "whey" sample. This would be the conclusion normally drawn from the results, but it is of course possible to argue that such a conclusion is not justified in the present instance. It is curious that the Reichert-Polenske-Kirschner figures should be exactly correct for butter fat (in the proportions indicated above) in a product which presumably does not contain butterfat.

A second abnormality in the analytical figures is the lower percentage of glycerine in the "whey" sample. This result does not correspond with the Saponification Value, which is normal, and no explanation can be offered, unless esters of a water-insoluble alcohol are present.

In view of their biochemical origin, it was thought that the fats might contain substances having antioxidant properties, but the tests showed them to be slightly pro-oxidant. This is of no importance since the fats were undoubtedly oxidized themselves.

PERISTON

(Name ges. geschuetzt)

Blutfluessigkeitsersatz
(Hergestellt in unserem Werk Elberfeld)

"BAYER"
I.G.Farbenindustrie Aktiengesellschaft
LEVERKUSEN

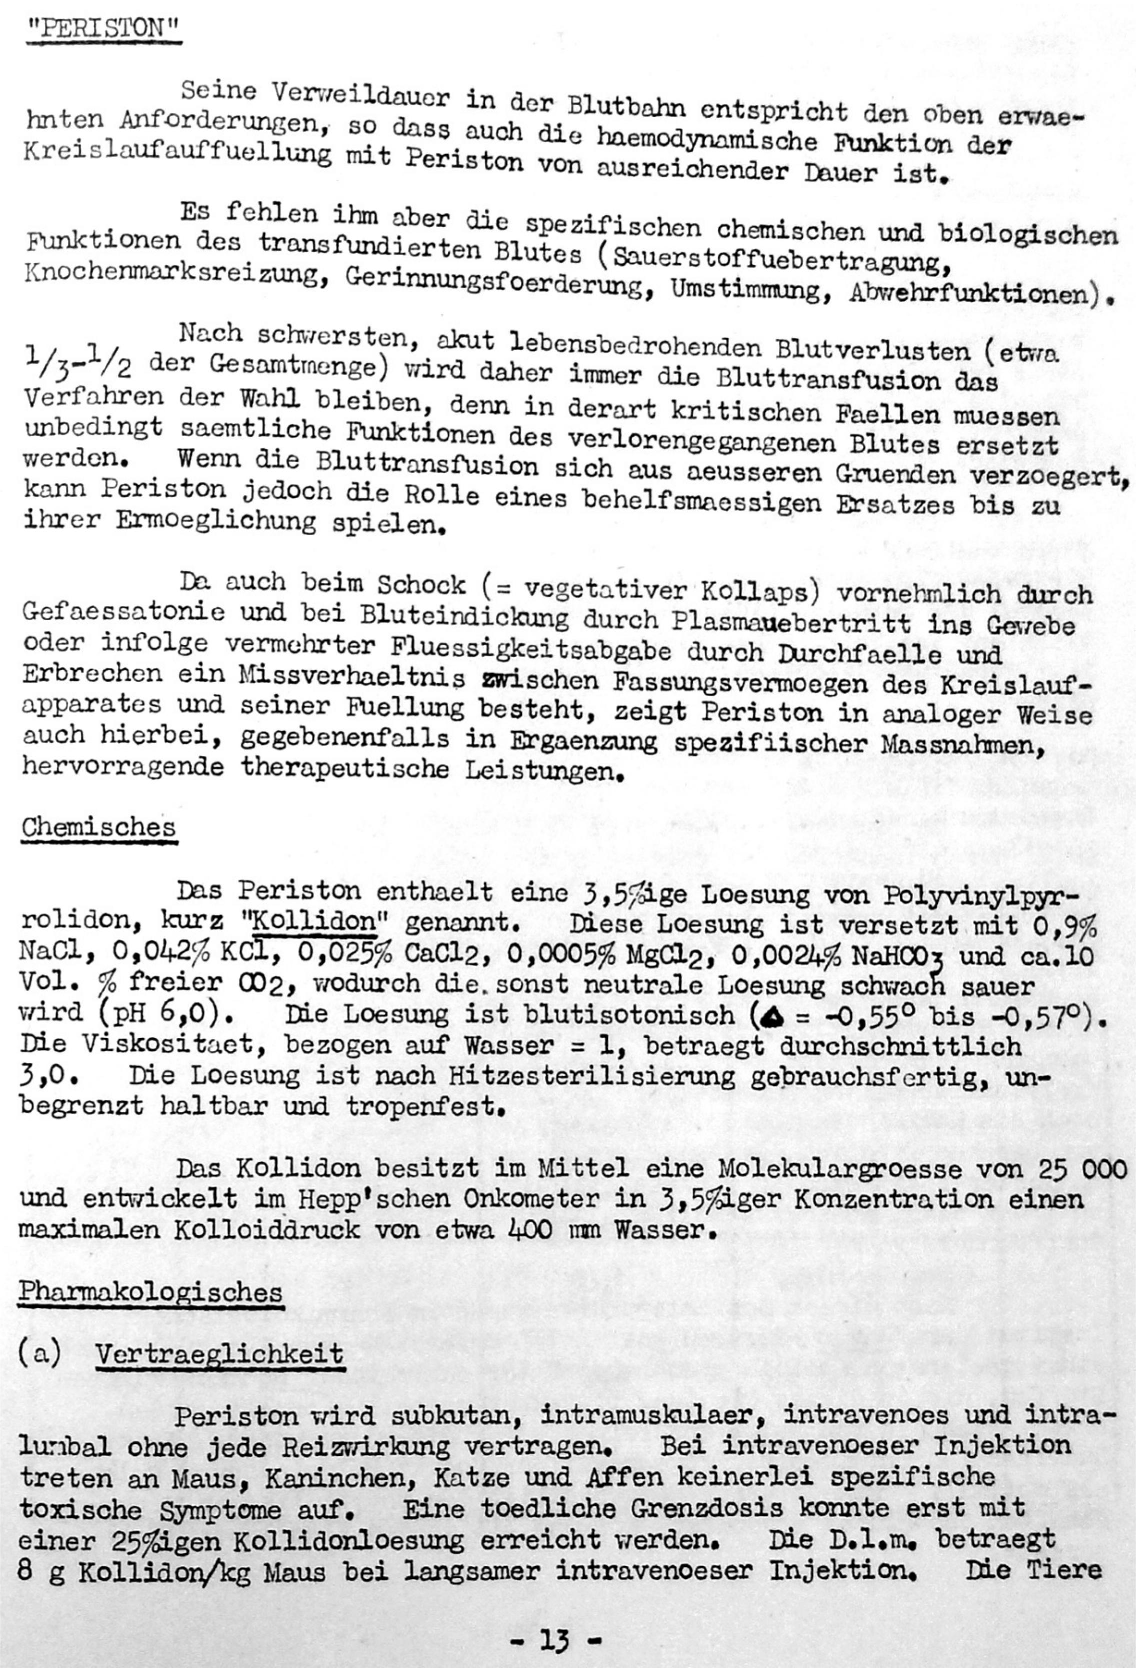
Die Folgen schweren Blutverlustes aeussern sich zunaechst in einem Erlahmen des Kreislaufes, Dieser Kreislaufkollaps ist bei akuten Blutungen bis zum Verlust etwa $^{1}/_{3}$-$^{1}/_{2}$ der zirkulierenden Blutmenge lediglich die Folge des Fuellungsverlustes des Gefaesssystems, also ein rein haemodynamisches Geschehen. Erst bei noch staerkeren akuten Blutungen macht sich zusaetzlich auch der Verlust an Erythrozyten bzw. Haemoglobin, dem Sauerstoffuebertraeger, geltend. Es kommt zur Gewebserstickung, der das Vasomotoren- und Atemzentrum zuerst erliegen.

Jede Substitutionstherapie nach Blutungen muss folglich zunaechst den Kreislauf aufzufuellen versuchen. Hierbei erscheint die intravenoese Verabfolgung ausreichender Mengen solcher Fluessigkeiten am aussichtsreichsten, die reaktionslos vertragen und womoeglich tagelang im Gefaesssystem festgehalten werden, bis die physiologischen Regulationen die normale Blutmenge nach Blutungen wieder ergaenzt haben.

Bisher wurde nach starken Blutverlusten in erster Linie versucht, den Kreislauf durch Infusion physiologischer Salzloesungen zu stuetzen. Derartige Loesungen werden zwar gut vertragen, sie wirken zunaechst auch ausreichend. Ihre Wirkung ist aber viel zu fluechtig, denn nach laengstens 2 Stunden haben diese Salzloesungen die Gefaesswaende durchwandert, und der Kreislauf ist wieder an Fluessigkeit verarmt. Um Salzloesungen ueber viele Stunden, evtl. Tage im Kreislauf zu halten, muessen sie ausser den physiologischen Salzen noch ein Kolloid enthalten, welches Wasser bindet. Zur Vermeidung von Ueberempfindlichkeits-Reaktionen darf dieses keinen Allergencharakter besitzen. Das Kolloidmolekuel muss mit seiner Wasserhuelle so gross sein, dass es selbst die geschaedigte Gefaessmembran nich zu durchwandern vermag (Bayliss).

Nach diesen Gesichtspunkten wurde im Pharmakologischen Institut der "Bayer"-Forschungsstaetten unseres Werkes Elberfeld nach einem geeigneten Kolloid gesucht. Unter zahlreichen hochmolekularen Stoffen, die in dieser Richtung tierexperimentell geprueft wurden, erwies sich das von Reppe und seinen Mitarbeitern in unserem Werk Ludwigshafen entwickelte Polymerisationsprodukt Polyvinylpyrrolidon als optimal. Eine hieraus hergestellte, den physikalischen Eigenschaften des Blutes angepasste Loesung bildet den Blutfluessigkeitsersatz.

Figure A.24: A report on periston synthetic blood plasma [BIOS 354].



"PERISTON"

Seine Verweildauer in der Blutbahn entspricht den oben erwaehnten Anforderungen, so dass auch die haemodynamische Funktion der Kreislaufauffuellung mit Periston von ausreichender Dauer ist.

Es fehlen ihm aber die spezifischen chemischen und biologischen Funktionen des transfundierten Blutes (Sauerstoffuebertragung, Knochenmarksreizung, Gerinnungsfoerderung, Umstimmung, Abwehrfunktionen).

Nach schwersten, akut lebensbedrohenden Blutverlusten (etwa $1/3$-$1/2$ der Gesamtmenge) wird daher immer die Bluttransfusion das Verfahren der Wahl bleiben, denn in derart kritischen Faellen muessen unbedingt saemtliche Funktionen des verlorengegangenen Blutes ersetzt werden. Wenn die Bluttransfusion sich aus aeusseren Gruenden verzoegert, kann Periston jedoch die Rolle eines behelfsmaessigen Ersatzes bis zu ihrer Ermoeglichung spielen.

Da auch beim Schock (= vegetativer Kollaps) vornehmlich durch Gefaessatonie und bei Bluteindickung durch Plasmauebertritt ins Gewebe oder infolge vermehrter Fluessigkeitsabgabe durch Durchfaelle und Erbrechen ein Missverhaeltnis zwischen Fassungsvermoegen des Kreislaufapparates und seiner Fuellung besteht, zeigt Periston in analoger Weise auch hierbei, gegebenenfalls in Ergaenzung spezifiischer Massnahmen, hervorragende therapeutische Leistungen.

Chemisches

Das Periston enthaelt eine 3,5%ige Loesung von Polyvinylpyrrolidon, kurz "Kollidon" genannt. Diese Loesung ist versetzt mit 0,9% NaCl, 0,042% KCl, 0,025% $CaCl_2$, 0,0005% $MgCl_2$, 0,0024% $NaHCO_3$ und ca. 10 Vol. % freier CO_2, wodurch die sonst neutrale Loesung schwach sauer wird (pH 6,0). Die Loesung ist blutisotonisch (Δ = -0,55° bis -0,57°). Die Viskositaet, bezogen auf Wasser = 1, betraegt durchschnittlich 3,0. Die Loesung ist nach Hitzesterilisierung gebrauchsfertig, unbegrenzt haltbar und tropenfest.

Das Kollidon besitzt im Mittel eine Molekulargroesse von 25 000 und entwickelt im Hepp'schen Onkometer in 3,5%iger Konzentration einen maximalen Kolloiddruck von etwa 400 mm Wasser.

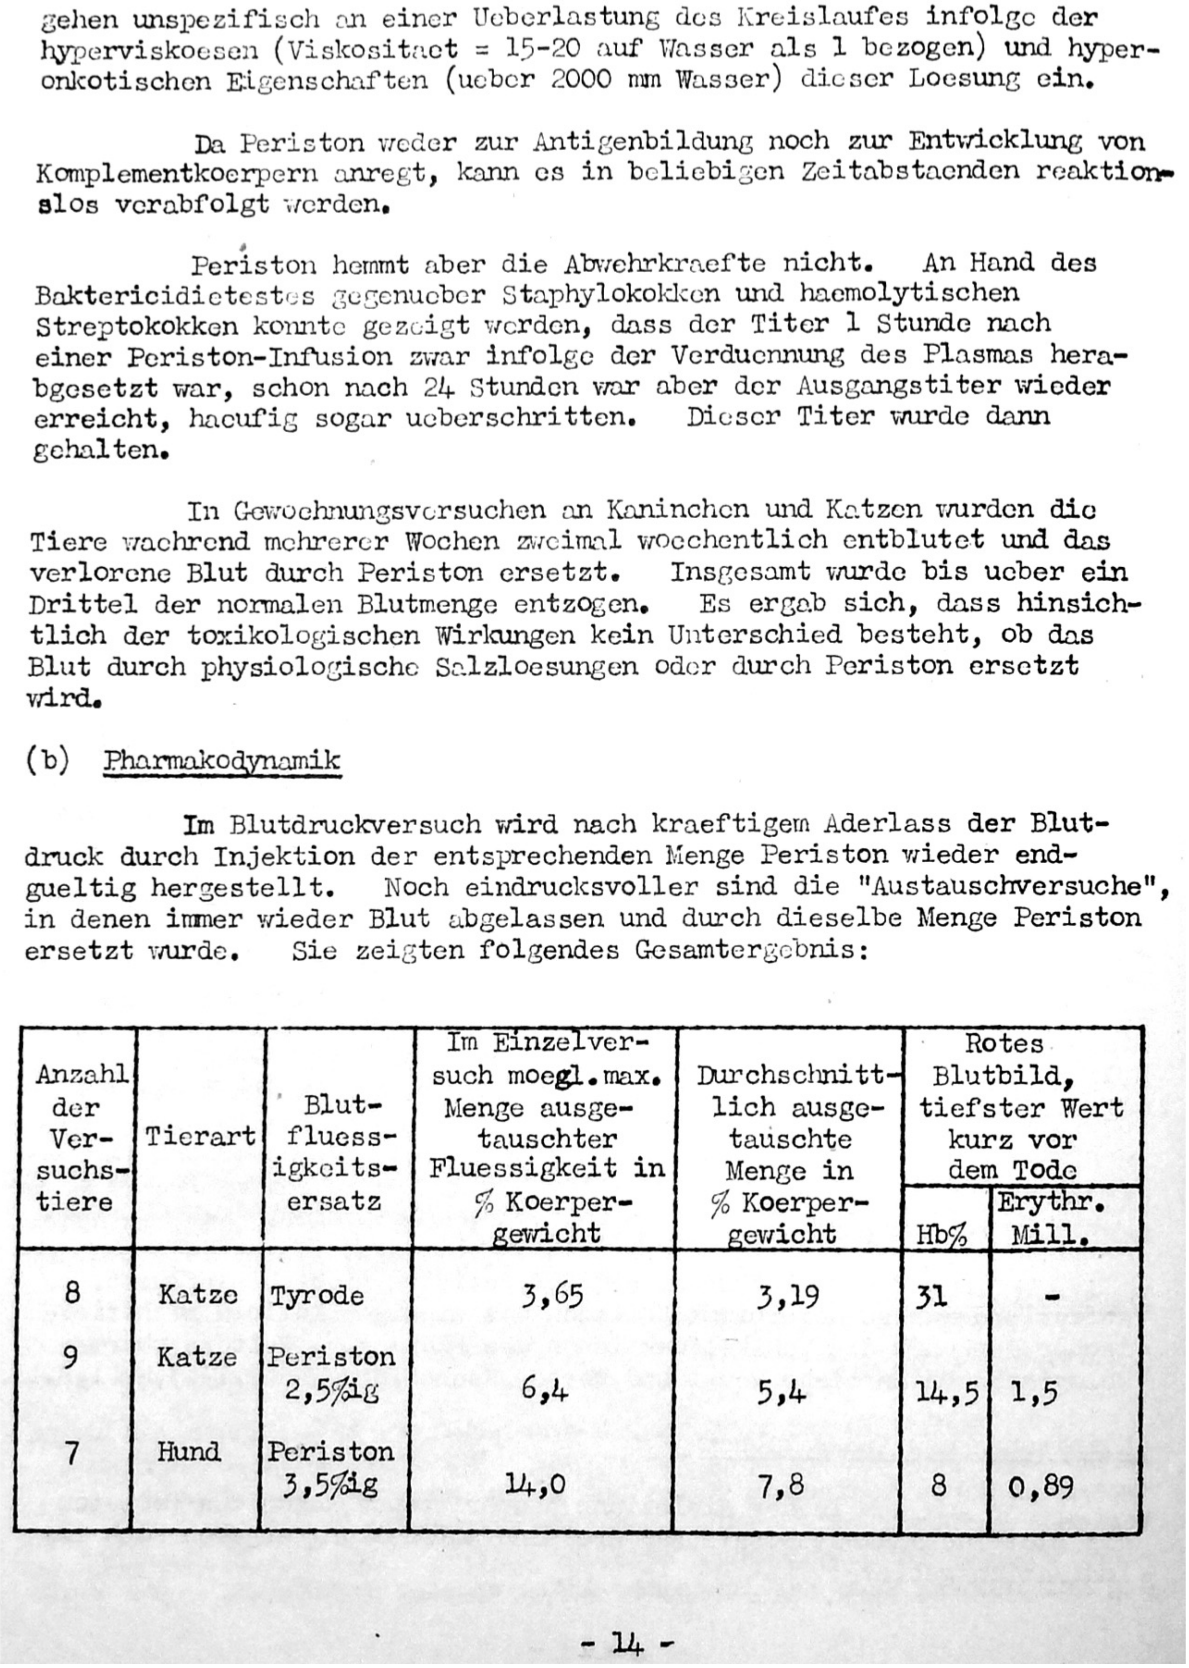
Pharmakologisches

(a) Vertraeglichkeit

Periston wird subkutan, intramuskulaer, intravenoes und intralumbal ohne jede Reizwirkung vertragen. Bei intravenoeser Injektion treten an Maus, Kaninchen, Katze und Affen keinerlei spezifische toxische Symptome auf. Eine toedliche Grenzdosis konnte erst mit einer 25%igen Kollidonloesung erreicht werden. Die D.l.m. betraegt 8 g Kollidon/kg Maus bei langsamer intravenoeser Injektion. Die Tiere

- 13 -

Figure A.25: A report on periston synthetic blood plasma [BIOS 354].



gehen unspezifisch an einer Ueberlastung des Kreislaufes infolge der hyperviskoesen (Viskositaet = 15-20 auf Wasser als 1 bezogen) und hyperonkotischen Eigenschaften (ueber 2000 mm Wasser) dieser Loesung ein.

Da Periston weder zur Antigenbildung noch zur Entwicklung von Komplementkoerpern anregt, kann es in beliebigen Zeitabstaenden reaktionslos verabfolgt werden.

Periston hemmt aber die Abwehrkraefte nicht. An Hand des Baktericidietestes gegenueber Staphylokokken und haemolytischen Streptokokken konnte gezeigt werden, dass der Titer 1 Stunde nach einer Periston-Infusion zwar infolge der Verduennung des Plasmas herabgesetzt war, schon nach 24 Stunden war aber der Ausgangstiter wieder erreicht, haeufig sogar ueberschritten. Dieser Titer wurde dann gehalten.

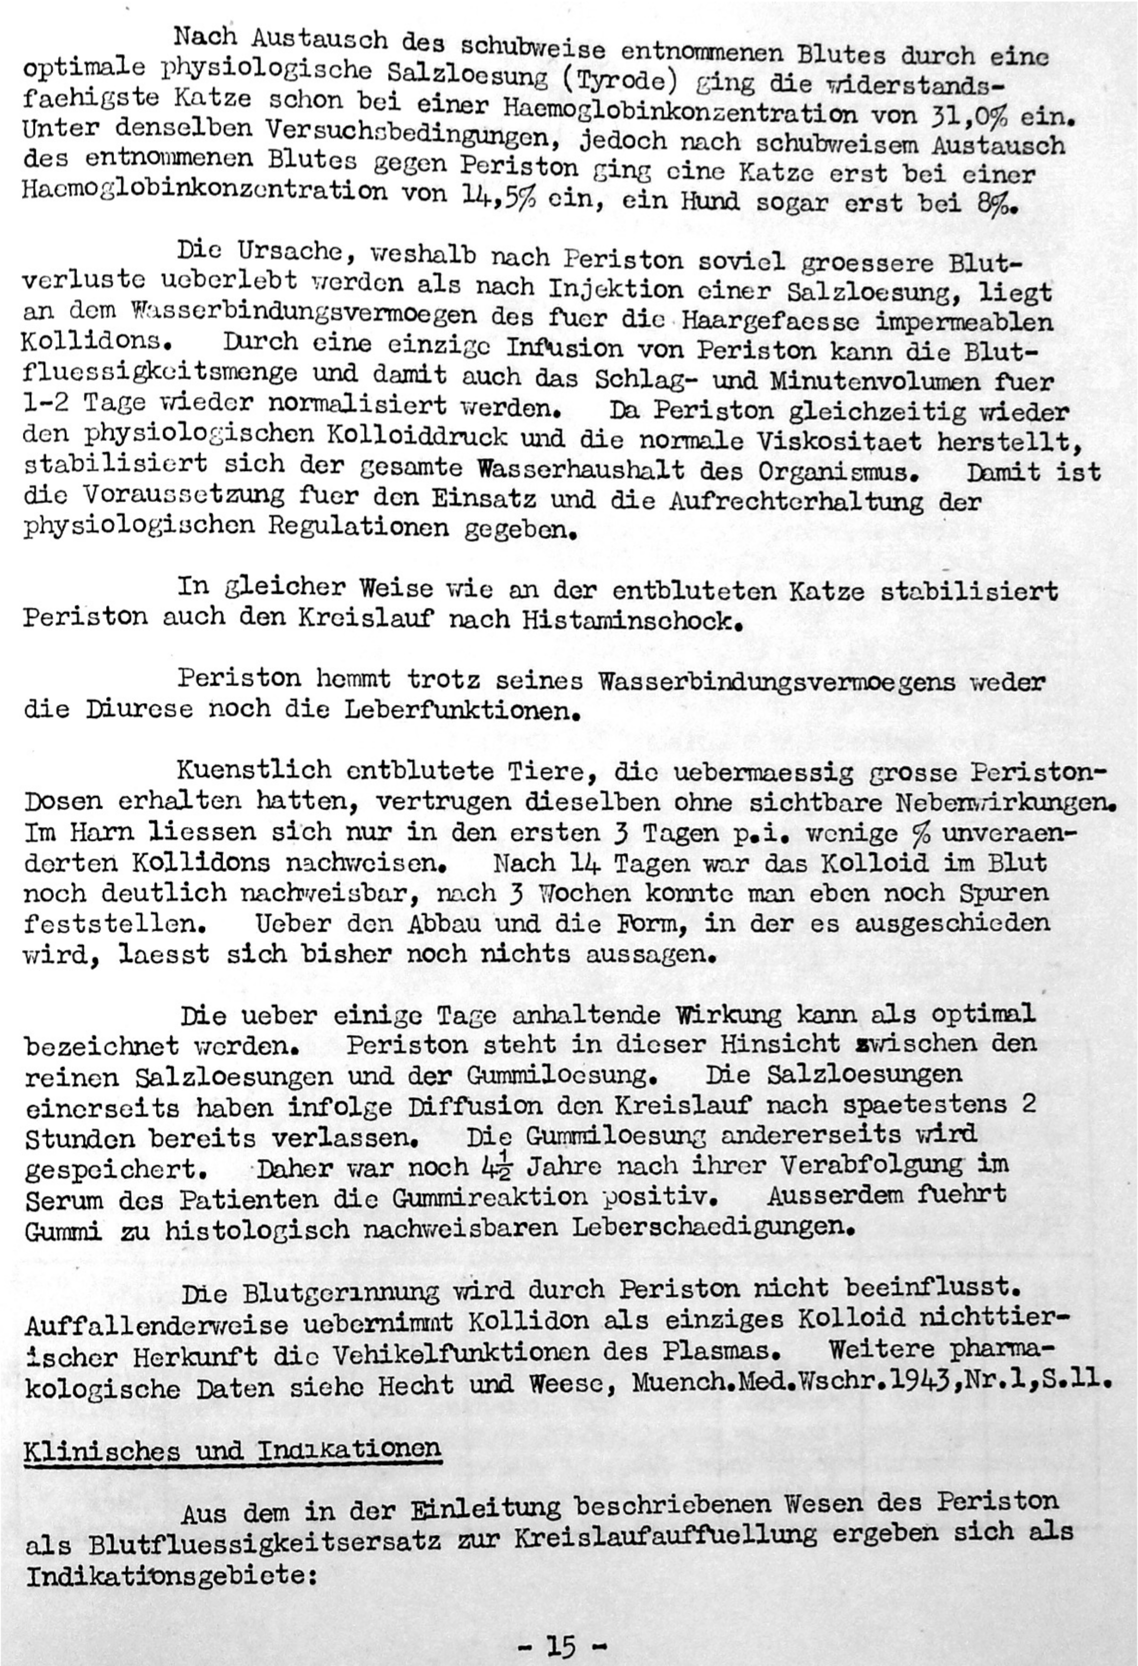
In Gewoehnungsversuchen an Kaninchen und Katzen wurden die Tiere waehrend mehrerer Wochen zweimal woechentlich entblutet und das verlorene Blut durch Periston ersetzt. Insgesamt wurde bis ueber ein Drittel der normalen Blutmenge entzogen. Es ergab sich, dass hinsichtlich der toxikologischen Wirkungen kein Unterschied besteht, ob das Blut durch physiologische Salzloesungen oder durch Periston ersetzt wird.

(b) Pharmakodynamik

Im Blutdruckversuch wird nach kraeftigem Aderlass der Blutdruck durch Injektion der entsprechenden Menge Periston wieder endgueltig hergestellt. Noch eindrucksvoller sind die "Austauschversuche", in denen immer wieder Blut abgelassen und durch dieselbe Menge Periston ersetzt wurde. Sie zeigten folgendes Gesamtergebnis:

Anzahl der Versuchstiere	Tierart	Blutfluessigkeitsersatz	Im Einzelversuch moegl. max. Menge ausgetauschter Fluessigkeit in % Koerpergewicht	Durchschnittlich ausgetauschte Menge in % Koerpergewicht	Rotes Blutbild, tiefster Wert kurz vor dem Tode	
					Hb%	Erythr. Mill.
8	Katze	Tyrode	3,65	3,19	31	-
9	Katze	Periston 2,5%ig	6,4	5,4	14,5	1,5
7	Hund	Periston 3,5%ig	14,0	7,8	8	0,89

Figure A.26: A report on periston synthetic blood plasma [BIOS 354].



Nach Austausch des schubweise entnommenen Blutes durch eine optimale physiologische Salzloesung (Tyrode) ging die widerstandsfaehigste Katze schon bei einer Haemoglobinkonzentration von 31,0% ein. Unter denselben Versuchsbedingungen, jedoch nach schubweisem Austausch des entnommenen Blutes gegen Periston ging eine Katze erst bei einer Haemoglobinkonzentration von 14,5% ein, ein Hund sogar erst bei 8%.

Die Ursache, weshalb nach Periston soviel groessere Blutverluste ueberlebt werden als nach Injektion einer Salzloesung, liegt an dem Wasserbindungsvermoegen des fuer die Haargefaesse impermeablen Kollidons. Durch eine einzige Infusion von Periston kann die Blutfluessigkeitsmenge und damit auch das Schlag- und Minutenvolumen fuer 1-2 Tage wieder normalisiert werden. Da Periston gleichzeitig wieder den physiologischen Kolloiddruck und die normale Viskositaet herstellt, stabilisiert sich der gesamte Wasserhaushalt des Organismus. Damit ist die Voraussetzung fuer den Einsatz und die Aufrechterhaltung der physiologischen Regulationen gegeben.

In gleicher Weise wie an der entbluteten Katze stabilisiert Periston auch den Kreislauf nach Histaminschock.

Periston hemmt trotz seines Wasserbindungsvermoegens weder die Diurese noch die Leberfunktionen.

Kuenstlich entblutete Tiere, die uebermaessig grosse Periston-Dosen erhalten hatten, vertrugen dieselben ohne sichtbare Nebenwirkungen. Im Harn liessen sich nur in den ersten 3 Tagen p.i. wenige % unveraenderten Kollidons nachweisen. Nach 14 Tagen war das Kolloid im Blut noch deutlich nachweisbar, nach 3 Wochen konnte man eben noch Spuren feststellen. Ueber den Abbau und die Form, in der es ausgeschieden wird, laesst sich bisher noch nichts aussagen.

Die ueber einige Tage anhaltende Wirkung kann als optimal bezeichnet werden. Periston steht in dieser Hinsicht zwischen den reinen Salzloesungen und der Gummiloesung. Die Salzloesungen einerseits haben infolge Diffusion den Kreislauf nach spaetestens 2 Stunden bereits verlassen. Die Gummiloesung andererseits wird gespeichert. Daher war noch 4½ Jahre nach ihrer Verabfolgung im Serum des Patienten die Gummireaktion positiv. Ausserdem fuehrt Gummi zu histologisch nachweisbaren Leberschaedigungen.

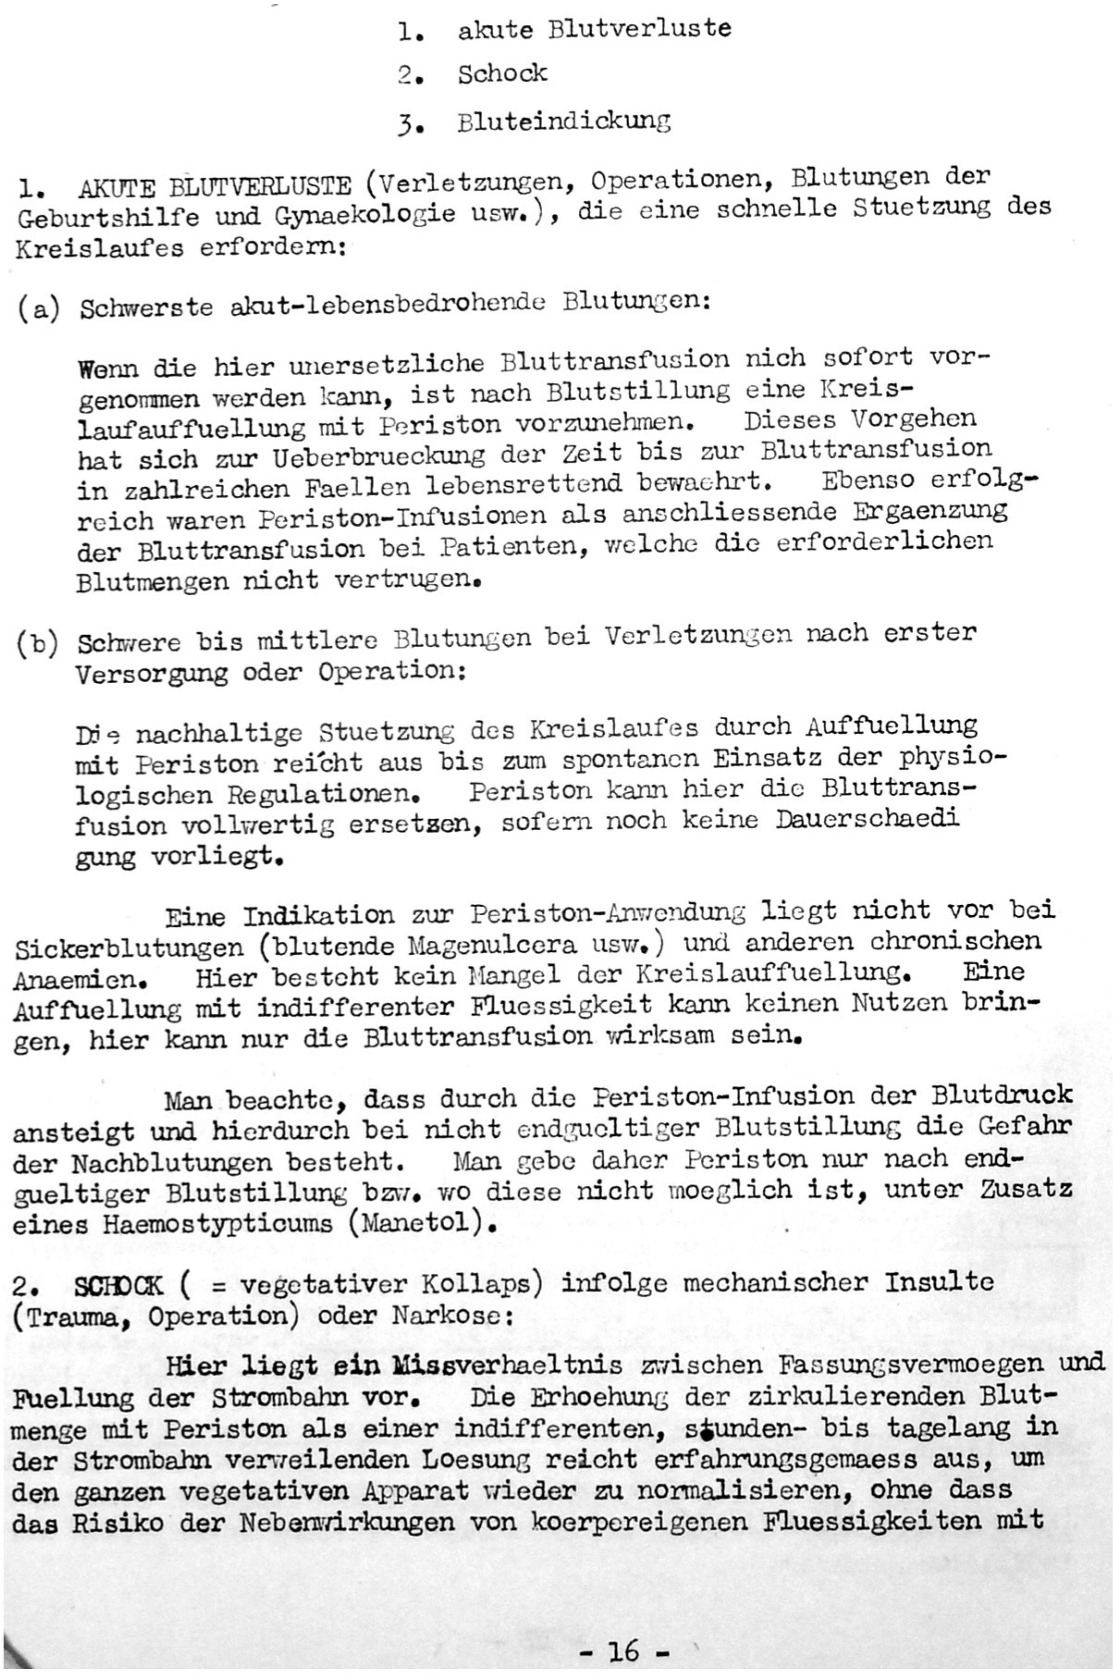
Die Blutgerinnung wird durch Periston nicht beeinflusst. Auffallenderweise uebernimmt Kollidon als einziges Kolloid nichttierischer Herkunft die Vehikelfunktionen des Plasmas. Weitere pharmakologische Daten siehe Hecht und Weese, Muench.Med.Wschr.1943,Nr.1,S.11.

Klinisches und Indikationen

Aus dem in der Einleitung beschriebenen Wesen des Periston als Blutfluessigkeitsersatz zur Kreislaufauffuellung ergeben sich als Indikationsgebiete:

- 15 -

Figure A.27: A report on periston synthetic blood plasma [BIOS 354].



1. akute Blutverluste
2. Schock
3. Bluteindickung

1. AKUTE BLUTVERLUSTE (Verletzungen, Operationen, Blutungen der Geburtshilfe und Gynaekologie usw.), die eine schnelle Stuetzung des Kreislaufes erfordern:

(a) Schwerste akut-lebensbedrohende Blutungen:

Wenn die hier unersetzliche Bluttransfusion nich sofort vorgenommen werden kann, ist nach Blutstillung eine Kreislaufauffuellung mit Periston vorzunehmen. Dieses Vorgehen hat sich zur Ueberbrueckung der Zeit bis zur Bluttransfusion in zahlreichen Faellen lebensrettend bewaehrt. Ebenso erfolgreich waren Periston-Infusionen als anschliessende Ergaenzung der Bluttransfusion bei Patienten, welche die erforderlichen Blutmengen nicht vertrugen.

(b) Schwere bis mittlere Blutungen bei Verletzungen nach erster Versorgung oder Operation:

Die nachhaltige Stuetzung des Kreislaufes durch Auffuellung mit Periston reicht aus bis zum spontanen Einsatz der physiologischen Regulationen. Periston kann hier die Bluttransfusion vollwertig ersetzen, sofern noch keine Dauerschaedigung vorliegt.

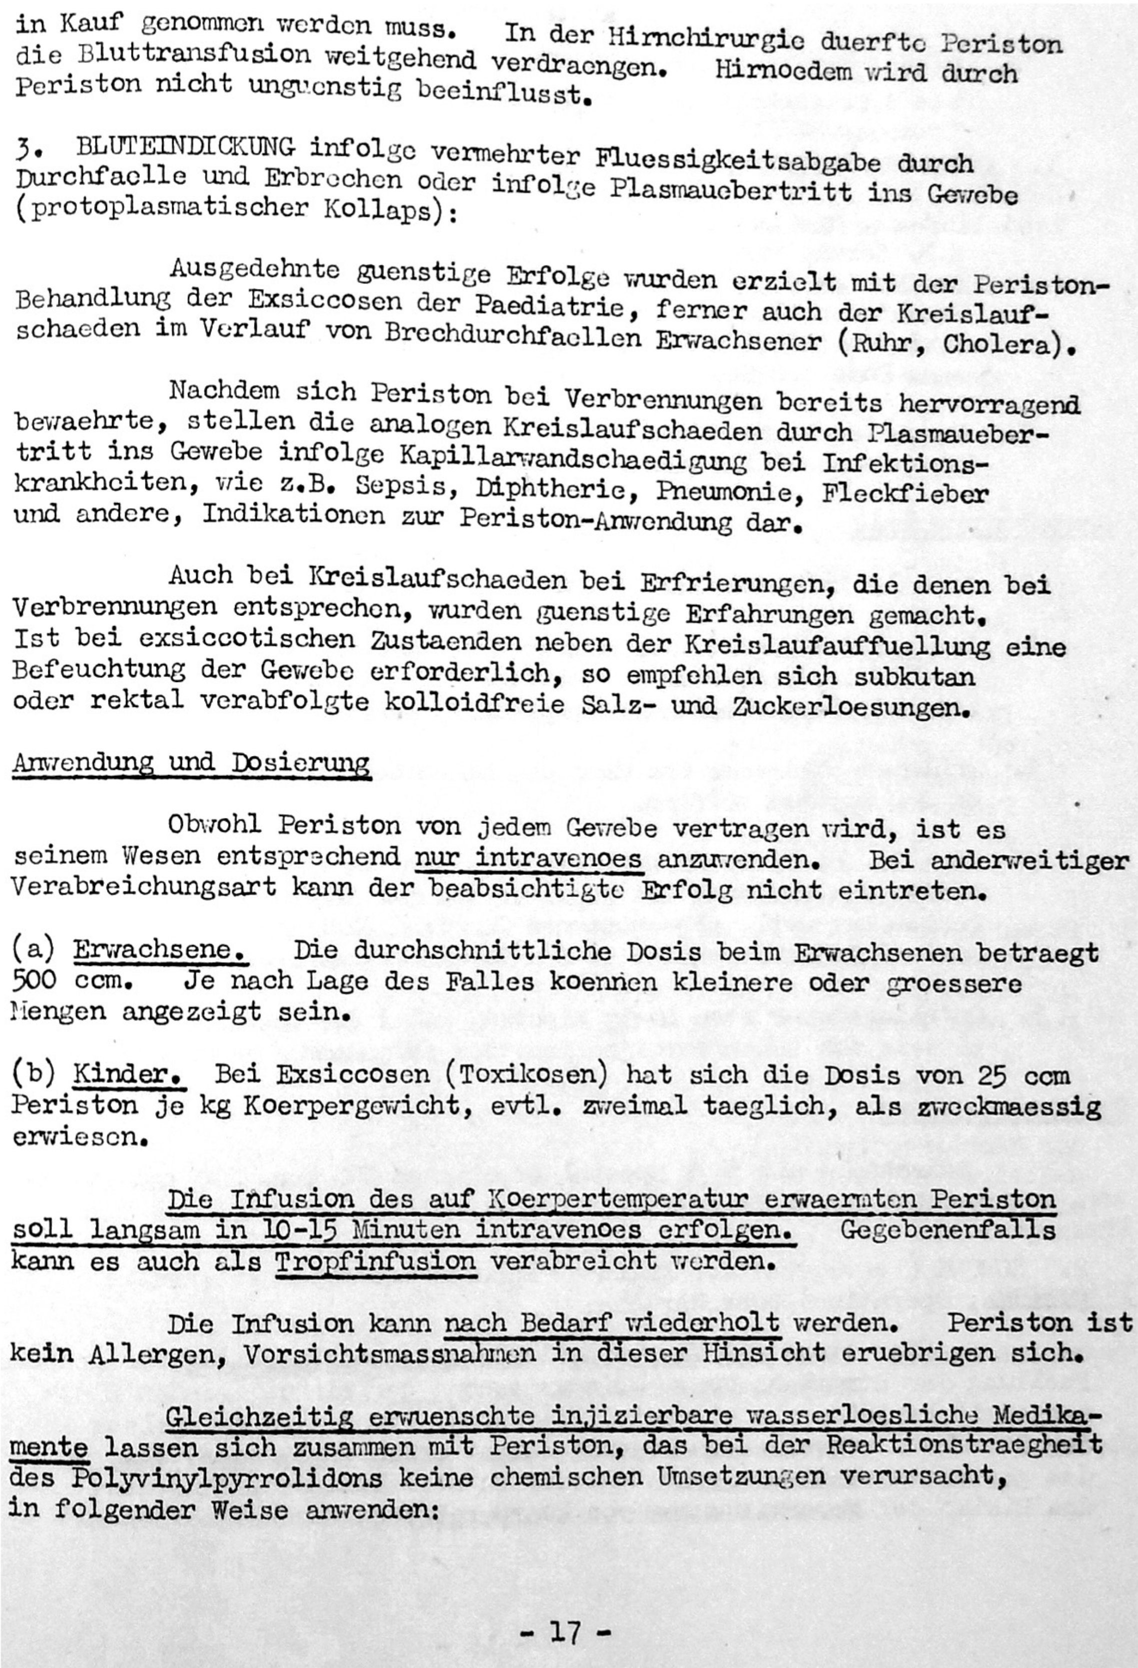
Eine Indikation zur Periston-Anwendung liegt nicht vor bei Sickerblutungen (blutende Magenulcera usw.) und anderen chronischen Anaemien. Hier besteht kein Mangel der Kreislaufauffuellung. Eine Auffuellung mit indifferenter Fluessigkeit kann keinen Nutzen bringen, hier kann nur die Bluttransfusion wirksam sein.

Man beachte, dass durch die Periston-Infusion der Blutdruck ansteigt und hierdurch bei nicht endgueltiger Blutstillung die Gefahr der Nachblutungen besteht. Man gebe daher Periston nur nach endgueltiger Blutstillung bzw. wo diese nicht moeglich ist, unter Zusatz eines Haemostypticums (Manetol).

2. SCHOCK (= vegetativer Kollaps) infolge mechanischer Insulte (Trauma, Operation) oder Narkose:

Hier liegt ein Missverhaeltnis zwischen Fassungsvermoegen und Fuellung der Strombahn vor. Die Erhoehung der zirkulierenden Blutmenge mit Periston als einer indifferenten, stunden- bis tagelang in der Strombahn verweilenden Loesung reicht erfahrungsgemaess aus, um den ganzen vegetativen Apparat wieder zu normalisieren, ohne dass das Risiko der Nebenwirkungen von koerpereigenen Fluessigkeiten mit

Figure A.28: A report on periston synthetic blood plasma [BIOS 354].



in Kauf genommen werden muss. In der Hirnchirurgie duerfte Periston die Bluttransfusion weitgehend verdraengen. Hirnoedem wird durch Periston nicht unguenstig beeinflusst.

3. BLUTEINDICKUNG infolge vermehrter Fluessigkeitsabgabe durch Durchfaelle und Erbrechen oder infolge Plasmauebertritt ins Gewebe (protoplasmatischer Kollaps):

Ausgedehnte guenstige Erfolge wurden erzielt mit der Periston-Behandlung der Exsiccosen der Paediatrie, ferner auch der Kreislaufschaeden im Verlauf von Brechdurchfaellen Erwachsener (Ruhr, Cholera).

Nachdem sich Periston bei Verbrennungen bereits hervorragend bewaehrte, stellen die analogen Kreislaufschaeden durch Plasmauebertritt ins Gewebe infolge Kapillarwandschaedigung bei Infektionskrankheiten, wie z.B. Sepsis, Diphtherie, Pneumonie, Fleckfieber und andere, Indikationen zur Periston-Anwendung dar.

Auch bei Kreislaufschaeden bei Erfrierungen, die denen bei Verbrennungen entsprechen, wurden guenstige Erfahrungen gemacht. Ist bei exsiccotischen Zustaenden neben der Kreislaufauffuellung eine Befeuchtung der Gewebe erforderlich, so empfehlen sich subkutan oder rektal verabfolgte kolloidfreie Salz- und Zuckerloesungen.

Anwendung und Dosierung

Obwohl Periston von jedem Gewebe vertragen wird, ist es seinem Wesen entsprechend nur intravenoes anzuwenden. Bei anderweitiger Verabreichungsart kann der beabsichtigte Erfolg nicht eintreten.

(a) Erwachsene. Die durchschnittliche Dosis beim Erwachsenen betraegt 500 ccm. Je nach Lage des Falles koennen kleinere oder groessere Mengen angezeigt sein.

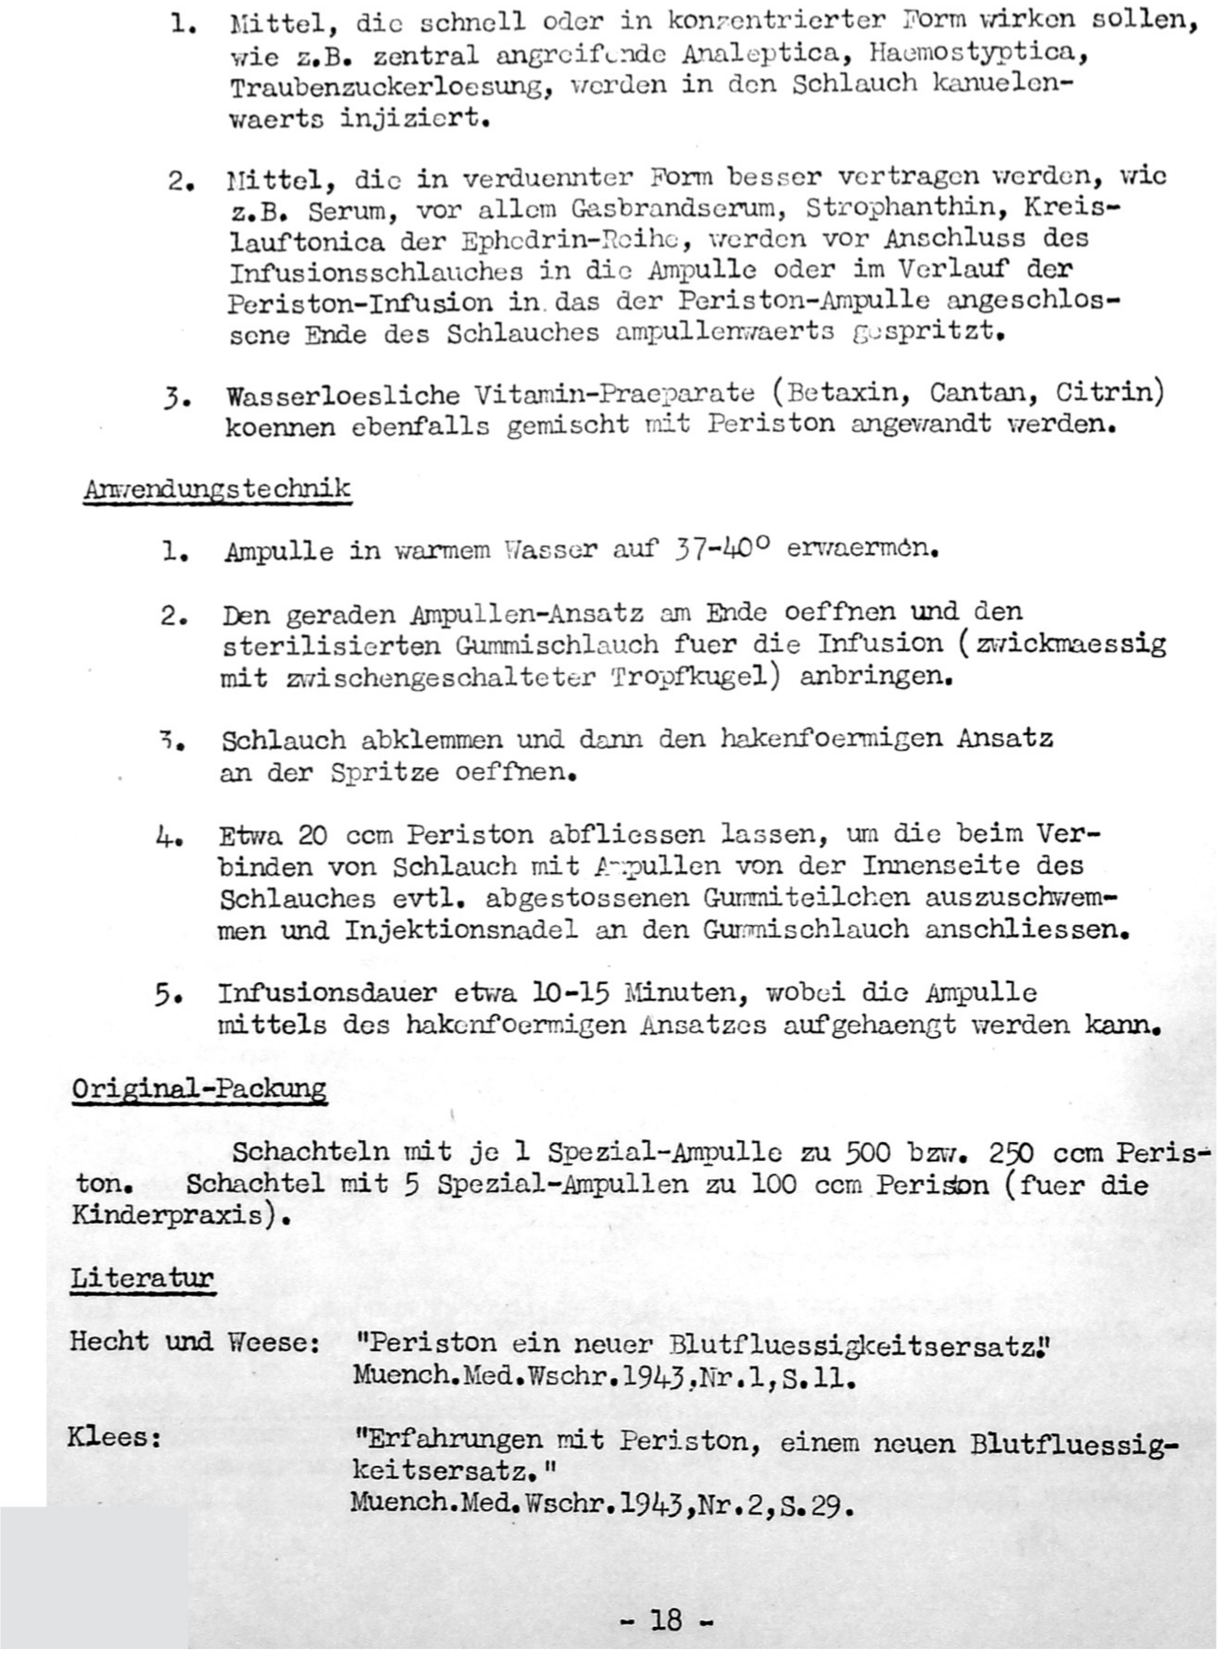
(b) Kinder. Bei Exsiccosen (Toxikosen) hat sich die Dosis von 25 ccm Periston je kg Koerpergewicht, evtl. zweimal taeglich, als zweckmaessig erwiesen.

Die Infusion des auf Koerpertemperatur erwaermten Periston soll langsam in 10-15 Minuten intravenoes erfolgen. Gegebenenfalls kann es auch als Tropfinfusion verabreicht werden.

Die Infusion kann nach Bedarf wiederholt werden. Periston ist kein Allergen, Vorsichtsmassnahmen in dieser Hinsicht eruebrigen sich.

Gleichzeitig erwuenschte injizierbare wasserloesliche Medikamente lassen sich zusammen mit Periston, das bei der Reaktionstraegheit des Polyvinylpyrrolidons keine chemischen Umsetzungen verursacht, in folgender Weise anwenden:

Figure A.29: A report on periston synthetic blood plasma [BIOS 354].



1. Mittel, die schnell oder in konzentrierter Form wirken sollen, wie z.B. zentral angreifende Analeptica, Haemostyptica, Traubenzuckerloesung, werden in den Schlauch kanuelenwaerts injiziert.

2. Mittel, die in verduennter Form besser vertragen werden, wie z.B. Serum, vor allem Gasbrandserum, Strophanthin, Kreislauftonica der Ephedrin-Reihe, werden vor Anschluss des Infusionsschlauches in die Ampulle oder im Verlauf der Periston-Infusion in das der Periston-Ampulle angeschlossene Ende des Schlauches ampullenwaerts gespritzt.

3. Wasserloesliche Vitamin-Praeparate (Betaxin, Cantan, Citrin) koennen ebenfalls gemischt mit Periston angewandt werden.

Anwendungstechnik

1. Ampulle in warmem Wasser auf 37-40° erwaermen.

2. Den geraden Ampullen-Ansatz am Ende oeffnen und den sterilisierten Gummischlauch fuer die Infusion (zwickmaessig mit zwischengeschalteter Tropfkugel) anbringen.

3. Schlauch abklemmen und dann den hakenfoermigen Ansatz an der Spritze oeffnen.

4. Etwa 20 ccm Periston abfliessen lassen, um die beim Verbinden von Schlauch mit Ampullen von der Innenseite des Schlauches evtl. abgestossenen Gummiteilchen auszuschwemmen und Injektionsnadel an den Gummischlauch anschliessen.

5. Infusionsdauer etwa 10-15 Minuten, wobei die Ampulle mittels des hakenfoermigen Ansatzes aufgehaengt werden kann.

Original-Packung

Schachteln mit je 1 Spezial-Ampulle zu 500 bzw. 250 ccm Periston. Schachtel mit 5 Spezial-Ampullen zu 100 ccm Periston (fuer die Kinderpraxis).

BIOS 395. *German Fluorescent Lamp Industry and Phosphor Chemical Manufacture.* pp. 1–2

Dr. Leonhard Birkofor was assistant to Prof. Richard Kuhn described as Director of the Institute for Chemistry and Administrative Head of the Kaiser Wilhelm Institute.

[...] Dr. Leonhard Birkofor was interviewed during the period the investigating team was awaiting Dr. Leibnitz. He volunteered the information that the work of Dr. Kuhn and himself was directed largely to biological and biochemical research. He stated that they had developed a substituted benzil compound of the following constitution:-

i.e., symmetrical 1.1. dihydroxy 4.4 dibrom benzil, which he stated had bacteriocidal properties similar to those of penicillin. The compound MP 213^{o}C consisted of yellow needles and a 5 gm. sample was obtained.

Dr. Birkofor stated that so far 500 gms. had been distributed and tests in various hospitals had shown positive reactions against streptococcus, staphylococcus, gonococcus and pneumococcus. The medical investigations at these hospitals were continuing.

BIOS 436. ***Enzyme Products and "Acrisin" Finishing Agents for Textiles: Rohm and Haas G.m.b.H., Darmstadt.*** [Enzymes for washing]

[...] Concentrated preparations of pancreatic tryptase and diastase were prepared from an aqueous extract by selective precipitation. The concentrated products were diluted with sodium carbonate or sodium chloride respectively before being sold. [...]

No research had been carried out recently on enzyme products although the production of bacterial enzymes had been considered. [...]

The rough powder is ground and laboratory tests are carried out to estimate the enzymatic activity. The products are diluted, if necessary, in order that the final mixture will meet the standard specification for rate of conversion of starch to sugar (diastase) or for rate of liquefaction of gelatine (tryptase).

Care was necessary in handling the concentrated tryptase preparation in view of its rapid attack of animal tissue. Gloves, goggles and dust masks were provided for the workers but it had not always been possible to compel workers to wear them.

These highly concentrated works products are diluted between 40 and 50 times before being marketed. The principle diluent for the diastase is sodium chloride and for tryptase, sodium carbonate with or without sodium sulphate. With the diastase preparation, however, 5% calcium formate and mono- and di-sodium phosphates are added. The calcium formate is used to avoid the effect of varying hardness of different waters and the phosphates buffer solutions of the product to pH 6.6 to 7. The diastase is marketed under the name "Degomma" for desizing cotton fabrics.

The tryptase products were used on a considerable scale for bating and de-hairing hides but a very large mount was used for soaking articles before washing.

In the soaking powder, the concentrated tryptase is diluted with approximately 98% sodium carbonate, and the product is called Burnus or Enzymolin. A ½% solution is used at 35^{o}C (not exceeding 40 ^{o}C) for 10–15 minutes in commercial laundries whilst for household use an overnight soak is given in a similar solution.

It is claimed that much of the soiling matter is attached to fabrics by means of protein, starch or fatty matter and that these cementing materials are attacked and rendered soluble by the enzymes thus simplifying the subsequent washing process.

The maximum production of Burnus has been about 170 metric tons per month.

[pp. 2–12:]

Report on the Researches of the Scientific Laboratory of C. F. Boehringer & Soehne, Mannheim-Waldhof during the war 1939–1945

[...] The research on producing the thymus hormone was based on the studies of Bomskov, who ascertained that extracts of the thymus glands of guinea-pigs are able to mobilize glycogen stored in different organs such as heart, liver and muscles. [...] He found, that the thymus really is a gland of internal secretion. Tests were made to concentrate the active substance and to establish its constitution. Bomskov made acetone extracts and showed that the active substance, especially after saponifying can be extracted with ether. We used glacial acetic acid and hydrocarbon chlorides as extracting solvents, the latter proved especially advantageous, as shown by the following examples[...]

Together with Prof. Brederick we elaborate a procedure for the manufacture of caffeine from uric acid. The uric acid is to be added in a formamide-melt of about 200^o and so transformed to xanthine, which is easily converted to caffeine by methylating with dimethylsulphate [...]

The greatest obstacle in this process is to procure a sufficiently pure and cheap uric acid.

The process with serpents' excrement which contains more than 80% of uric acid, is very easy and needs no further purification. [...]

Manufacture of Malaria Remedies.

[...] The new compound designated "Amichin" is scarcely inferior to quinine, whilst in general variations in the quinine molecule result in diminishing the anti-malaria efficiency. Many azo-compounds of Amichin were prepare and tested. Of these "Amichinazokairolin" proved especially non toxic and about 30 times more active than quinine in the canary test. This exceedingly favourable result caused us to test this product on man in larger scale. [...] There it proved that the strong increase of efficiency shown in the canary test was not so marked in human experiments, whilst the good tolerableness was maintained. The augmentation of efficiency compared to quinine amounted to only about four fold in the same range of application (that is both compounds act against schizontes only and not against gametes). [...]

In general the yeast was subject to an exact investigation. We are manufacturing on a factory scale nucleic acid from yeast and the resulting protein products were worked up to an animal food. As in wartime there is a large deficit in protein, we tried to transform the protein by-products of the nucleic acid manufacture into products fit for human nourishment. We succeeded in extracting albumen which can be whipped and which could replace the albumen in cooking and baking. This chemical introduced in trade circles under the trade mark "Backalbin" was sold in many thousands of kilos until the shortage of yeast stopped the manufacture. [...]

Furthermore we were producing a preparation of capsaicin to replace pepper. [...]

Figure A.32: BIOS 449 described the industrial farming of uric acid from snake urine and the conversion of the uric acid into caffeine.

[pp. 21–23]

Schering A.G., Berlin N 65 Werk Müllerstr. 170/72 [...]

Penicillin This had been mainly on a laboratory scale. The strain they had used was supplied by Prof. Rostock. It was suggested that he might have obtained it from Jena or perhaps Hanover. The unitage they obtained was 5–20 units/c.c. on the 13th and 14th days on a Czapek Dox medium with added lactose or glucose. Even though this was said to have been on a laboratory scale we found that the autoclave they had used was said to weigh 18 tons. The standard used was captured English penicillin and they used the inhibition of growth of Staph. aureus in 50 c.c. of medium. They had supplied some clinics in Berlin and Leipzig with material for trial but there had been little available for the chemical determination of the constitution of penicillin. (We think that this statement is not quite accurate but Dr. Clerc himself was not involved in the various procedures described.)

[p. 37]

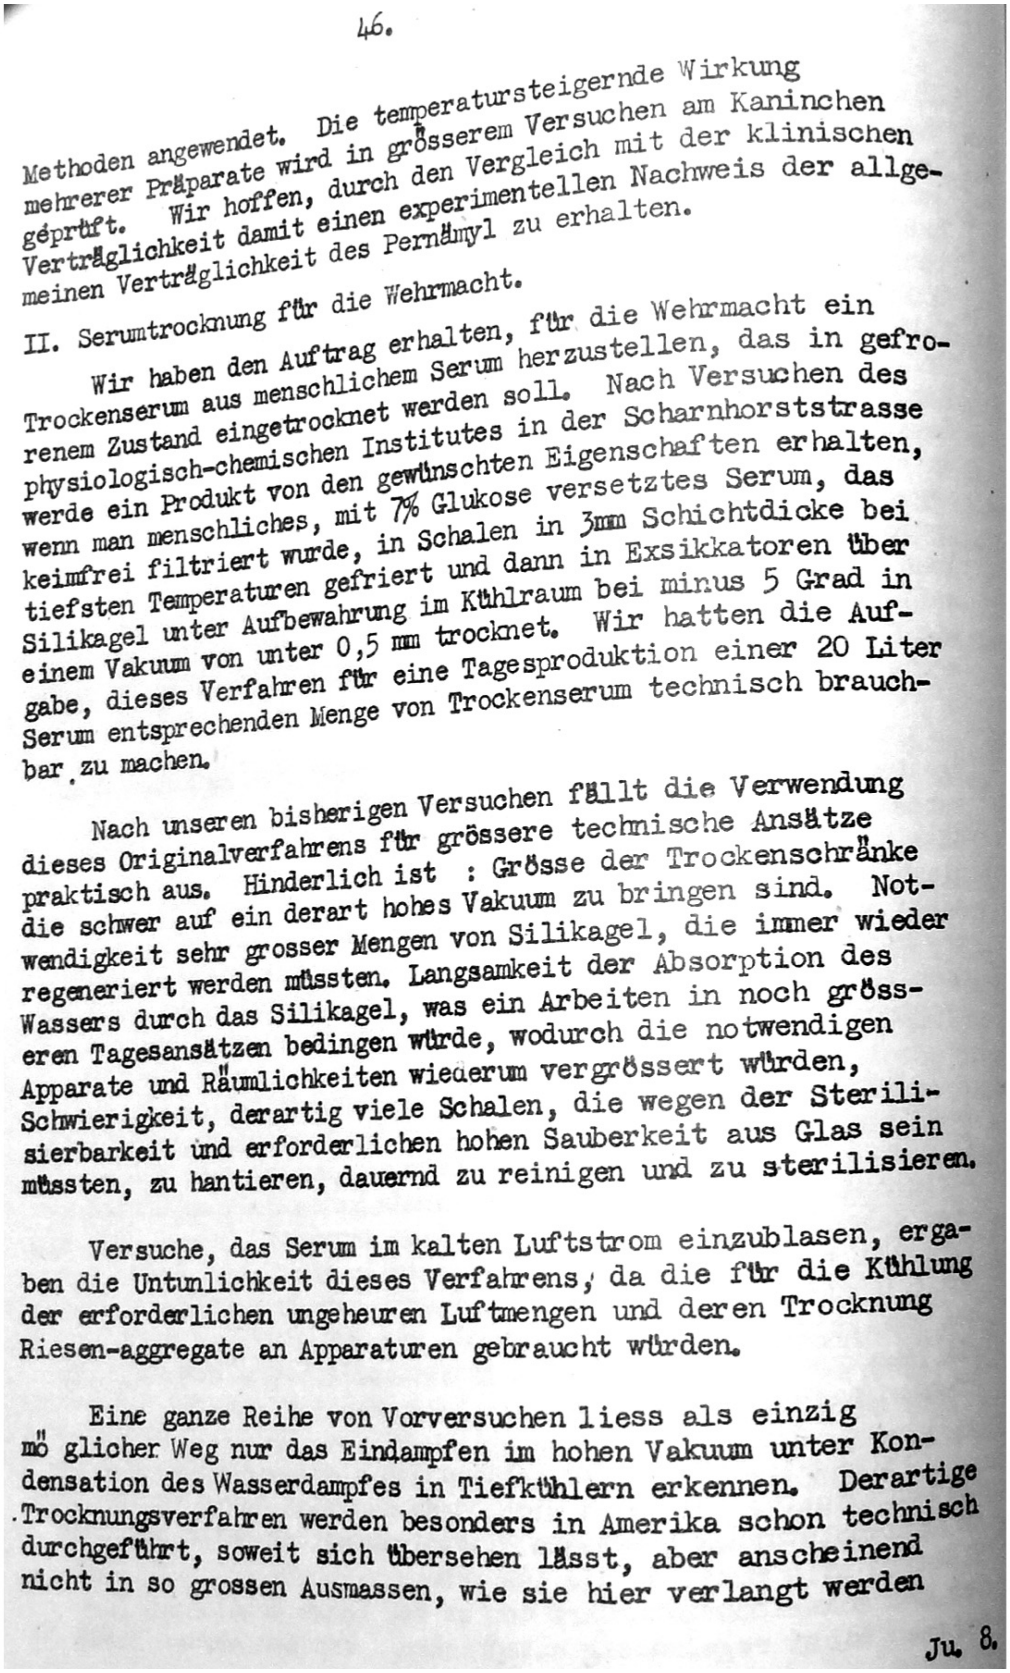
EXPERIMENTAL TUMOURS

Various experiments to uncover possible immunity mechanisms were carried out (e.g., immune sera (anti-Ehrlich carcinoma sera in rabbits, etc.) and attempts to breed tumour immune animals). The Ehrlich ascites tumour was fractioned and of the various portions used as antigens the mitochondrial fraction showed the most interesting results. The work ultimately had to be confined within very narrow limits.

DRYING OF SERUM FOR THE WEHRMACHT

Work on the freeze drying of human serum started early in 1941. They were alive to the possibilities for the use of this process not only for war purposes but also for various processes and products required in peace. They devised an apparatus capable of drying some 20 litres a day by the beginning of 1942. Finally in the first six months of 1943 they prepared 348 kg of dried serum and in 1944 607 kg. They planned to have a special serum drying plant at Luckenwalde. In the first three months of 1945 their output of dried serum dropped some 70%. The Military Medical Academy was interested in the amino acid content of blood hydrolysates for use in hunger oedema.

[Please see the following pages for more information from this report on producing freeze-dried human blood, therapeutic antibodies that target cancer cells, and other advanced medical therapeutics.]



Methoden angewendet. Die temperatursteigernde Wirkung mehrerer Präparate wird in grösserem Versuchen am Kaninchen geprüft. Wir hoffen, durch den Vergleich mit der klinischen Verträglichkeit damit einen experimentellen Nachweis der allgemeinen Verträglichkeit des Pernämyl zu erhalten.

II. Serumtrocknung für die Wehrmacht.

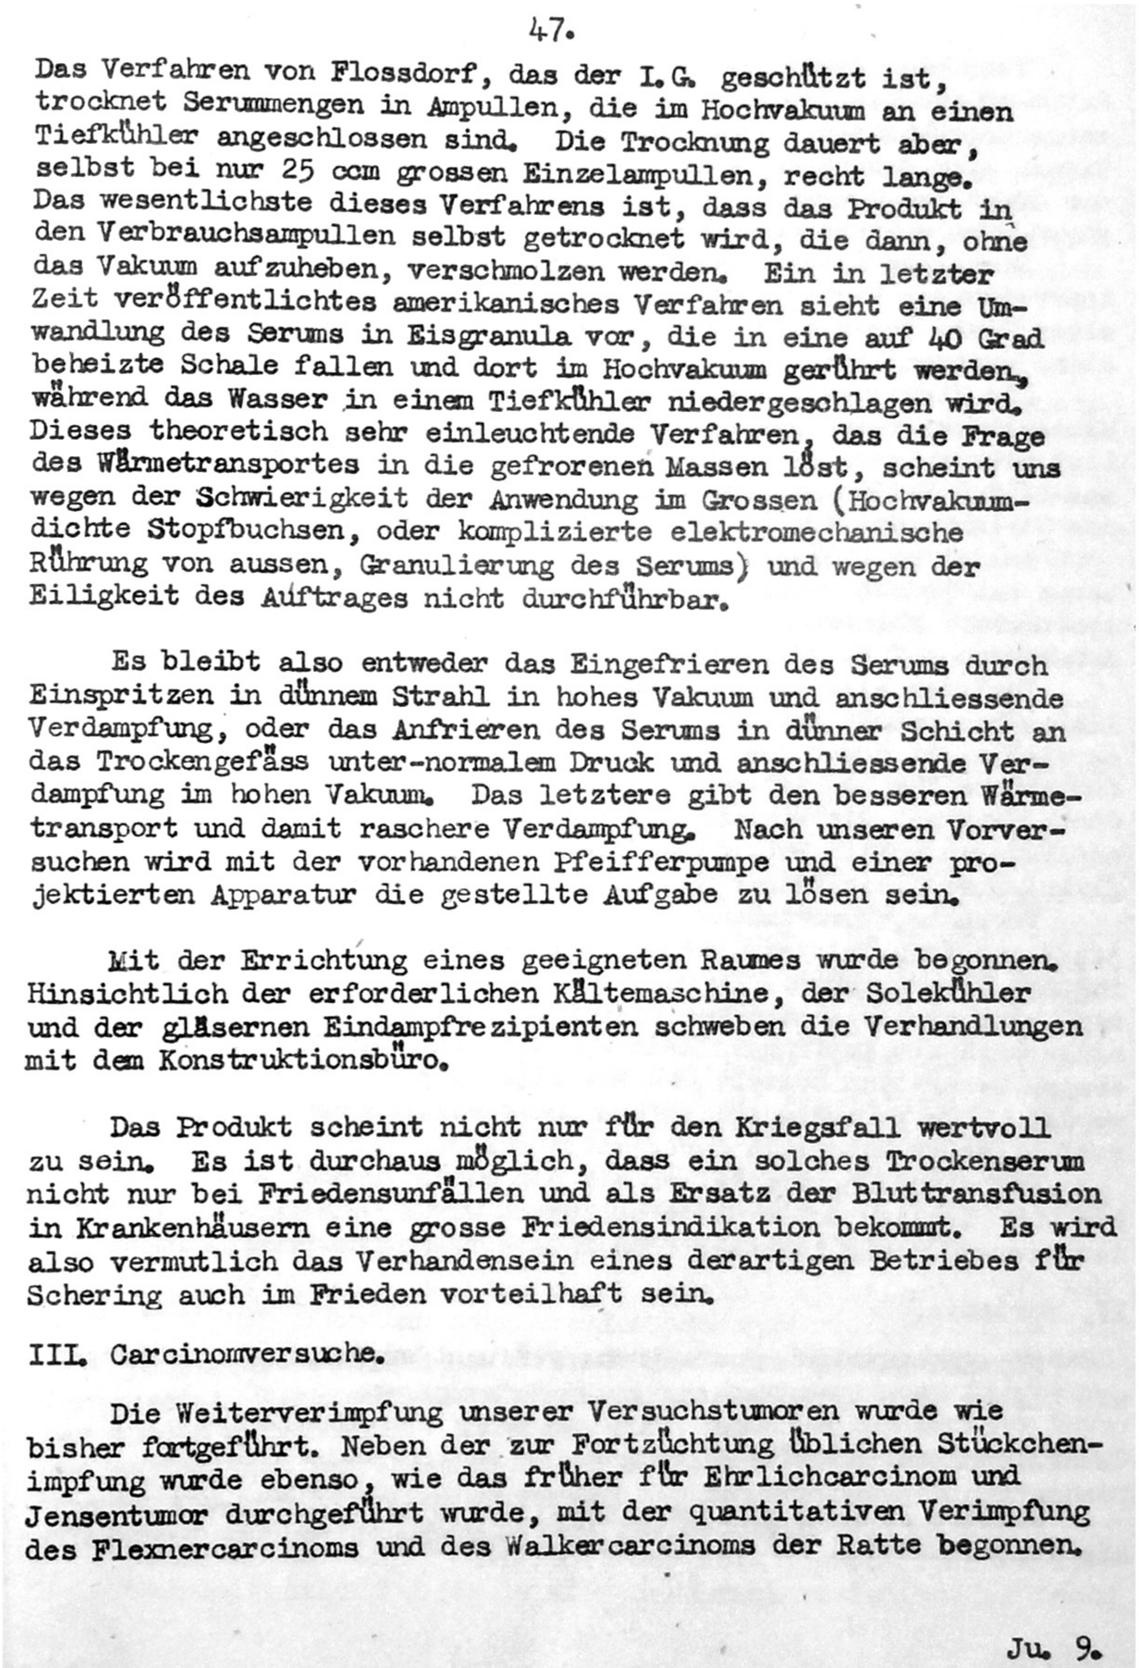
Wir haben den Auftrag erhalten, für die Wehrmacht ein Trockenserum aus menschlichem Serum herzustellen, das in gefrorenem Zustand eingetrocknet werden soll. Nach Versuchen des physiologisch-chemischen Institutes in der Scharnhorststrasse werde ein Produkt von den gewünschten Eigenschaften erhalten, wenn man menschliches, mit 7% Glukose versetztes Serum, das keimfrei filtriert wurde, in Schalen in 3mm Schichtdicke bei tiefsten Temperaturen gefriert und dann in Exsikkatoren über Silikagel unter Aufbewahrung im Kühlraum bei minus 5 Grad in einem Vakuum von unter 0,5 mm trocknet. Wir hatten die Aufgabe, dieses Verfahren für eine Tagesproduktion einer 20 Liter Serum entsprechenden Menge von Trockenserum technisch brauchbar zu machen.

Nach unseren bisherigen Versuchen fällt die Verwendung dieses Originalverfahrens für grössere technische Ansätze praktisch aus. Hinderlich ist : Grösse der Trockenschränke die schwer auf ein derart hohes Vakuum zu bringen sind. Notwendigkeit sehr grosser Mengen von Silikagel, die immer wieder regeneriert werden müssten. Langsamkeit der Absorption des Wassers durch das Silikagel, was ein Arbeiten in noch grösseren Tagesansätzen bedingen würde, wodurch die notwendigen Apparate und Räumlichkeiten wiederum vergrössert würden, Schwierigkeit, derartig viele Schalen, die wegen der Sterilisierbarkeit und erforderlichen hohen Sauberkeit aus Glas sein müssten, zu hantieren, dauernd zu reinigen und zu sterilisieren.

Versuche, das Serum im kalten Luftstrom einzublasen, ergaben die Untunlichkeit dieses Verfahrens, da die für die Kühlung der erforderlichen ungeheuren Luftmengen und deren Trocknung Riesen-aggregate an Apparaturen gebraucht würden.

Eine ganze Reihe von Vorversuchen liess als einzig möglicher Weg nur das Eindampfen im hohen Vakuum unter Kondensation des Wasserdampfes in Tiefkühlern erkennen. Derartige Trocknungsverfahren werden besonders in Amerika schon technisch durchgeführt, soweit sich übersehen lässt, aber anscheinend nicht in so grossen Ausmassen, wie sie hier verlangt werden

Figure A.33: A report on producing freeze-dried human blood, therapeutic antibodies that target cancer cells, and other advanced medical therapeutics [BIOS 449].



47.

Das Verfahren von Flossdorf, das der I.G. geschützt ist, trocknet Serummengen in Ampullen, die im Hochvakuum an einen Tiefkühler angeschlossen sind. Die Trocknung dauert aber, selbst bei nur 25 ccm grossen Einzelampullen, recht lange. Das wesentlichste dieses Verfahrens ist, dass das Produkt in den Verbrauchsampullen selbst getrocknet wird, die dann, ohne das Vakuum aufzuheben, verschmolzen werden. Ein in letzter Zeit veröffentlichtes amerikanisches Verfahren sieht eine Umwandlung des Serums in Eisgranula vor, die in eine auf 40 Grad beheizte Schale fallen und dort im Hochvakuum gerührt werden, während das Wasser in einem Tiefkühler niedergeschlagen wird. Dieses theoretisch sehr einleuchtende Verfahren, das die Frage des Wärmetransportes in die gefrorenen Massen löst, scheint uns wegen der Schwierigkeit der Anwendung im Grossen (Hochvakuumdichte Stopfbuchsen, oder komplizierte elektromechanische Rührung von aussen, Granulierung des Serums) und wegen der Eiligkeit des Auftrages nicht durchführbar.

Es bleibt also entweder das Eingefrieren des Serums durch Einspritzen in dünnem Strahl in hohes Vakuum und anschliessende Verdampfung, oder das Anfrieren des Serums in dünner Schicht an das Trockengefäss unter-normalem Druck und anschliessende Verdampfung im hohen Vakuum. Das letztere gibt den besseren Wärmetransport und damit raschere Verdampfung. Nach unseren Vorversuchen wird mit der vorhandenen Pfeifferpumpe und einer projektierten Apparatur die gestellte Aufgabe zu lösen sein.

Mit der Errichtung eines geeigneten Raumes wurde begonnen. Hinsichtlich der erforderlichen Kältemaschine, der Solekühler und der gläsernen Eindampfrezipienten schweben die Verhandlungen mit dem Konstruktionsbüro.

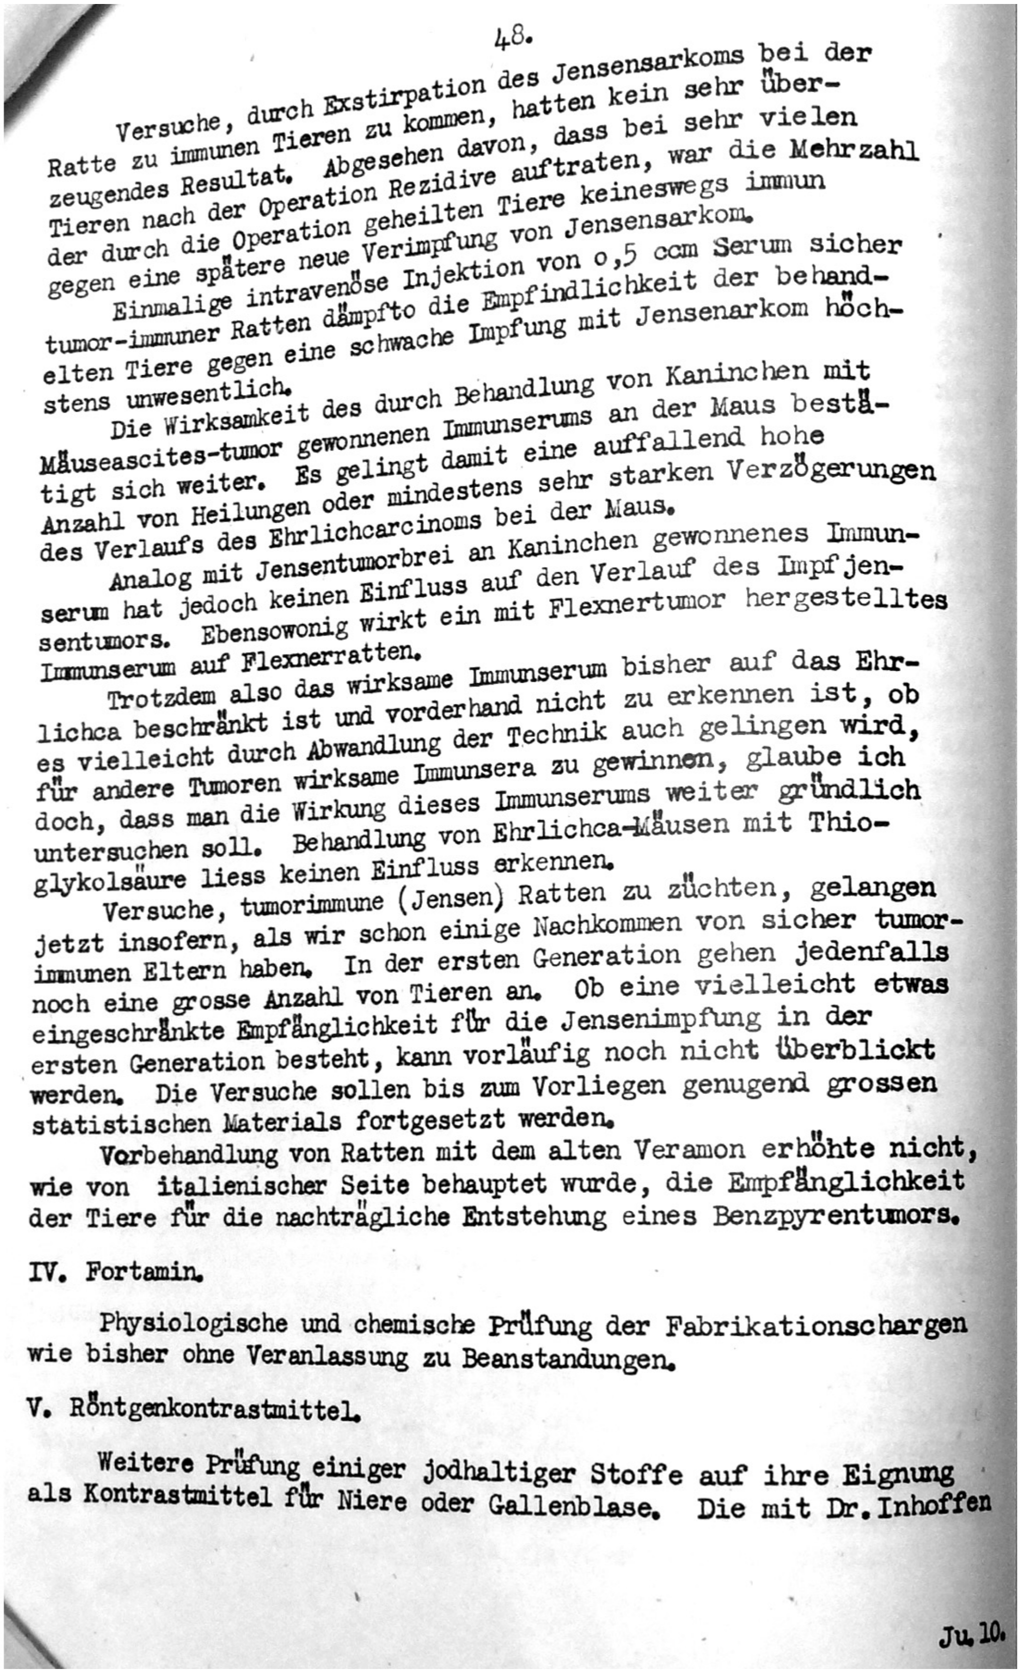
Das Produkt scheint nicht nur für den Kriegsfall wertvoll zu sein. Es ist durchaus möglich, dass ein solches Trockenserum nicht nur bei Friedensunfällen und als Ersatz der Bluttransfusion in Krankenhäusern eine grosse Friedensindikation bekommt. Es wird also vermutlich das Verhandensein eines derartigen Betriebes für Schering auch im Frieden vorteilhaft sein.

III. Carcinomversuche.

Die Weiterverimpfung unserer Versuchstumoren wurde wie bisher fortgeführt. Neben der zur Fortzüchtung üblichen Stückchenimpfung wurde ebenso, wie das früher für Ehrlichcarcinom und Jensentumor durchgeführt wurde, mit der quantitativen Verimpfung des Flexnercarcinoms und des Walkercarcinoms der Ratte begonnen.

Ju. 9.

Figure A.34: A report on producing freeze-dried human blood, therapeutic antibodies that target cancer cells, and other advanced medical therapeutics [BIOS 449].



48.

Versuche, durch Exstirpation des Jensensarkoms bei der Ratte zu immunen Tieren zu kommen, hatten kein sehr überzeugendes Resultat. Abgesehen davon, dass bei sehr vielen Tieren nach der Operation Rezidive auftraten, war die Mehrzahl der durch die Operation geheilten Tiere keineswegs immun gegen eine spätere neue Verimpfung von Jensensarkom.

Einmalige intravenöse Injektion von o,5 ccm Serum sicher tumor-immuner Ratten dämpfto die Empfindlichkeit der behandelten Tiere gegen eine schwache Impfung mit Jensenarkom höchstens unwesentlich.

Die Wirksamkeit des durch Behandlung von Kaninchen mit Mäuseascites-tumor gewonnenen Immunserums an der Maus bestätigt sich weiter. Es gelingt damit eine auffallend hohe Anzahl von Heilungen oder mindestens sehr starken Verzögerungen des Verlaufs des Ehrlichcarcinoms bei der Maus.

Analog mit Jensentumorbrei an Kaninchen gewonnenes Immunserum hat jedoch keinen Einfluss auf den Verlauf des Impfjensentumors. Ebensowonig wirkt ein mit Flexnertumor hergestelltes Immunserum auf Flexnerratten.

Trotzdem also das wirksame Immunserum bisher auf das Ehrlichca beschränkt ist und vorderhand nicht zu erkennen ist, ob es vielleicht durch Abwandlung der Technik auch gelingen wird, für andere Tumoren wirksame Immunsera zu gewinnen, glaube ich doch, dass man die Wirkung dieses Immunserums weiter gründlich untersuchen soll. Behandlung von Ehrlichca-Mäusen mit Thioglykolsäure liess keinen Einfluss erkennen.

Versuche, tumorimmune (Jensen) Ratten zu züchten, gelangen jetzt insofern, als wir schon einige Nachkommen von sicher tumorimmunen Eltern haben. In der ersten Generation gehen jedenfalls noch eine grosse Anzahl von Tieren an. Ob eine vielleicht etwas eingeschränkte Empfänglichkeit für die Jensenimpfung in der ersten Generation besteht, kann vorläufig noch nicht überblickt werden. Die Versuche sollen bis zum Vorliegen genugend grossen statistischen Materials fortgesetzt werden.

Vorbehandlung von Ratten mit dem alten Veramon erhöhte nicht, wie von italienischer Seite behauptet wurde, die Empfänglichkeit der Tiere für die nachträgliche Entstehung eines Benzpyrentumors.

IV. Fortamin.

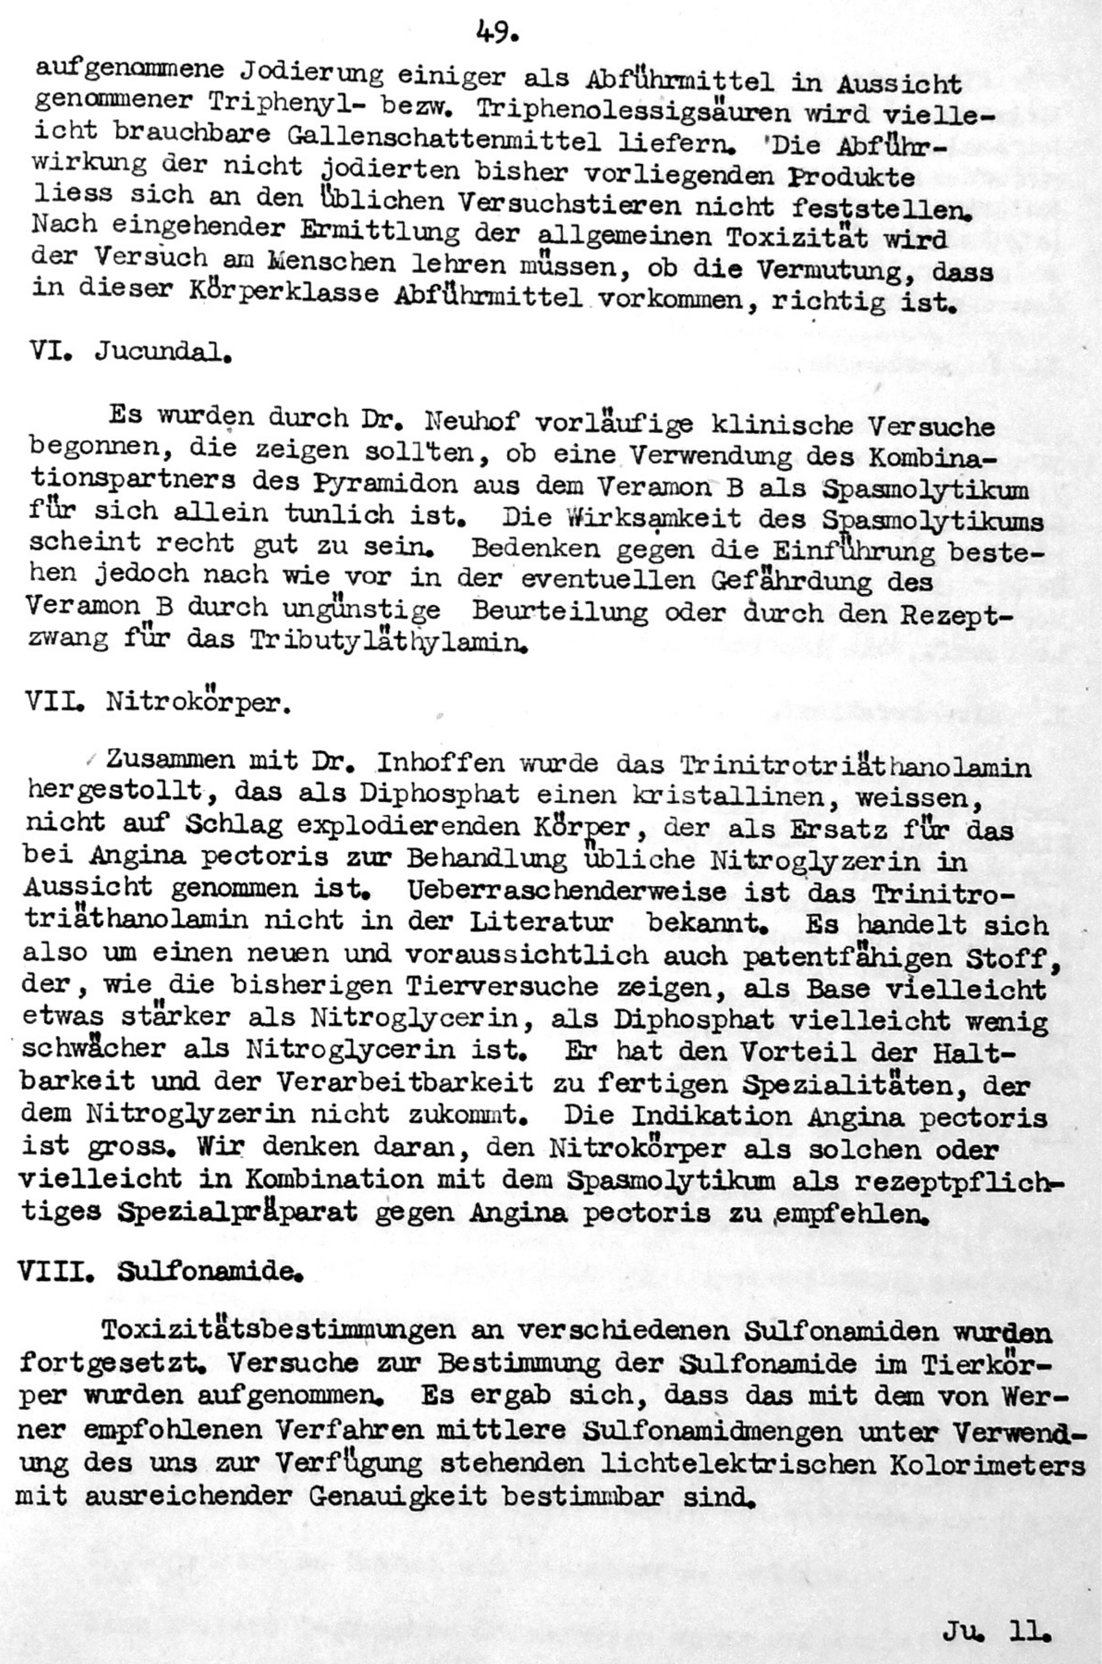
Physiologische und chemische Prüfung der Fabrikationschargen wie bisher ohne Veranlassung zu Beanstandungen.

V. Röntgenkontrastmittel.

Weitere Prüfung einiger jodhaltiger Stoffe auf ihre Eignung als Kontrastmittel für Niere oder Gallenblase. Die mit Dr. Inhoffen

Ju. 10.

Figure A.35: A report on producing freeze-dried human blood, therapeutic antibodies that target cancer cells, and other advanced medical therapeutics [BIOS 449].



49.

aufgenommene Jodierung einiger als Abführmittel in Aussicht genommener Triphenyl- bezw. Triphenolessigsäuren wird vielleicht brauchbare Gallenschattenmittel liefern. 'Die Abführwirkung der nicht jodierten bisher vorliegenden Produkte liess sich an den üblichen Versuchstieren nicht feststellen. Nach eingehender Ermittlung der allgemeinen Toxizität wird der Versuch am Menschen lehren müssen, ob die Vermutung, dass in dieser Körperklasse Abführmittel vorkommen, richtig ist.

VI. Jucundal.

Es wurden durch Dr. Neuhof vorläufige klinische Versuche begonnen, die zeigen sollten, ob eine Verwendung des Kombinationspartners des Pyramidon aus dem Veramon B als Spasmolytikum für sich allein tunlich ist. Die Wirksamkeit des Spasmolytikums scheint recht gut zu sein. Bedenken gegen die Einführung bestehen jedoch nach wie vor in der eventuellen Gefährdung des Veramon B durch ungünstige Beurteilung oder durch den Rezeptzwang für das Tributyläthylamin.

VII. Nitrokörper.

Zusammen mit Dr. Inhoffen wurde das Trinitrotriäthanolamin hergestollt, das als Diphosphat einen kristallinen, weissen, nicht auf Schlag explodierenden Körper, der als Ersatz für das bei Angina pectoris zur Behandlung übliche Nitroglyzerin in Aussicht genommen ist. Ueberraschenderweise ist das Trinitrotriäthanolamin nicht in der Literatur bekannt. Es handelt sich also um einen neuen und voraussichtlich auch patentfähigen Stoff, der, wie die bisherigen Tierversuche zeigen, als Base vielleicht etwas stärker als Nitroglycerin, als Diphosphat vielleicht wenig schwächer als Nitroglycerin ist. Er hat den Vorteil der Haltbarkeit und der Verarbeitbarkeit zu fertigen Spezialitäten, der dem Nitroglyzerin nicht zukommt. Die Indikation Angina pectoris ist gross. Wir denken daran, den Nitrokörper als solchen oder vielleicht in Kombination mit dem Spasmolytikum als rezeptpflichtiges Spezialpräparat gegen Angina pectoris zu empfehlen.

VIII. Sulfonamide.

Toxizitätsbestimmungen an verschiedenen Sulfonamiden wurden fortgesetzt. Versuche zur Bestimmung der Sulfonamide im Tierkörper wurden aufgenommen. Es ergab sich, dass das mit dem von Werner empfohlenen Verfahren mittlere Sulfonamidmengen unter Verwendung des uns zur Verfügung stehenden lichtelektrischen Kolorimeters mit ausreichender Genauigkeit bestimmbar sind.

BIOS 691. *Some Aspects of Microbiological Research in Germany.*

[pp. 1–2]

Professor Lembke, formerly director of the Bakteriologisches Institut, Preussische Versuchs- und Forschungsanstalt für Milchwirtschaft in Kiel, and now scientifically active again after a period of detention, was interviewed in Sielbeck to obtain a general picture of the work which had been carried out under his direction during the past six years. The Bakteriologisches Institut was totally destroyed by bombing during the war, but a good deal of work was carried on elsewhere, notably in Sielbeck at the temporary quarters of the Institut für Virusforschung of Kiel University. In the past few months new quarters for the Bakteriologisches Institut have been found in Kiel, and its work is gradually being reestablished there.

Professor Lembke and his associates have been active in a large number of fields, some of which have already been covered by previous reports (e.g. ultra-violet pasteurization of milk). However, two aspects of their investigations do not appear to have received detailed attention and seem worth study. These are (a) protein synthesis by yeasts and molds and (b) the production of antibiotics, notably of an alleged penicillin-like substance known as Mycoin C.

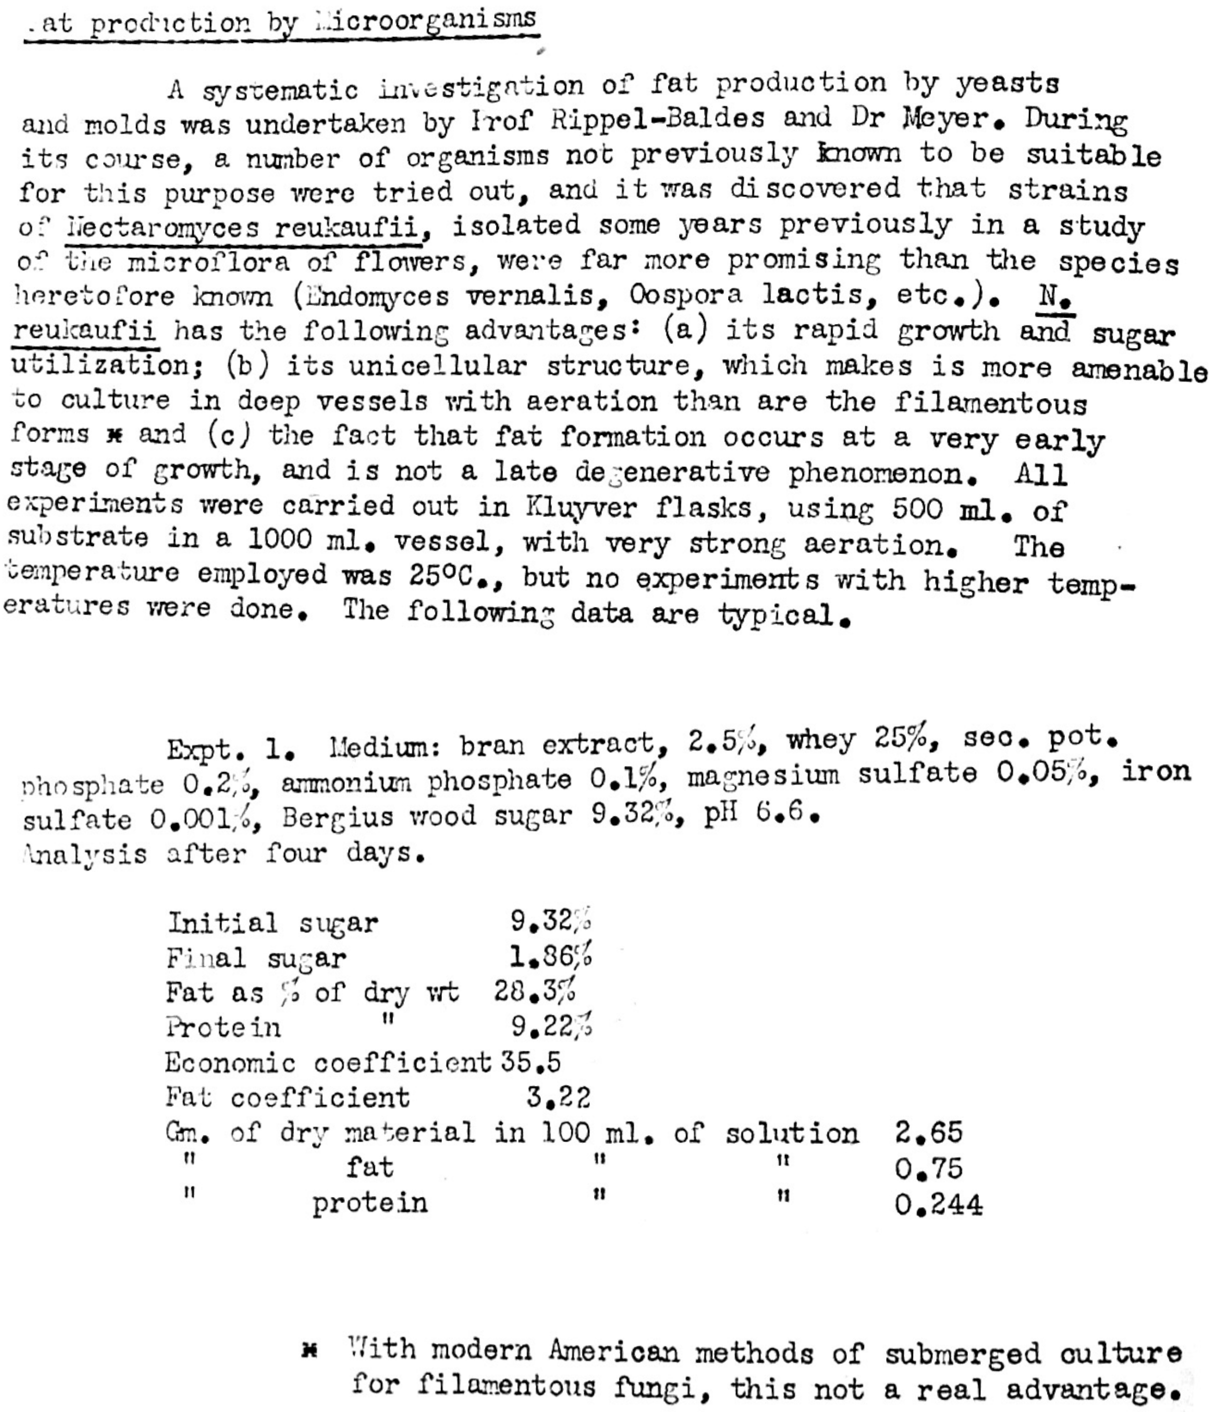
[...] The best organisms found for protein synthesis were Oospora lactis, Oospora amycelica, Saccharomyces lactis and Torulopsis sp.

[pp. 13–14]

A visit was also paid to Prof R. Harder at the Botanisches Institut. [...]

The basic concept underlying this approach to the problem of microbial fat production is a fairly obvious one. In the case of fat synthesis by non-photosynthetic microorganisms such as the yeasts, carbohydrates must be used as the raw material, and the process is highly wasteful from the overall standpoint, since a large part of the substrate is lost by respiration. Fat can undoubtedly be obtained, but only by using large amounts of carbohydrate otherwise utilizable as human or animal foodstuffs. On the other hand, if one could find good fat-producing photosynthetic microorganisms, fat could be obtained from them without any depletion of the carbohydrate supply.

Two good groups of fat-producing photosynthetic microorganisms were discovered: certain fresh-water diatoms, and strains of Chlamydomonas. [...] After various techniques of cultivation had been tried, the best proved to the use of tall glass cylinders, 5 cm in diameter and 80 cm high. They were filled almost completely with the culture medium and a slow current of air bubbled through during growth. [...] The algae grew luxuriantly and eventually underwent a “fatty degeneration”, the cells becoming packed with large fat globules. In the case of Chlamydomonas this occurred after 10–14 days’ growth. [...] With artificial illumination there is also the possibility of obtaining a crop in depth.



Fat production by Microorganisms

A systematic investigation of fat production by yeasts and molds was undertaken by Prof Rippel-Baldes and Dr Meyer. During its course, a number of organisms not previously known to be suitable for this purpose were tried out, and it was discovered that strains of Nectaromyces reukaufii, isolated some years previously in a study of the microflora of flowers, were far more promising than the species heretofore known (Endomyces vernalis, Oospora lactis, etc.). N. reukaufii has the following advantages: (a) its rapid growth and sugar utilization; (b) its unicellular structure, which makes is more amenable to culture in deep vessels with aeration than are the filamentous forms * and (c) the fact that fat formation occurs at a very early stage of growth, and is not a late degenerative phenomenon. All experiments were carried out in Kluyver flasks, using 500 ml. of substrate in a 1000 ml. vessel, with very strong aeration. The temperature employed was 25°C., but no experiments with higher temperatures were done. The following data are typical.

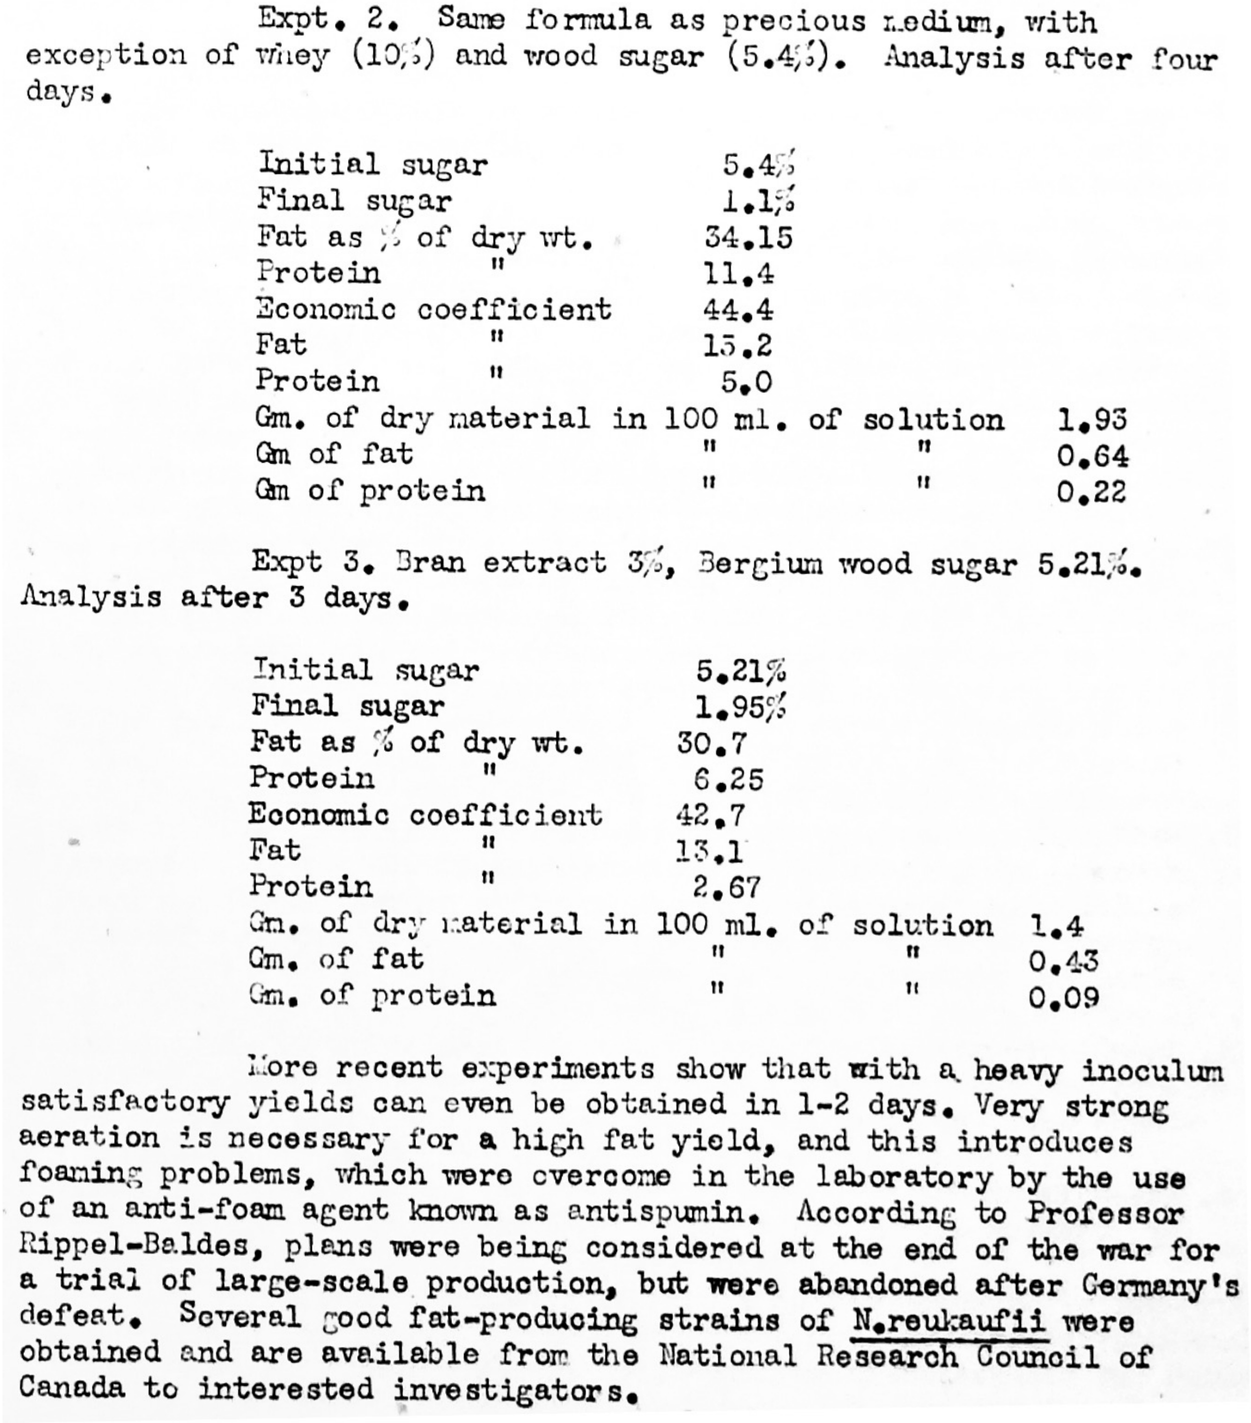
Expt. 1. Medium: bran extract, 2.5%, whey 25%, sec. pot. phosphate 0.2%, ammonium phosphate 0.1%, magnesium sulfate 0.05%, iron sulfate 0.001%, Bergius wood sugar 9.32%, pH 6.6.
Analysis after four days.

Initial sugar	9.32%
Final sugar	1.86%
Fat as % of dry wt	28.3%
Protein "	9.22%
Economic coefficient	35.5
Fat coefficient	3.22
Gm. of dry material in 100 ml. of solution	2.65
" fat " "	0.75
" protein " "	0.244

---

* With modern American methods of submerged culture for filamentous fungi, this not a real advantage.

Figure A.37: Fat production and extraction from yeast cultured in bioreactors [BIOS 691].



Expt. 2. Same formula as precious medium, with exception of whey (10%) and wood sugar (5.4%). Analysis after four days.

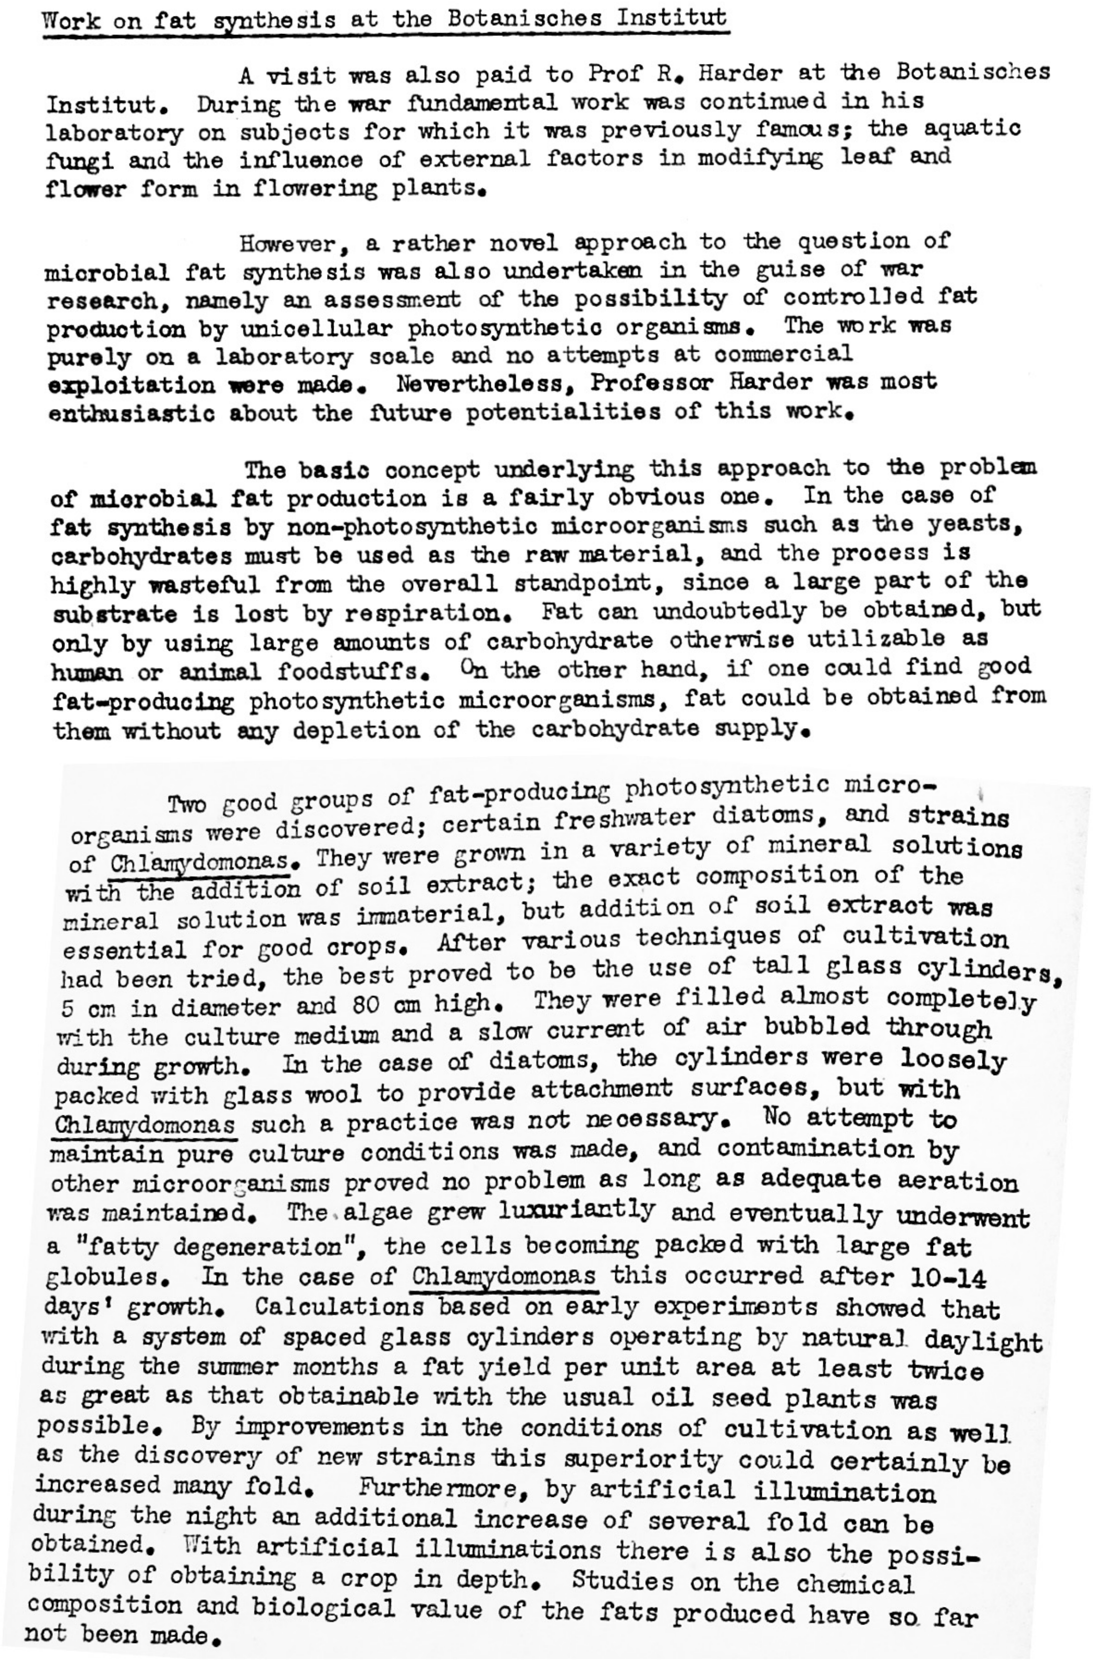
Initial sugar		5.4%	
Final sugar		1.1%	
Fat as % of dry wt.		34.15	
Protein	"	11.4	
Economic coefficient		44.4	
Fat	"	15.2	
Protein	"	5.0	
Gm. of dry material in 100 ml. of solution			1.93
Gm of fat	"	"	0.64
Gm of protein	"	"	0.22

Expt 3. Bran extract 3%, Bergium wood sugar 5.21%. Analysis after 3 days.

Initial sugar		5.21%	
Final sugar		1.95%	
Fat as % of dry wt.		30.7	
Protein	"	6.25	
Economic coefficient		42.7	
Fat	"	13.1	
Protein	"	2.67	
Gm. of dry material in 100 ml. of solution			1.4
Gm. of fat	"	"	0.43
Gm. of protein	"	"	0.09

More recent experiments show that with a heavy inoculum satisfactory yields can even be obtained in 1-2 days. Very strong aeration is necessary for a high fat yield, and this introduces foaming problems, which were overcome in the laboratory by the use of an anti-foam agent known as antispumin. According to Professor Rippel-Baldes, plans were being considered at the end of the war for a trial of large-scale production, but were abandoned after Germany's defeat. Several good fat-producing strains of N.reukaufii were obtained and are available from the National Research Council of Canada to interested investigators.

Figure A.38: Fat production and extraction from yeast cultured in bioreactors [BIOS 691].



Work on fat synthesis at the Botanisches Institut

A visit was also paid to Prof R. Harder at the Botanisches Institut. During the war fundamental work was continued in his laboratory on subjects for which it was previously famous; the aquatic fungi and the influence of external factors in modifying leaf and flower form in flowering plants.

However, a rather novel approach to the question of microbial fat synthesis was also undertaken in the guise of war research, namely an assessment of the possibility of controlled fat production by unicellular photosynthetic organisms. The work was purely on a laboratory scale and no attempts at commercial exploitation were made. Nevertheless, Professor Harder was most enthusiastic about the future potentialities of this work.

The basic concept underlying this approach to the problem of microbial fat production is a fairly obvious one. In the case of fat synthesis by non-photosynthetic microorganisms such as the yeasts, carbohydrates must be used as the raw material, and the process is highly wasteful from the overall standpoint, since a large part of the substrate is lost by respiration. Fat can undoubtedly be obtained, but only by using large amounts of carbohydrate otherwise utilizable as human or animal foodstuffs. On the other hand, if one could find good fat-producing photosynthetic microorganisms, fat could be obtained from them without any depletion of the carbohydrate supply.

Two good groups of fat-producing photosynthetic microorganisms were discovered; certain freshwater diatoms, and strains of Chlamydomonas. They were grown in a variety of mineral solutions with the addition of soil extract; the exact composition of the mineral solution was immaterial, but addition of soil extract was essential for good crops. After various techniques of cultivation had been tried, the best proved to be the use of tall glass cylinders, 5 cm in diameter and 80 cm high. They were filled almost completely with the culture medium and a slow current of air bubbled through during growth. In the case of diatoms, the cylinders were loosely packed with glass wool to provide attachment surfaces, but with Chlamydomonas such a practice was not necessary. No attempt to maintain pure culture conditions was made, and contamination by other microorganisms proved no problem as long as adequate aeration was maintained. The algae grew luxuriantly and eventually underwent a "fatty degeneration", the cells becoming packed with large fat globules. In the case of Chlamydomonas this occurred after 10-14 days' growth. Calculations based on early experiments showed that with a system of spaced glass cylinders operating by natural daylight during the summer months a fat yield per unit area at least twice as great as that obtainable with the usual oil seed plants was possible. By improvements in the conditions of cultivation as well as the discovery of new strains this superiority could certainly be increased many fold. Furthermore, by artificial illumination during the night an additional increase of several fold can be obtained. With artificial illuminations there is also the possibility of obtaining a crop in depth. Studies on the chemical composition and biological value of the fats produced have so far not been made.

Figure A.39: Fat production and extraction from algae cultured in bioreactors [BIOS 691].

BIOS 710. ***Manufacture of Biolase (Starch-Hydrolysing Enzyme) at Kalle & Co. (I. G. Farben A. G.) Wiesbaden, Biebrich.***

The manufacture of Biolase, a starch-hydrolysing enzyme, was carried out by Kalle & Co., Wiesbaden. A request has been made for details of their manufacturing process, and this report describes the information obtained as to the method used by Kalle & Co. as gained from an interrogation of a member of the staff, Dr. Altgelt. A brief description of the plant used is also given, but as this was not in operation when inspected in October 1945, it was not possible to check the statements made. [...]

The capacity of the plant was stated to be 30 tonnes per month, concentrated material, equivalent to 1350 tonnes per month of standard material.

In the building however, there were new plant items awaiting installation and the capacity of these was stated to be four times greater than that of the existing plant. Dr. Altgelt stated however, that the intention was to demolish the existing plant as soon as the new plant was in commission.

Einrichtung zur Behandlung von flüssigen Stoffen, insbesondere von Milch, mit UV-Strahlen

Patentiert im Gebiet der Bundesrepublik Deutschland vom 1. Februar 1940 an
Der Zeitraum vom 8. Mai 1945 bis einschließlich 7. Mai 1950 wird auf die Patentdauer nicht angerechnet
(Ges. v. 15. 7. 51)
Patentanmeldung bekanntgemacht am 26. Februar 1953
Patenterteilung bekanntgemacht am 17. September 1953

Die Erfindung betrifft eine Einrichtung zur Behandlung von Flüssigkeiten, insbesondere von Milch, mit UV-Strahlen. Das wesentlichste Kennzeichen der Erfindung besteht darin, daß sowohl die Strahlungsquellen für die UV-Strahlen als auch die Flüssigkeitsleitungen voneinander getrennt angeordnet sind.

Der Gegenstand der Erfindung weist die besonderen Vorteile auf, daß die einzelnen für die Behandlung wichtigen Teile, wie die UV-Lampen und die Rohrleitungen, unter sehr zweckmäßiger Ausnutzung vorhandener Räume leicht im Innern einer z. B. im Querschnitt runden Vorrichtung untergebracht werden können. Vor allem werden durch die voneinander getrennte Ausbildung der Strahlungsquellen und der Flüssigkeitsleitungen eine für manche Stoffe, insbesondere für Milch, schädliche Erwärmung weitgehend vermieden. Die neue Einrichtung gestattet, im gegebenen Fall die UV-Lampen hinreichend zu kühlen und ihre Anordnung in dem Behandlungsraum so zu treffen, daß das zu behandelnde Gut einer möglichst intensiven Beeinflussung durch die UV-Strahlen ausgesetzt ist. Auch die Auswechslung der Strahlenquellen und der Flüssigkeitsleitungen kann bei der neuen Einrichtung in besonders einfacher Weise vorgenommen werden. Die Verwendung der Apparatur im praktischen Betrieb bietet keinerlei

Anordnung zur Bestrahlung, insbesondere Ultraviolettbestrahlung, von Flüssigkeiten

Patentiert im Gebiet der Bundesrepublik Deutschland vom 6. Juni 1940 an
Der Zeitraum vom 8. Mai 1945 bis einschließlich 7. Mai 1950 wird auf die Patentdauer nicht angerechnet
(Ges. v. 15. 7. 51)
Patentanmeldung bekanntgemacht am 18. September 1952
Patenterteilung bekanntgemacht am 2. April 1953

Es sind Anordnungen zur Ultraviolettbestrahlung von Flüssigkeiten, beispielsweise Milch, bekannt, bei denen die Flüssigkeit ein Rohr aus Quarz oder einem anderen für Ultraviolettstrahlung durchlässigen Stoff durchläuft und von außen her der Einwirkung der Ultraviolettstrahlung ausgesetzt wird. Die bekannten Anordnungen haben aber alle den Nachteil, daß sich eine ausreichende Abtötung der in der Flüssigkeit, beispielsweise in Milch, befindlichen Mikroben, also der Bakterien und Pilze, nicht erreichen läßt, so daß keine genügend lange Haltbarkeit erzielt werden kann.

Eine besonders vorteilhafte Anordnung ist zur Bestrahlung, insbesondere Ultraviolettbestrahlung, von Flüssigkeiten vorgeschlagen worden, welche aus einer Mehrzahl von in einem Bestrahlungsbehälter zueinander parallel angeordneten strahlungsdurchlässigen Flüssigkeitsdurchflußrohren und stabförmigen Bestrahlungslampen besteht, wobei die Flüssigkeit alle Durchflußrohre oder eine Gruppe derselben nacheinander durchfließt. Diese Anordnung ist den bekannten Anordnungen dadurch überlegen, daß die Milch bzw. die Flüssigkeit den Bestrahlungsraum mehrmals nacheinander durchläuft und in den von den Bestrahlungslampen umgebenen Durchflußrohren besonders gut der Einwirkung der Ultraviolettstrahlung ausgesetzt ist und somit auch in erhöhtem Maße entkeimt wird.

Gegenstand der Erfindung ist eine Anordnung, welche allen bekannten Ultraviolettbestrahlungsein-

Verfahren zur Behandlung von Milch mit Ultraviolettstrahlen

Patentiert im Gebiet der Bundesrepublik Deutschland vom 27. Juli 1943 an
Der Zeitraum vom 8. Mai 1945 bis einschließlich 7. Mai 1950 wird auf die Patentdauer nicht angerechnet
(Ges. v. 15. 7. 51)
Patentanmeldung bekanntgemacht am 4. Dezember 1952
Patenterteilung bekanntgemacht am 25. Juni 1953

Es ist bekannt, Milch zum Zweck der Sterilisierung auf eine höhere Temperatur zu erhitzen und sie mehr oder weniger lange Zeit der Einwirkung der Wärme auszusetzen, d. h. zu pasteurisieren.

Es ist auch bekannt, Milch kalt zu entkeimen, und zwar dadurch, daß man sie der Einwirkung von ultravioletten Strahlen aussetzt. Sofern hierzu die angelieferte Milch unmittelbar verwendet wird, zeigt diese im allgemeinen eine Temperatur von etwa 0 bis 15° C.

Wird nun Milch dieser Art in geeigneten Vorrichtungen der Ultraviolettbestrahlung unterworfen, so treten Schwierigkeiten auf, die den Erfolg der Maßnahme außerordentlich behindern bzw. überhaupt in Frage stellen. So hat es sich z. B. gezeigt, daß bei der Bestrahlung von Milch bei vergleichsweise niedriger Temperatur auf den Flüssigkeitsleitungen, in denen die Milch während der Behandlung geführt wird und in denen die Einwirkung des ultravioletten Lichtes erfolgt, Kondensationserscheinungen, und zwar des in der Raumatmosphäre vorhandenen Wasserdampfes auftreten. Die normalerweise aus Quarzrohren bestehenden Leitungen beschlagen dadurch, was den Durchgang der ultravioletten Strahlen weitestgehend verkleinert bzw. überhaupt verhindert.

Es ist zwar denkbar und technisch ausführbar, Mittel vorzusehen, durch die eine mechanische Entfernung dieses Kondensationsbeschlages auf den Flüssigkeitsleitungen herbeigeführt werden kann.

Figure A.46: Andreas Lembke, Hellmuth Bayha, Karl Krammer, Eugen Sauter, and other scientists developed and successfully implemented methods of using intense ultraviolet light to sterilize liquids and other materials [German patent DE 885,954, filed in 1943].

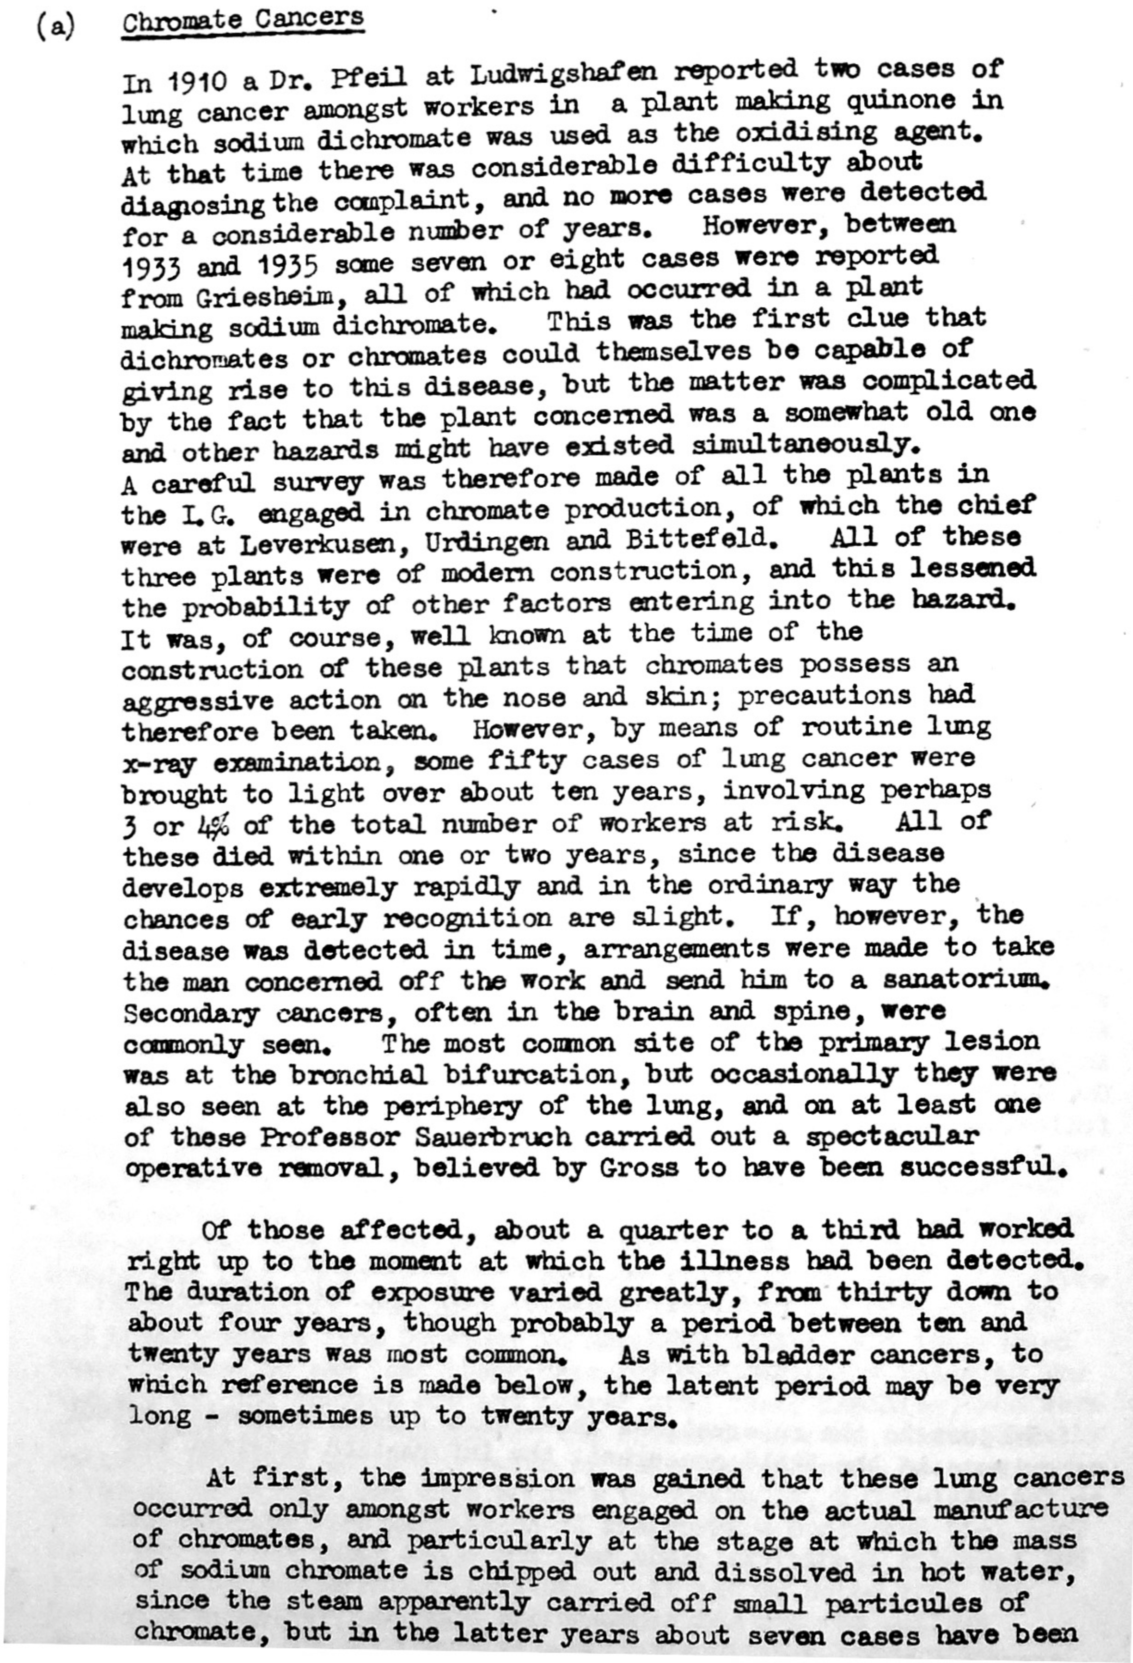
BIOS 1229. *Wool—Its Chemistry & Modification by Chemical Treatment in Germany.* pp. 6–7.

Schöberl has been interested in the chemistry and enzymatic activity of papain as well as its reaction on wool. In connection with the latter effect, the activation of papain by bodies containing mercapto and disulphide groups appears to be of interest. Natural, i.e., unpurified, papain contains its own activators in the form of mercapto bodies. Removal of these, results in a purified papain of increased sulphur content as sulphate and organically bound as cystine and to a less extent as methionine. Studying the activation of the purified papain on the liquefaction of gelatin, Schöberl observed that a mercaptan such as thioglycollic acid was a strong activator of papain and so also was the disulphide dithioglycollic acid. [...]

This work is described in a paper by Schöberl and Fisch ‘Über Schwefelgehalt und Aktivierbarkeit von Papain’—Biochemische Zeitschrift, 1939, 302, 310.



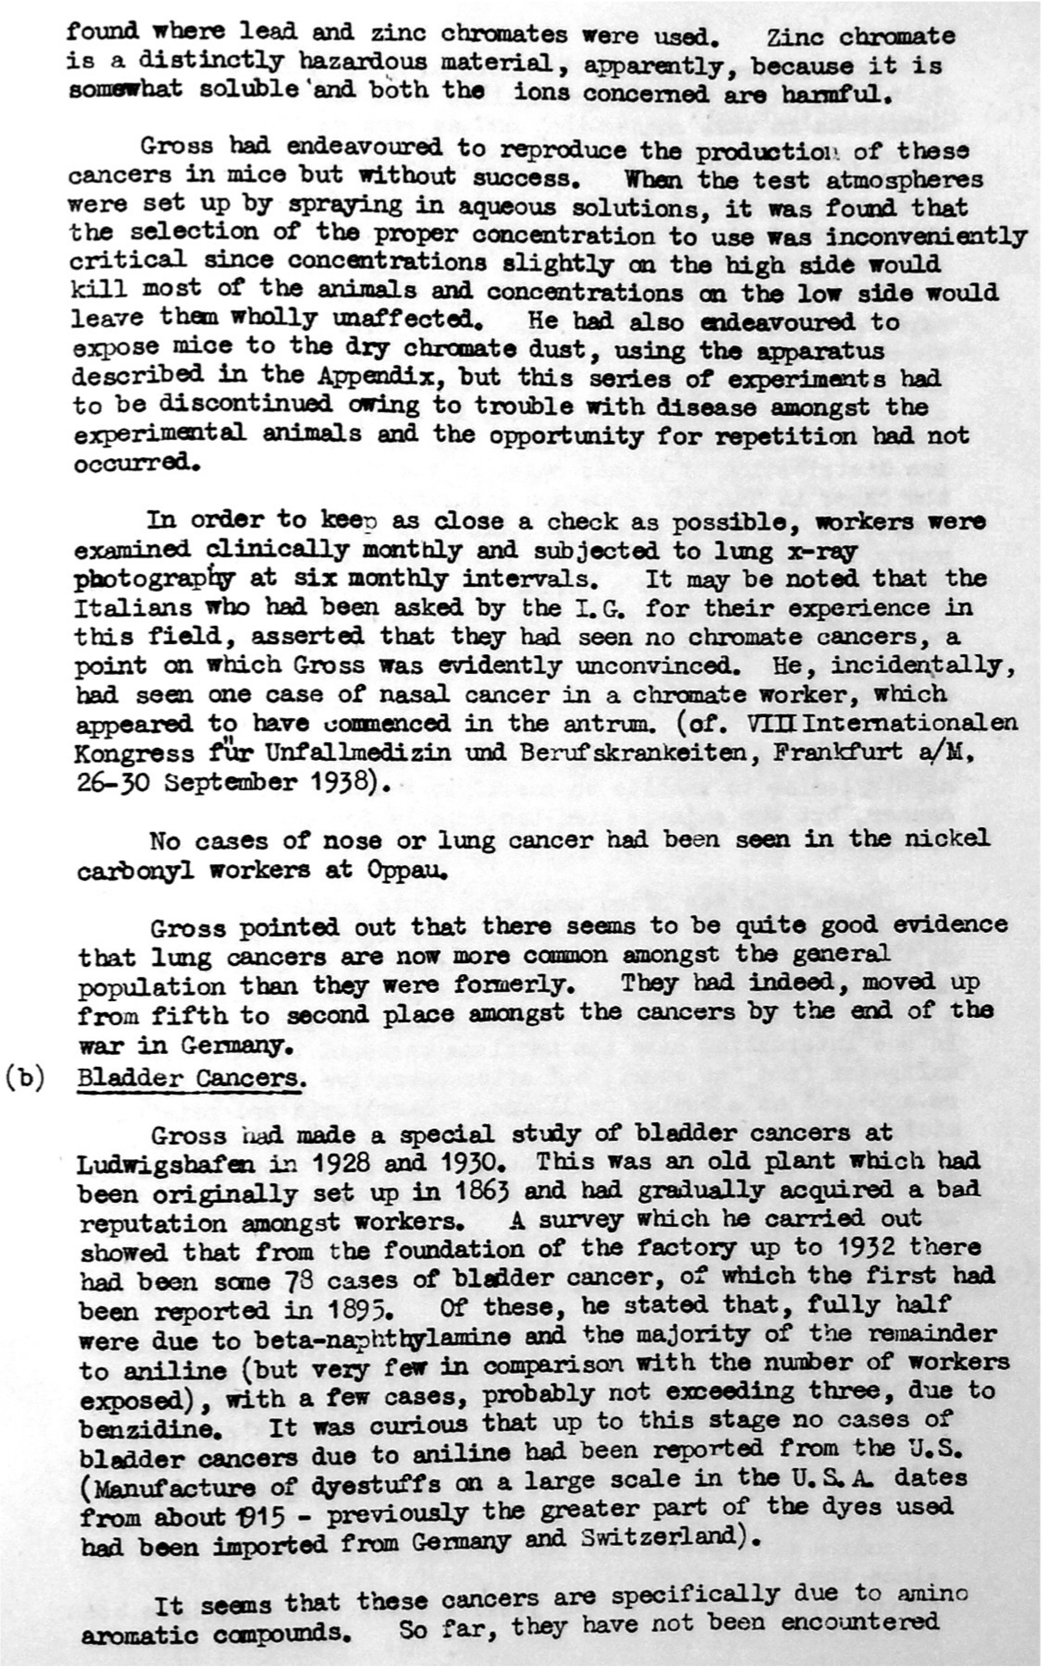
(a) Chromate Cancers

In 1910 a Dr. Pfeil at Ludwigshafen reported two cases of lung cancer amongst workers in a plant making quinone in which sodium dichromate was used as the oxidising agent. At that time there was considerable difficulty about diagnosing the complaint, and no more cases were detected for a considerable number of years. However, between 1933 and 1935 some seven or eight cases were reported from Griesheim, all of which had occurred in a plant making sodium dichromate. This was the first clue that dichromates or chromates could themselves be capable of giving rise to this disease, but the matter was complicated by the fact that the plant concerned was a somewhat old one and other hazards might have existed simultaneously. A careful survey was therefore made of all the plants in the I.G. engaged in chromate production, of which the chief were at Leverkusen, Urdingen and Bittefeld. All of these three plants were of modern construction, and this lessened the probability of other factors entering into the hazard. It was, of course, well known at the time of the construction of these plants that chromates possess an aggressive action on the nose and skin; precautions had therefore been taken. However, by means of routine lung x-ray examination, some fifty cases of lung cancer were brought to light over about ten years, involving perhaps 3 or 4% of the total number of workers at risk. All of these died within one or two years, since the disease develops extremely rapidly and in the ordinary way the chances of early recognition are slight. If, however, the disease was detected in time, arrangements were made to take the man concerned off the work and send him to a sanatorium. Secondary cancers, often in the brain and spine, were commonly seen. The most common site of the primary lesion was at the bronchial bifurcation, but occasionally they were also seen at the periphery of the lung, and on at least one of these Professor Sauerbruch carried out a spectacular operative removal, believed by Gross to have been successful.

Of those affected, about a quarter to a third had worked right up to the moment at which the illness had been detected. The duration of exposure varied greatly, from thirty down to about four years, though probably a period between ten and twenty years was most common. As with bladder cancers, to which reference is made below, the latent period may be very long - sometimes up to twenty years.

At first, the impression was gained that these lung cancers occurred only amongst workers engaged on the actual manufacture of chromates, and particularly at the stage at which the mass of sodium chromate is chipped out and dissolved in hot water, since the steam apparently carried off small particules of chromate, but in the latter years about seven cases have been

Figure A.47: Examples of studies of cancers due to workplace chemical exposure [BIOS 784].



found where lead and zinc chromates were used. Zinc chromate is a distinctly hazardous material, apparently, because it is somewhat soluble and both the ions concerned are harmful.

Gross had endeavoured to reproduce the production of these cancers in mice but without success. When the test atmospheres were set up by spraying in aqueous solutions, it was found that the selection of the proper concentration to use was inconveniently critical since concentrations slightly on the high side would kill most of the animals and concentrations on the low side would leave them wholly unaffected. He had also endeavoured to expose mice to the dry chromate dust, using the apparatus described in the Appendix, but this series of experiments had to be discontinued owing to trouble with disease amongst the experimental animals and the opportunity for repetition had not occurred.

In order to keep as close a check as possible, workers were examined clinically monthly and subjected to lung x-ray photography at six monthly intervals. It may be noted that the Italians who had been asked by the I.G. for their experience in this field, asserted that they had seen no chromate cancers, a point on which Gross was evidently unconvinced. He, incidentally, had seen one case of nasal cancer in a chromate worker, which appeared to have commenced in the antrum. (of. VIII Internationalen Kongress für Unfallmedizin und Berufskrankeiten, Frankfurt a/M, 26-30 September 1938).

No cases of nose or lung cancer had been seen in the nickel carbonyl workers at Oppau.

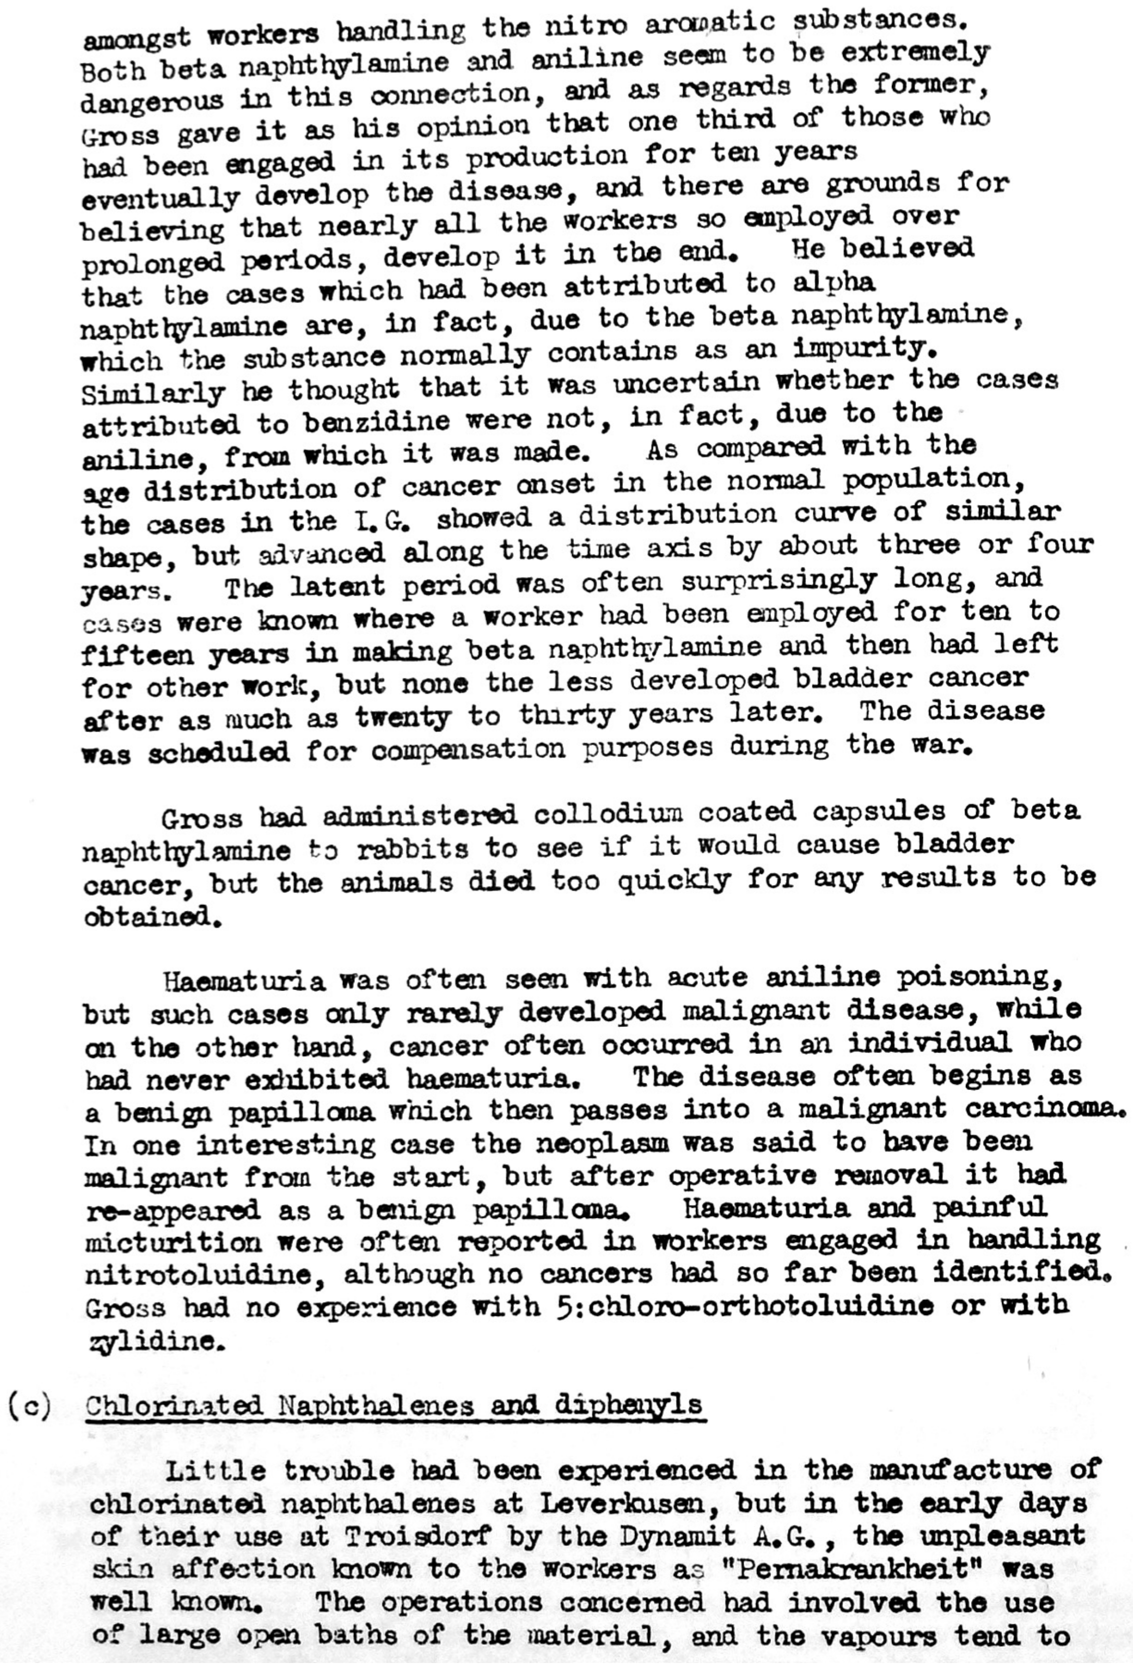
Gross pointed out that there seems to be quite good evidence that lung cancers are now more common amongst the general population than they were formerly. They had indeed, moved up from fifth to second place amongst the cancers by the end of the war in Germany.

(b) Bladder Cancers.

Gross had made a special study of bladder cancers at Ludwigshafen in 1928 and 1930. This was an old plant which had been originally set up in 1863 and had gradually acquired a bad reputation amongst workers. A survey which he carried out showed that from the foundation of the factory up to 1932 there had been some 78 cases of bladder cancer, of which the first had been reported in 1895. Of these, he stated that, fully half were due to beta-naphthylamine and the majority of the remainder to aniline (but very few in comparison with the number of workers exposed), with a few cases, probably not exceeding three, due to benzidine. It was curious that up to this stage no cases of bladder cancers due to aniline had been reported from the U.S. (Manufacture of dyestuffs on a large scale in the U.S.A. dates from about 1915 - previously the greater part of the dyes used had been imported from Germany and Switzerland).

It seems that these cancers are specifically due to amino aromatic compounds. So far, they have not been encountered

Figure A.48: Examples of studies of cancers due to workplace chemical exposure [BIOS 784].



amongst workers handling the nitro aromatic substances. Both beta naphthylamine and aniline seem to be extremely dangerous in this connection, and as regards the former, Gross gave it as his opinion that one third of those who had been engaged in its production for ten years eventually develop the disease, and there are grounds for believing that nearly all the workers so employed over prolonged periods, develop it in the end. He believed that the cases which had been attributed to alpha naphthylamine are, in fact, due to the beta naphthylamine, which the substance normally contains as an impurity. Similarly he thought that it was uncertain whether the cases attributed to benzidine were not, in fact, due to the aniline, from which it was made. As compared with the age distribution of cancer onset in the normal population, the cases in the I.G. showed a distribution curve of similar shape, but advanced along the time axis by about three or four years. The latent period was often surprisingly long, and cases were known where a worker had been employed for ten to fifteen years in making beta naphthylamine and then had left for other work, but none the less developed bladder cancer after as much as twenty to thirty years later. The disease was scheduled for compensation purposes during the war.

Gross had administered collodium coated capsules of beta naphthylamine to rabbits to see if it would cause bladder cancer, but the animals died too quickly for any results to be obtained.

Haematuria was often seen with acute aniline poisoning, but such cases only rarely developed malignant disease, while on the other hand, cancer often occurred in an individual who had never exhibited haematuria. The disease often begins as a benign papilloma which then passes into a malignant carcinoma. In one interesting case the neoplasm was said to have been malignant from the start, but after operative removal it had re-appeared as a benign papilloma. Haematuria and painful micturition were often reported in workers engaged in handling nitrotoluidine, although no cancers had so far been identified. Gross had no experience with 5:chloro-orthotoluidine or with xylidine.

(c) Chlorinated Naphthalenes and diphenyls

Little trouble had been experienced in the manufacture of chlorinated naphthalenes at Leverkusen, but in the early days of their use at Troisdorf by the Dynamit A.G., the unpleasant skin affection known to the workers as "Pernakrankheit" was well known. The operations concerned had involved the use of large open baths of the material, and the vapours tend to

BIOS 1253. ***A Photoelectric Colorimeter (Photoelectric Absorptiometer) Designed by Professor R. Havemann, Produced by W. Kauhausen in Berlin-Dahlem.***

1. GENERAL.

When visiting the Materialprüfungsanstalt, Unter den Eichen 86 Berlin-Dahlem, we found that the firm W. Kauhausen, laboratory furnishers, has an office in one of the many rooms of that building not used any more for its original purpose.

This firm is producing a photoelectric Colorimeter (photoelectric absorptiometer), designed by Professor R. Havemann, director of the Kaiser Wilhelm Institut für Elektrophysik.

The instrument was seen in the store rooms of the firm and, in operation, in the pharmacological Institute of the University Berlin, the director of which, Professor W. Heubner, has been using it on a large scale for many years and confirmed its excellent performance.

The writer things the instrument presents several interesting features worth reporting. [...]

3. PUBLICATIONS ABOUT THE INSTRUMENT.

The instrument is described in detail and illustrated in Kauhausen's catalogue. Havemann has published papers about it in Biochemische Zeitschrift, vol. 301, 1939, p. 105; vol. 306, 1940, p. 224; 310, 1942, p. 378; Angew. Chemie 54, 1941, p. 105; Zschr. f. physikal. Chemie A vol. 188, 1941, p. 182, Beiheft 48 zur Zeitschrift des Vereins deutscher Chemiker.

4. DESCRIPTION OF THE INSTRUMENT.

The instrument has the form of a horizontal cylinder mounted on short legs. As can be seen in the diagram reproduced at the end as figure 1, the light source is in the left third; it is either a 100 Watt filament lamp, or a mercury, sodium or cadmium vapour lamp (Osram Spectral Lamps). These lamps are easily interchangeable.

Monochromatic light of the following wavelengths (mu) [nanometers] becomes thus available: 326 (Cd); 365 (Hg); 435–6 (Hg); 509 (Cd); 546 (Hg); 577–9 (Hg); 589–95 (Na); 644 (Cd).

Two photocells of the barrier layer type are arranged on either side of the lamp. The left hand one—the compensating cell—is permanently fixed and has an iris diaphragm. The other one, however, on the side of the liquid under test, is mounted on a revolving spindle, the rotation of which varies the distance of the cell from the light source. This is the measuring cell. [...]

Additional equipment for fluorescence measurements can also easily be fitted.

Light-absorbing filters can be inserted on either side, producing more or less monochromatic light according to the light source chosen.

A shunt is provided for varying the sensitivity of the galvo. [...]

7. CELLS FOR THE LIQUID TO BE TESTED.

The cells taking the coloured liquid are kept in position by a spring-loaded ring, enabling a quick interchange of cells of various sizes and guaranteeing exact location of the cell position.

In addition to simple cells with depths of 5, 10, 20, 30 and 40 mm, several cells of special design are available, as shown in figures 2 to 5.

Figure 2 shows a flow through cell with very wide inflow funnel; the side tube on the right is an air outlet. The wide tubes and the absence of bends make the operations of filling and emptying rapid and simple.

Figure 3 shows a cell with a jacket in which liquid from a thermostat fitted with a pump can be circulated, so as to keep the liquid under test at a constant temperature, which is particularly useful for physico-chemical measurements.

Figure 4 shows a cell specially constructed for photometric titrations. It is fitted with a stirring device which is shewn more fully in figure 5.

The side of the cell is joined tangentially at point A and the stirrer thus acts as a centrifugal pump. The contents of the cell are mixed very rapidly and this makes the photometric titration with this apparatus much more speedy than a potentiometric or amperometric titration.

The photometric titration enables colour changes too indefinite or too delicate to be followed by simple observation to be followed with ease and great accuracy. This allows very dilute solutions to be used and the use of indicators becomes unnecessary in some cases, e.g. with iodometric and bromometric methods. [...]

9. FLUORESCENCE MEASUREMENTS.

The light from the mercury lamp first passes the filter UG2, transmitting the UV line 365 mu and some infra-red rays only. The transmitted light then passes the cell with the liquid under test and then impinges upon a filter GG8 which absorbs the UV light but transmits the infra-red and any visible fluorescent light produced in the solution. The infra-red light is then retained by a further filter BG23, so that only the light produced in consequence of fluorescent material being present impinges upon the photocell. [...]

Quartz cells are available for this type of work but it appears from the description, that glass cells can also be used, although the fluorescence of the glass interferes to some extent.

10. ACCURACY CLAIMED.

An overall accuracy of 0.2 to 0.3% is claimed. [...]

[This instrument appears to be the first true spectrophotometer, and it has all of the essential features of modern spectrophotometers. Robert Havemann (German, 1910–1982) invented spectrophotometers no later than 1936, as shown by the patents on pp. 2381–2388. This BIOS report made clear that Havemann's spectrophotometers had been extensively used in Germany for many years before Allied investigators discovered them and sent detailed documentation (and perhaps whole instruments) to the United Kingdom and United States, which presumably copied the technology. Such spectrophotometers are now used worldwide for a wide variety of biochemical and chemical measurements.]

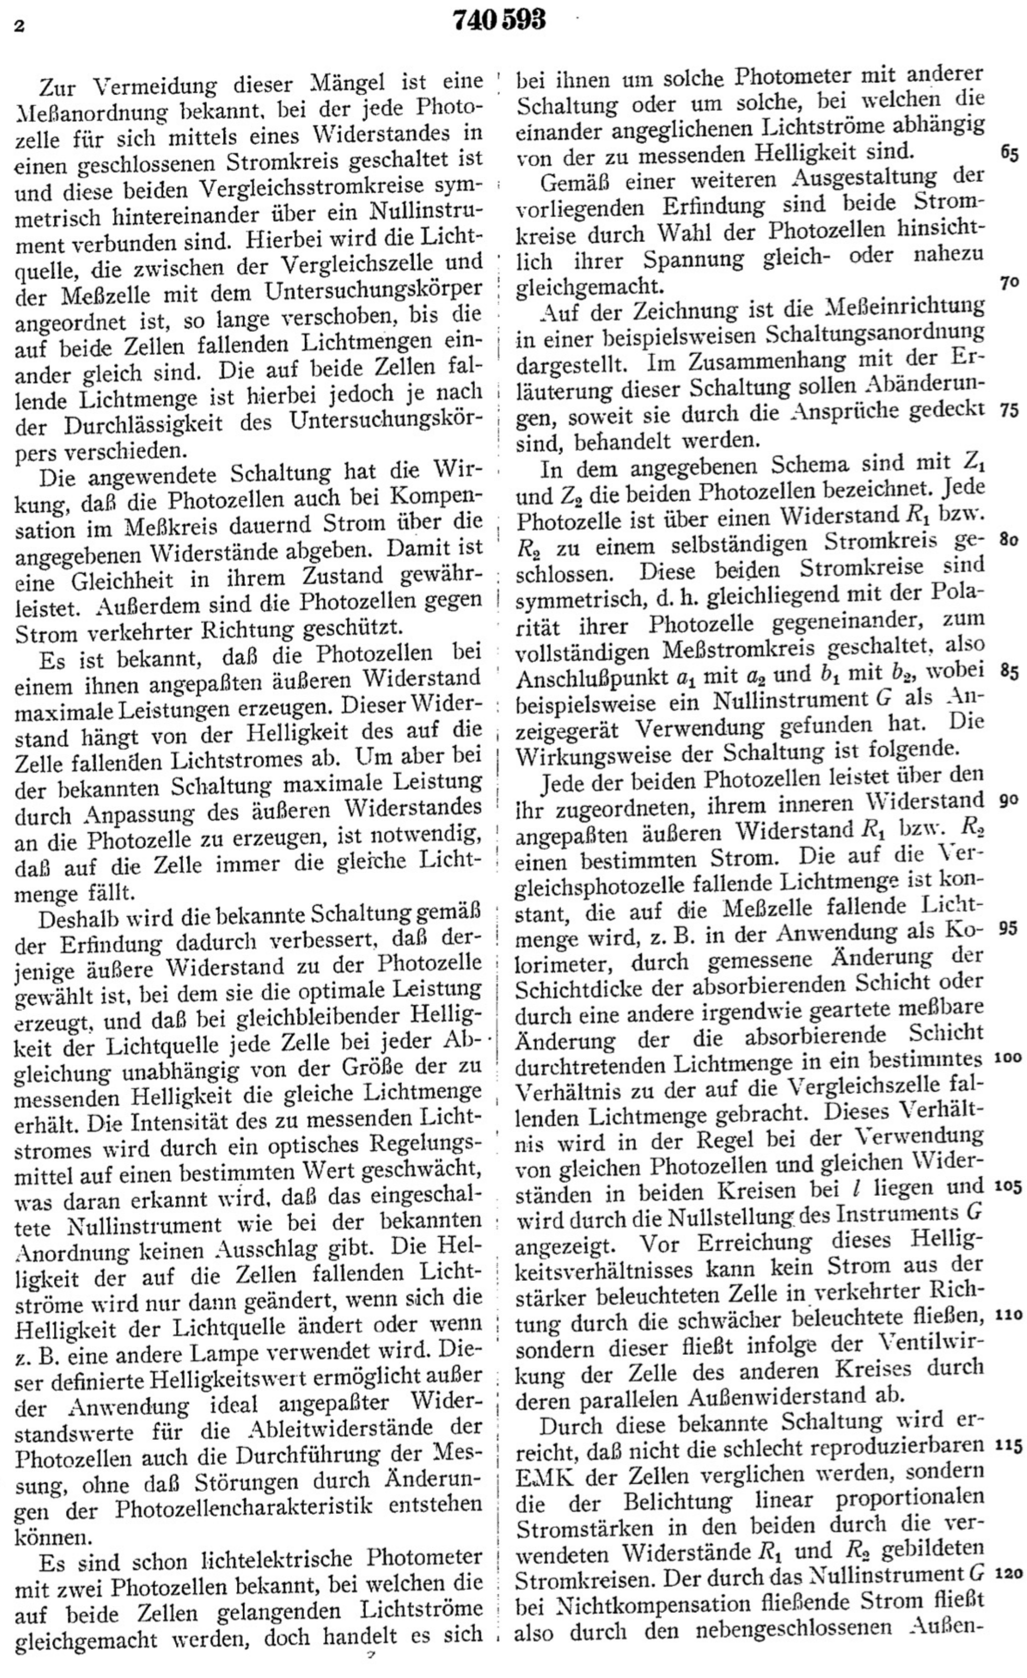
Einrichtung zum Vergleichen von Helligkeitswerten mit Hilfe von zwei Photozellen

Patentiert im Deutschen Reich vom 11. Dezember 1936 an
Patenterteilung bekanntgemacht am 2. September 1943

Die Erfindung betrifft eine Einrichtung zum Vergleichen von Helligkeitswerten, die für photometrische und kolorimetrische Messungen angewendet werden kann. Die hier in Betracht kommende Einrichtung gehört zu den bekannten Anordnungen, bei denen man zur Vermeidung verschiedener Schwierigkeiten zwei Photozellen benutzt. Die eine als Vergleichszelle bezeichnete Photozelle wird mit einer konstanten bzw. sich proportional der zu messenden Lichtintensität ändernden Lichtquelle beleuchtet. Die zweite als Meßzelle bezeichnete Photozelle wird von dem zu messenden Licht bestrahlt, wobei dessen Intensität in gemessener Weise geschwächt wird, z. B. durch eine geeichte Blende oder einen Graukeil. Bei Anwendung der normalen Kompensationsschaltung, die die Differenz der EMK der beiden Photozellen zu bestimmen gestattet, wirken sich die Helligkeitsschwankungen der Lichtquelle, die wegen der sehr steilen Helligkeitscharakteristik der modernen hochgeheizten Glühbirnen schon bei ganz geringen Schwankungen der Betriebsspannungen entstehen, nunmehr auf die Differenz der EMK der Zellen aus, aus deren Größe das Meßresultat sich unmittelbar ergibt. Abgesehen von diesem Fehler treten bei diesen Schaltungen noch die Schwierigkeiten auf, daß die elektromotorische Kraft (EMK) der Sperrschichtzellen der auffallenden Lichtmenge nicht proportional ist und die EMK bei wechselnder Belastung nicht reproduzierbar ist.

Die bisher üblichen Kompensationsschaltungen ergeben nun weitere Schwierigkeiten für die Messung. Einmal wird bei Nichtkompensierung die jeweils überkompensierte Zelle durch einen die Sperrschicht in verkehrter Richtung durchlaufenden Strom geschädigt. Sodann haben die zur Messung verwendeten Sperrschichtzellen die Eigenschaft, daß die EMK einer Zelle, die keine Arbeit über einen Widerstand leistet, nicht linear proportional der Intensität des auf sie auffallenden Lichtes ist. Die Sperrschichtzellen, die in der Technik auch als Gleichrichter Verwendung finden, haben in einer Richtung einen sehr großen, in der anderen Richtung einen kleinen Widerstand. Durchtritt eine belichtete Sperrschichtzelle ein der durch die Belichtung erzeugten EMK entgegengesetzter Strom, so tritt eine Aufhebung des die EMK erzeugenden Vorganges, eine Polarisation der Zelle ein, die bewirkt, daß nach der Polarisation die Photozelle bei der gleichen Belichtung nicht mehr dieselbe EMK erzeugt wie vorher.

Figure A.51: Robert Havemann invented the spectrophotometer in 1936.



Zur Vermeidung dieser Mängel ist eine Meßanordnung bekannt, bei der jede Photozelle für sich mittels eines Widerstandes in einen geschlossenen Stromkreis geschaltet ist und diese beiden Vergleichsstromkreise symmetrisch hintereinander über ein Nullinstrument verbunden sind. Hierbei wird die Lichtquelle, die zwischen der Vergleichszelle und der Meßzelle mit dem Untersuchungskörper angeordnet ist, so lange verschoben, bis die auf beide Zellen fallenden Lichtmengen einander gleich sind. Die auf beide Zellen fallende Lichtmenge ist hierbei jedoch je nach der Durchlässigkeit des Untersuchungskörpers verschieden.

Die angewendete Schaltung hat die Wirkung, daß die Photozellen auch bei Kompensation im Meßkreis dauernd Strom über die angegebenen Widerstände abgeben. Damit ist eine Gleichheit in ihrem Zustand gewährleistet. Außerdem sind die Photozellen gegen Strom verkehrter Richtung geschützt.

Es ist bekannt, daß die Photozellen bei einem ihnen angepaßten äußeren Widerstand maximale Leistungen erzeugen. Dieser Widerstand hängt von der Helligkeit des auf die Zelle fallenden Lichtstromes ab. Um aber bei der bekannten Schaltung maximale Leistung durch Anpassung des äußeren Widerstandes an die Photozelle zu erzeugen, ist notwendig, daß auf die Zelle immer die gleiche Lichtmenge fällt.

Deshalb wird die bekannte Schaltung gemäß der Erfindung dadurch verbessert, daß derjenige äußere Widerstand zu der Photozelle gewählt ist, bei dem sie die optimale Leistung erzeugt, und daß bei gleichbleibender Helligkeit der Lichtquelle jede Zelle bei jeder Abgleichung unabhängig von der Größe der zu messenden Helligkeit die gleiche Lichtmenge erhält. Die Intensität des zu messenden Lichtstromes wird durch ein optisches Regelungsmittel auf einen bestimmten Wert geschwächt, was daran erkannt wird, daß das eingeschaltete Nullinstrument wie bei der bekannten Anordnung keinen Ausschlag gibt. Die Helligkeit der auf die Zellen fallenden Lichtströme wird nur dann geändert, wenn sich die Helligkeit der Lichtquelle ändert oder wenn z. B. eine andere Lampe verwendet wird. Dieser definierte Helligkeitswert ermöglicht außer der Anwendung ideal angepaßter Widerstandswerte für die Ableitwiderstände der Photozellen auch die Durchführung der Messung, ohne daß Störungen durch Änderungen der Photozellencharakteristik entstehen können.

Es sind schon lichtelektrische Photometer mit zwei Photozellen bekannt, bei welchen die auf beide Zellen gelangenden Lichtströme gleichgemacht werden, doch handelt es sich bei ihnen um solche Photometer mit anderer Schaltung oder um solche, bei welchen die einander angeglichenen Lichtströme abhängig von der zu messenden Helligkeit sind.

Gemäß einer weiteren Ausgestaltung der vorliegenden Erfindung sind beide Stromkreise durch Wahl der Photozellen hinsichtlich ihrer Spannung gleich- oder nahezu gleichgemacht.

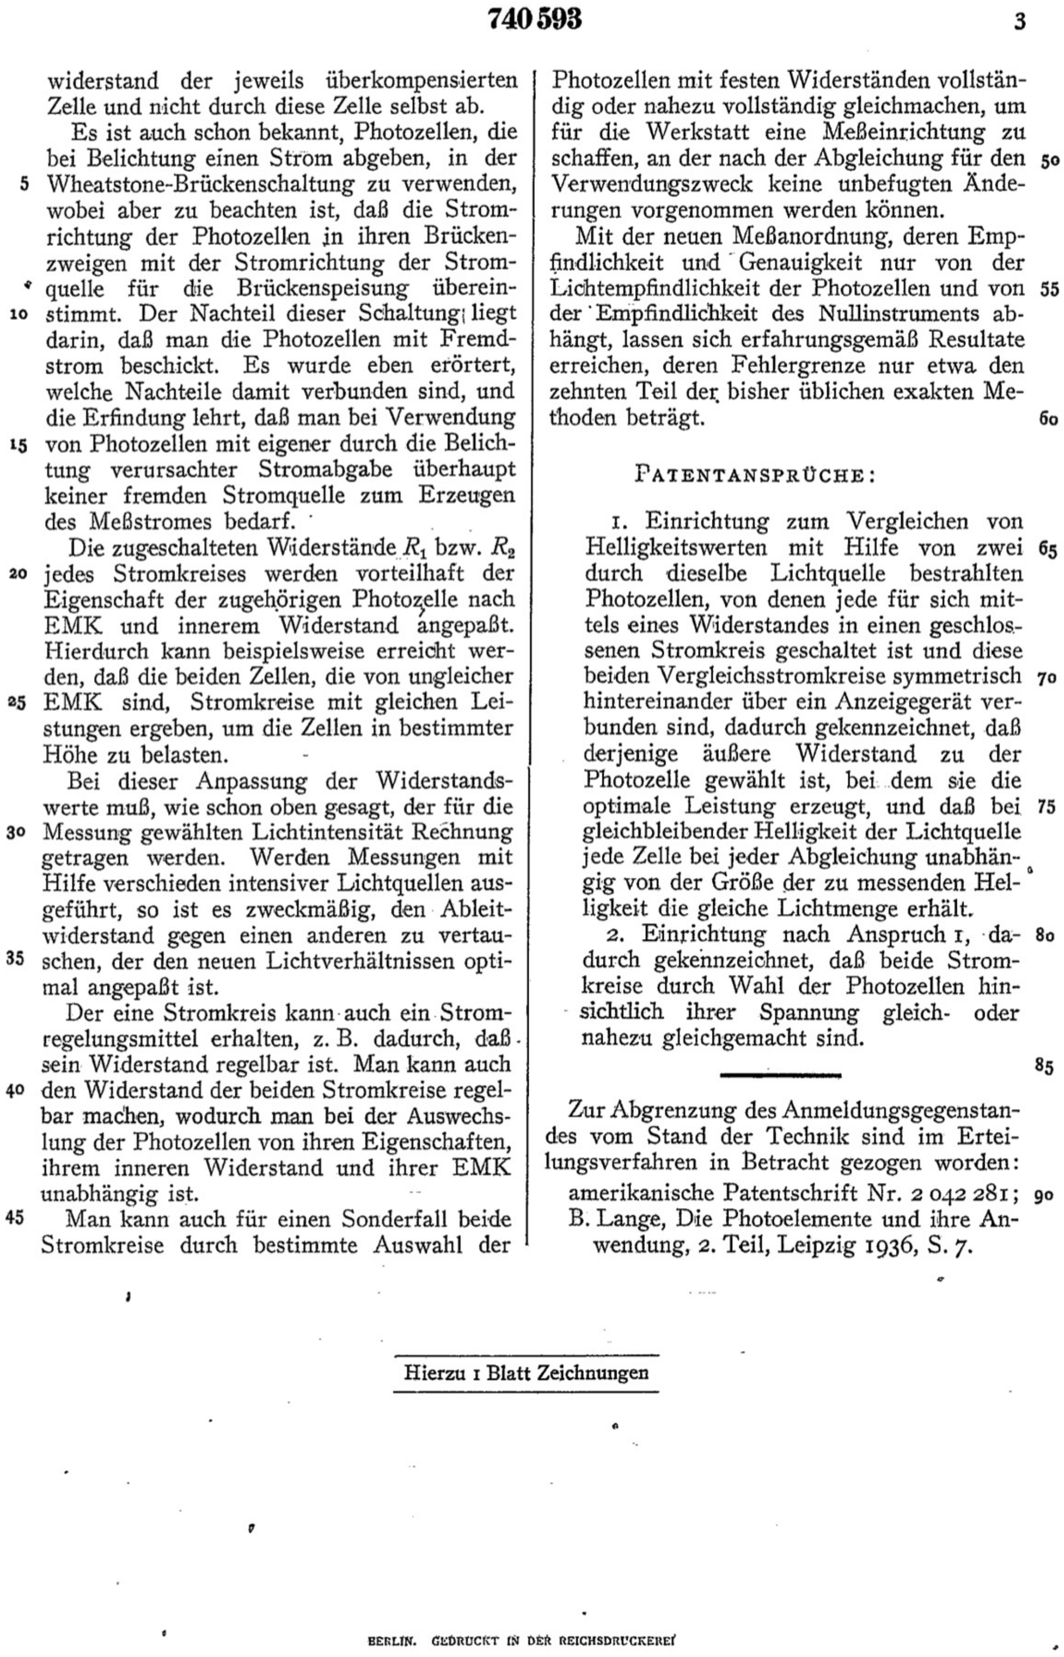
Auf der Zeichnung ist die Meßeinrichtung in einer beispielsweisen Schaltungsanordnung dargestellt. Im Zusammenhang mit der Erläuterung dieser Schaltung sollen Abänderungen, soweit sie durch die Ansprüche gedeckt sind, behandelt werden.

In dem angegebenen Schema sind mit Z_1 und Z_2 die beiden Photozellen bezeichnet. Jede Photozelle ist über einen Widerstand R_1 bzw. R_2 zu einem selbständigen Stromkreis geschlossen. Diese beiden Stromkreise sind symmetrisch, d. h. gleichliegend mit der Polarität ihrer Photozelle gegeneinander, zum vollständigen Meßstromkreis geschaltet, also Anschlußpunkt a_1 mit a_2 und b_1 mit b_2, wobei beispielsweise ein Nullinstrument G als Anzeigegerät Verwendung gefunden hat. Die Wirkungsweise der Schaltung ist folgende.

Jede der beiden Photozellen leistet über den ihr zugeordneten, ihrem inneren Widerstand angepaßten äußeren Widerstand R_1 bzw. R_2 einen bestimmten Strom. Die auf die Vergleichsphotozelle fallende Lichtmenge ist konstant, die auf die Meßzelle fallende Lichtmenge wird, z. B. in der Anwendung als Kolorimeter, durch gemessene Änderung der Schichtdicke der absorbierenden Schicht oder durch eine andere irgendwie geartete meßbare Änderung der die absorbierende Schicht durchtretenden Lichtmenge in ein bestimmtes Verhältnis zu der auf die Vergleichszelle fallenden Lichtmenge gebracht. Dieses Verhältnis wird in der Regel bei der Verwendung von gleichen Photozellen und gleichen Widerständen in beiden Kreisen bei l liegen und wird durch die Nullstellung des Instruments G angezeigt. Vor Erreichung dieses Helligkeitsverhältnisses kann kein Strom aus der stärker beleuchteten Zelle in verkehrter Richtung durch die schwächer beleuchtete fließen, sondern dieser fließt infolge der Ventilwirkung der Zelle des anderen Kreises durch deren parallelen Außenwiderstand ab.

Durch diese bekannte Schaltung wird erreicht, daß nicht die schlecht reproduzierbaren EMK der Zellen verglichen werden, sondern die der Belichtung linear proportionalen Stromstärken in den beiden durch die verwendeten Widerstände R_1 und R_2 gebildeten Stromkreisen. Der durch das Nullinstrument G bei Nichtkompensation fließende Strom fließt also durch den nebengeschlossenen Außen-

Figure A.52: Robert Havemann invented the spectrophotometer in 1936.



widerstand der jeweils überkompensierten Zelle und nicht durch diese Zelle selbst ab.

Es ist auch schon bekannt, Photozellen, die bei Belichtung einen Strom abgeben, in der Wheatstone-Brückenschaltung zu verwenden, wobei aber zu beachten ist, daß die Stromrichtung der Photozellen in ihren Brückenzweigen mit der Stromrichtung der Stromquelle für die Brückenspeisung übereinstimmt. Der Nachteil dieser Schaltung liegt darin, daß man die Photozellen mit Fremdstrom beschickt. Es wurde eben erörtert, welche Nachteile damit verbunden sind, und die Erfindung lehrt, daß man bei Verwendung von Photozellen mit eigener durch die Belichtung verursachter Stromabgabe überhaupt keiner fremden Stromquelle zum Erzeugen des Meßstromes bedarf.

Die zugeschalteten Widerstände R_1 bzw. R_2 jedes Stromkreises werden vorteilhaft der Eigenschaft der zugehörigen Photozelle nach EMK und innerem Widerstand angepaßt. Hierdurch kann beispielsweise erreicht werden, daß die beiden Zellen, die von ungleicher EMK sind, Stromkreise mit gleichen Leistungen ergeben, um die Zellen in bestimmter Höhe zu belasten.

Bei dieser Anpassung der Widerstandswerte muß, wie schon oben gesagt, der für die Messung gewählten Lichtintensität Rechnung getragen werden. Werden Messungen mit Hilfe verschieden intensiver Lichtquellen ausgeführt, so ist es zweckmäßig, den Ableitwiderstand gegen einen anderen zu vertauschen, der den neuen Lichtverhältnissen optimal angepaßt ist.

Der eine Stromkreis kann auch ein Stromregelungsmittel erhalten, z. B. dadurch, daß sein Widerstand regelbar ist. Man kann auch den Widerstand der beiden Stromkreise regelbar machen, wodurch man bei der Auswechslung der Photozellen von ihren Eigenschaften, ihrem inneren Widerstand und ihrer EMK unabhängig ist.

Man kann auch für einen Sonderfall beide Stromkreise durch bestimmte Auswahl der Photozellen mit festen Widerständen vollständig oder nahezu vollständig gleichmachen, um für die Werkstatt eine Meßeinrichtung zu schaffen, an der nach der Abgleichung für den Verwendungszweck keine unbefugten Änderungen vorgenommen werden können.

Mit der neuen Meßanordnung, deren Empfindlichkeit und Genauigkeit nur von der Lichtempfindlichkeit der Photozellen und von der Empfindlichkeit des Nullinstruments abhängt, lassen sich erfahrungsgemäß Resultate erreichen, deren Fehlergrenze nur etwa den zehnten Teil der bisher üblichen exakten Methoden beträgt.

PATENTANSPRÜCHE:

1. Einrichtung zum Vergleichen von Helligkeitswerten mit Hilfe von zwei durch dieselbe Lichtquelle bestrahlten Photozellen, von denen jede für sich mittels eines Widerstandes in einen geschlossenen Stromkreis geschaltet ist und diese beiden Vergleichsstromkreise symmetrisch hintereinander über ein Anzeigegerät verbunden sind, dadurch gekennzeichnet, daß derjenige äußere Widerstand zu der Photozelle gewählt ist, bei dem sie die optimale Leistung erzeugt, und daß bei gleichbleibender Helligkeit der Lichtquelle jede Zelle bei jeder Abgleichung unabhängig von der Größe der zu messenden Helligkeit die gleiche Lichtmenge erhält.

2. Einrichtung nach Anspruch 1, dadurch gekennzeichnet, daß beide Stromkreise durch Wahl der Photozellen hinsichtlich ihrer Spannung gleich- oder nahezu gleichgemacht sind.

Zur Abgrenzung des Anmeldungsgegenstandes vom Stand der Technik sind im Erteilungsverfahren in Betracht gezogen worden:

Dr. Robert Havemann in Berlin-Charlottenburg

Einrichtung zum Messen von Helligkeitswerten mit Hilfe von zwei lichtelektrischen Zellen

Patentiert im Deutschen Reich vom 11. Januar 1939 an

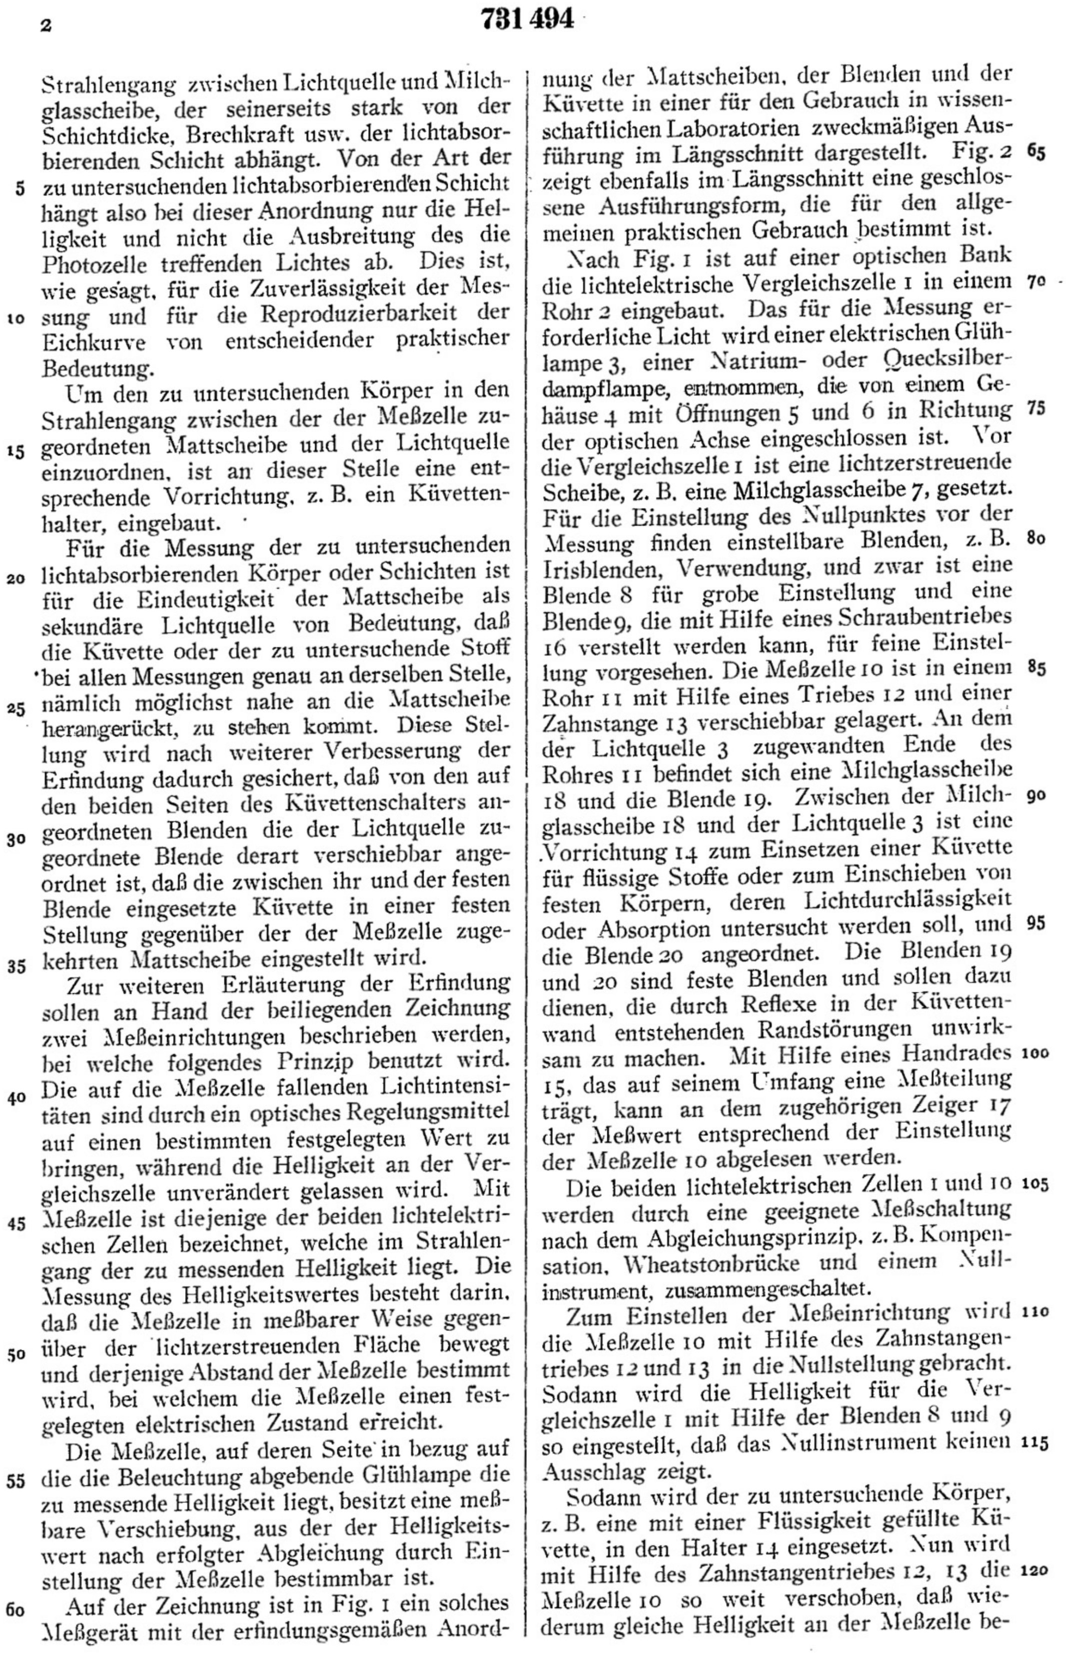
Patenterteilung bekanntgemacht am 7. Januar 1943

Es sind Einrichtungen zum Messen von Helligkeitswerten mit Hilfe von zwei lichtelektrischen Zellen und einer optischen Abgleichung der Lichtwege bekannt. Hierbei werden als zu vergleichende Helligkeiten beleuchtete, lichtzerstreuende Flächen, z. B. Matt- oder Milchglasscheiben, verwendet, die durch eine gemeinsame Glühlampe beleuchtet werden, um den Einfluß von Helligkeitsschwankungen der Lichtquelle auszuschalten. Zwar sind beleuchtete Mattscheiben als sekundäre Lichtquelle bei lichtelektrischen Messungen bekannt, jedoch dient diese Verwendung nur dem Zweck, die störenden Wirkungen der ungleichmäßigen Lichtempfindlichkeit der Zellen in den verschiedenen Punkten ihrer Oberfläche auszugleichen.

Bei dem Gegenstand der vorliegenden Erfindung dagegen ist als eigentliches Ziel gesetzt, eine für die Meßzellen maßgebliche Lichtquelle zu schaffen, die in der Art ihrer Lichtausstrahlung unabhängig ist von der Schichtdicke und der Art der zu untersuchenden lichtabsorbierenden Substanzen.

Bei Einrichtungen zum Messen von Helligkeitswerten mit Hilfe von zwei lichtelektrischen Zellen für photometrische oder kolorimetrische Messungen wurde bekannt, daß die Stellung der Mattscheibe für die Zuverlässigkeit der Messung von wesentlicher Bedeutung ist. Auf Grund dieser Erkenntnis wird gemäß der Erfindung bei einer Einrichtung zum Messen von Helligkeitswerten mit Hilfe von zwei lichtelektrischen Zellen und einer optischen Abgleichung der Lichtwege, bei welcher die zu vergleichenden Helligkeiten durch Beleuchtung von lichtzerstreuenden Mattscheiben erzeugt werden, die Milchglas- oder Mattscheibe feststehend zwischen der verschiebbaren Meßzelle und dem zu untersuchenden Medium angeordnet. Bei der Messung wird demnach die Milchglasscheibe von dem Licht beleuchtet, das, von der Lichtquelle kommend, die zu untersuchenden lichtabsorbierenden Schichten durchdrungen hat. Infolge der lichtzerstreuenden Eigenschaften der Milchglasscheibe ist der Strahlengang zwischen ihr und der Photozelle unabhängig vom

Figure A.55: Robert Havemann invented the spectrophotometer in 1936.



2

731 494

Strahlengang zwischen Lichtquelle und Milchglasscheibe, der seinerseits stark von der Schichtdicke, Brechkraft usw. der lichtabsorbierenden Schicht abhängt. Von der Art der zu untersuchenden lichtabsorbierenden Schicht hängt also bei dieser Anordnung nur die Helligkeit und nicht die Ausbreitung des die Photozelle treffenden Lichtes ab. Dies ist, wie gesagt, für die Zuverlässigkeit der Messung und für die Reproduzierbarkeit der Eichkurve von entscheidender praktischer Bedeutung.

Um den zu untersuchenden Körper in den Strahlengang zwischen der der Meßzelle zugeordneten Mattscheibe und der Lichtquelle einzuordnen, ist an dieser Stelle eine entsprechende Vorrichtung, z. B. ein Küvettenhalter, eingebaut.

Für die Messung der zu untersuchenden lichtabsorbierenden Körper oder Schichten ist für die Eindeutigkeit der Mattscheibe als sekundäre Lichtquelle von Bedeutung, daß die Küvette oder der zu untersuchende Stoff bei allen Messungen genau an derselben Stelle, nämlich möglichst nahe an die Mattscheibe herangerückt, zu stehen kommt. Diese Stellung wird nach weiterer Verbesserung der Erfindung dadurch gesichert, daß von den auf den beiden Seiten des Küvettenschalters angeordneten Blenden die der Lichtquelle zugeordnete Blende derart verschiebbar angeordnet ist, daß die zwischen ihr und der festen Blende eingesetzte Küvette in einer festen Stellung gegenüber der der Meßzelle zugekehrten Mattscheibe eingestellt wird.

Zur weiteren Erläuterung der Erfindung sollen an Hand der beiliegenden Zeichnung zwei Meßeinrichtungen beschrieben werden, bei welche folgendes Prinzip benutzt wird. Die auf die Meßzelle fallenden Lichtintensitäten sind durch ein optisches Regelungsmittel auf einen bestimmten festgelegten Wert zu bringen, während die Helligkeit an der Vergleichszelle unverändert gelassen wird. Mit Meßzelle ist diejenige der beiden lichtelektrischen Zellen bezeichnet, welche im Strahlengang der zu messenden Helligkeit liegt. Die Messung des Helligkeitswertes besteht darin, daß die Meßzelle in meßbarer Weise gegenüber der lichtzerstreuenden Fläche bewegt und derjenige Abstand der Meßzelle bestimmt wird, bei welchem die Meßzelle einen festgelegten elektrischen Zustand erreicht.

Die Meßzelle, auf deren Seite in bezug auf die die Beleuchtung abgebende Glühlampe die zu messende Helligkeit liegt, besitzt eine meßbare Verschiebung, aus der der Helligkeitswert nach erfolgter Abgleichung durch Einstellung der Meßzelle bestimmbar ist.

Auf der Zeichnung ist in Fig. 1 ein solches Meßgerät mit der erfindungsgemäßen Anordnung der Mattscheiben, der Blenden und der Küvette in einer für den Gebrauch in wissenschaftlichen Laboratorien zweckmäßigen Ausführung im Längsschnitt dargestellt. Fig. 2 zeigt ebenfalls im Längsschnitt eine geschlossene Ausführungsform, die für den allgemeinen praktischen Gebrauch bestimmt ist.

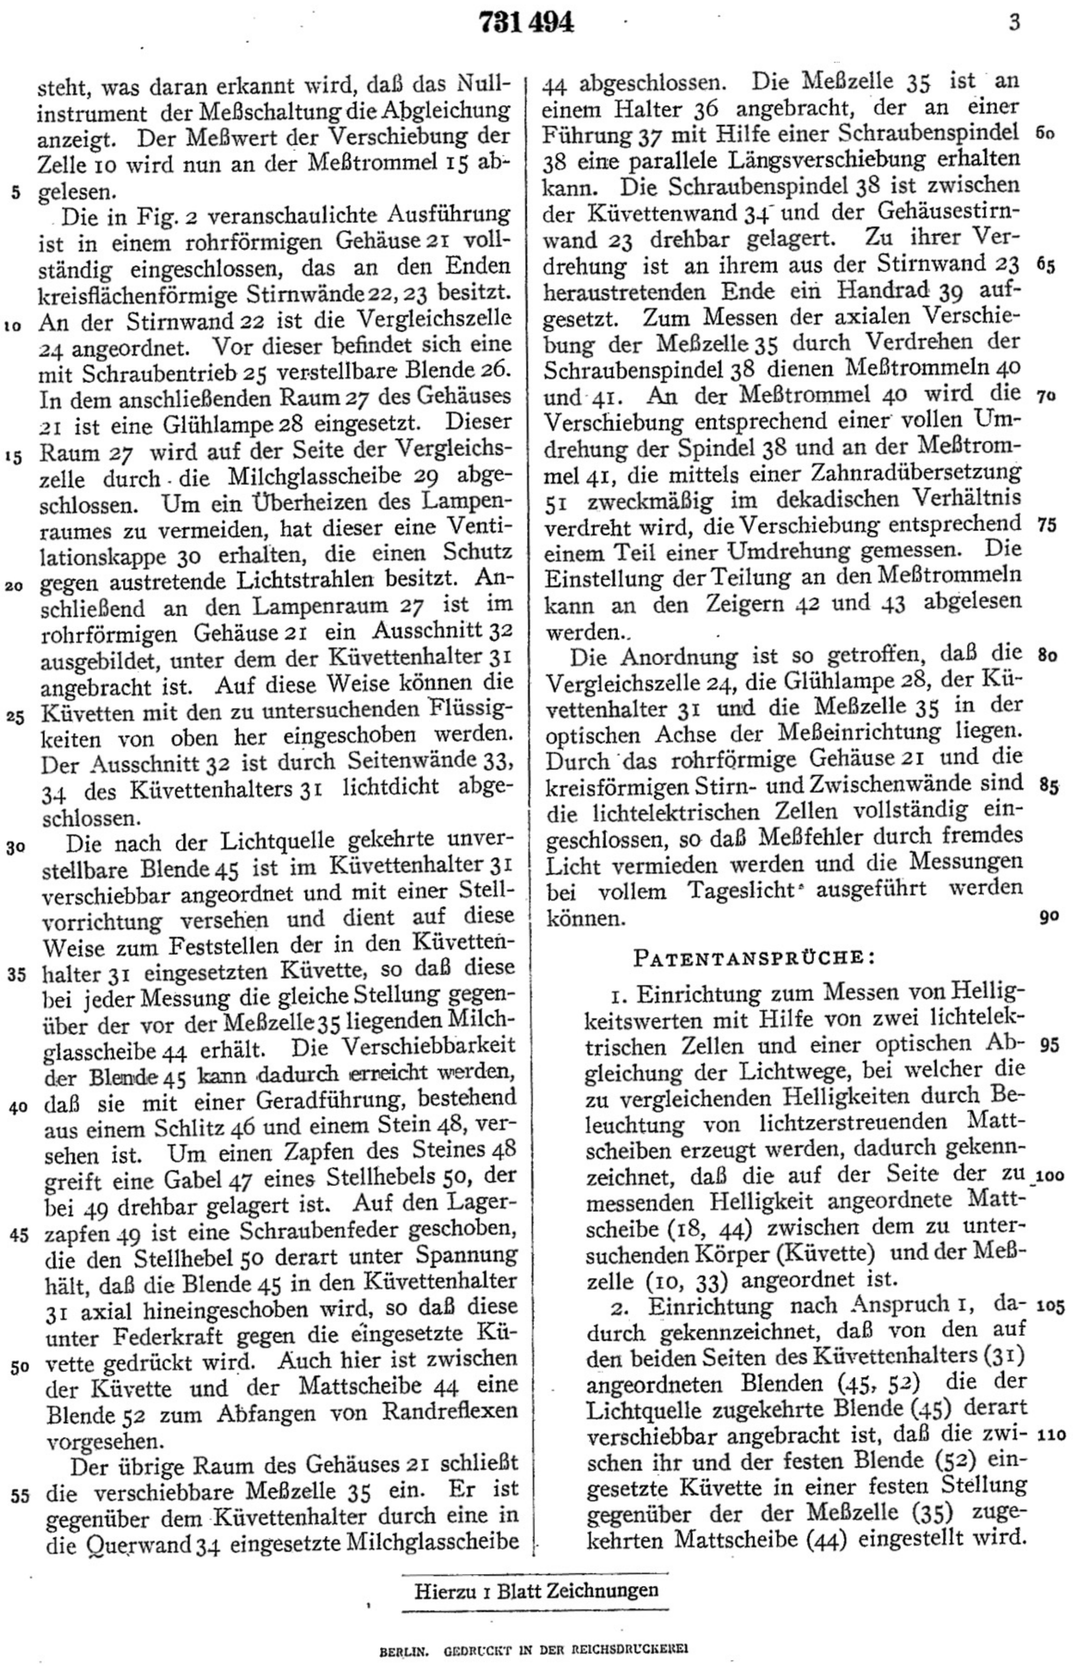
Nach Fig. 1 ist auf einer optischen Bank die lichtelektrische Vergleichszelle 1 in einem Rohr 2 eingebaut. Das für die Messung erforderliche Licht wird einer elektrischen Glühlampe 3, einer Natrium- oder Quecksilberdampflampe, entnommen, die von einem Gehäuse 4 mit Öffnungen 5 und 6 in Richtung der optischen Achse eingeschlossen ist. Vor die Vergleichszelle 1 ist eine lichtzerstreuende Scheibe, z. B. eine Milchglasscheibe 7, gesetzt. Für die Einstellung des Nullpunktes vor der Messung finden einstellbare Blenden, z. B. Irisblenden, Verwendung, und zwar ist eine Blende 8 für grobe Einstellung und eine Blende 9, die mit Hilfe eines Schraubentriebes 16 verstellt werden kann, für feine Einstellung vorgesehen. Die Meßzelle 10 ist in einem Rohr 11 mit Hilfe eines Triebes 12 und einer Zahnstange 13 verschiebbar gelagert. An dem der Lichtquelle 3 zugewandten Ende des Rohres 11 befindet sich eine Milchglasscheibe 18 und die Blende 19. Zwischen der Milchglasscheibe 18 und der Lichtquelle 3 ist eine Vorrichtung 14 zum Einsetzen einer Küvette für flüssige Stoffe oder zum Einschieben von festen Körpern, deren Lichtdurchlässigkeit oder Absorption untersucht werden soll, und die Blende 20 angeordnet. Die Blenden 19 und 20 sind feste Blenden und sollen dazu dienen, die durch Reflexe in der Küvettenwand entstehenden Randstörungen unwirksam zu machen. Mit Hilfe eines Handrades 15, das auf seinem Umfang eine Meßteilung trägt, kann an dem zugehörigen Zeiger 17 der Meßwert entsprechend der Einstellung der Meßzelle 10 abgelesen werden.

Die beiden lichtelektrischen Zellen 1 und 10 werden durch eine geeignete Meßschaltung nach dem Abgleichungsprinzip, z. B. Kompensation, Wheatstonbrücke und einem Nullinstrument, zusammengeschaltet.

Zum Einstellen der Meßeinrichtung wird die Meßzelle 10 mit Hilfe des Zahnstangentriebes 12 und 13 in die Nullstellung gebracht. Sodann wird die Helligkeit für die Vergleichszelle 1 mit Hilfe der Blenden 8 und 9 so eingestellt, daß das Nullinstrument keinen Ausschlag zeigt.

Sodann wird der zu untersuchende Körper, z. B. eine mit einer Flüssigkeit gefüllte Küvette, in den Halter 14 eingesetzt. Nun wird mit Hilfe des Zahnstangentriebes 12, 13 die Meßzelle 10 so weit verschoben, daß wiederum gleiche Helligkeit an der Meßzelle be-

Figure A.56: Robert Havemann invented the spectrophotometer in 1936.



731 494 3

steht, was daran erkannt wird, daß das Nullinstrument der Meßschaltung die Abgleichung anzeigt. Der Meßwert der Verschiebung der Zelle 10 wird nun an der Meßtrommel 15 abgelesen.

Die in Fig. 2 veranschaulichte Ausführung ist in einem rohrförmigen Gehäuse 21 vollständig eingeschlossen, das an den Enden kreisflächenförmige Stirnwände 22, 23 besitzt. An der Stirnwand 22 ist die Vergleichszelle 24 angeordnet. Vor dieser befindet sich eine mit Schraubentrieb 25 verstellbare Blende 26. In dem anschließenden Raum 27 des Gehäuses 21 ist eine Glühlampe 28 eingesetzt. Dieser Raum 27 wird auf der Seite der Vergleichszelle durch die Milchglasscheibe 29 abgeschlossen. Um ein Überheizen des Lampenraumes zu vermeiden, hat dieser eine Ventilationskappe 30 erhalten, die einen Schutz gegen austretende Lichtstrahlen besitzt. Anschließend an den Lampenraum 27 ist im rohrförmigen Gehäuse 21 ein Ausschnitt 32 ausgebildet, unter dem der Küvettenhalter 31 angebracht ist. Auf diese Weise können die Küvetten mit den zu untersuchenden Flüssigkeiten von oben her eingeschoben werden. Der Ausschnitt 32 ist durch Seitenwände 33, 34 des Küvettenhalters 31 lichtdicht abgeschlossen.

Die nach der Lichtquelle gekehrte unverstellbare Blende 45 ist im Küvettenhalter 31 verschiebbar angeordnet und mit einer Stellvorrichtung versehen und dient auf diese Weise zum Feststellen der in den Küvettenhalter 31 eingesetzten Küvette, so daß diese bei jeder Messung die gleiche Stellung gegenüber der vor der Meßzelle 35 liegenden Milchglasscheibe 44 erhält. Die Verschiebbarkeit der Blende 45 kann dadurch erreicht werden, daß sie mit einer Geradführung, bestehend aus einem Schlitz 46 und einem Stein 48, versehen ist. Um einen Zapfen des Steines 48 greift eine Gabel 47 eines Stellhebels 50, der bei 49 drehbar gelagert ist. Auf den Lagerzapfen 49 ist eine Schraubenfeder geschoben, die den Stellhebel 50 derart unter Spannung hält, daß die Blende 45 in den Küvettenhalter 31 axial hineingeschoben wird, so daß diese unter Federkraft gegen die eingesetzte Küvette gedrückt wird. Auch hier ist zwischen der Küvette und der Mattscheibe 44 eine Blende 52 zum Abfangen von Randreflexen vorgesehen.

Der übrige Raum des Gehäuses 21 schließt die verschiebbare Meßzelle 35 ein. Er ist gegenüber dem Küvettenhalter durch eine in die Querwand 34 eingesetzte Milchglasscheibe 44 abgeschlossen. Die Meßzelle 35 ist an einem Halter 36 angebracht, der an einer Führung 37 mit Hilfe einer Schraubenspindel 38 eine parallele Längsverschiebung erhalten kann. Die Schraubenspindel 38 ist zwischen der Küvettenwand 34 und der Gehäusestirnwand 23 drehbar gelagert. Zu ihrer Verdrehung ist an ihrem aus der Stirnwand 23 heraustretenden Ende ein Handrad 39 aufgesetzt. Zum Messen der axialen Verschiebung der Meßzelle 35 durch Verdrehen der Schraubenspindel 38 dienen Meßtrommeln 40 und 41. An der Meßtrommel 40 wird die Verschiebung entsprechend einer vollen Umdrehung der Spindel 38 und an der Meßtrommel 41, die mittels einer Zahnradübersetzung 51 zweckmäßig im dekadischen Verhältnis verdreht wird, die Verschiebung entsprechend einem Teil einer Umdrehung gemessen. Die Einstellung der Teilung an den Meßtrommeln kann an den Zeigern 42 und 43 abgelesen werden.

Die Anordnung ist so getroffen, daß die Vergleichszelle 24, die Glühlampe 28, der Küvettenhalter 31 und die Meßzelle 35 in der optischen Achse der Meßeinrichtung liegen. Durch das rohrförmige Gehäuse 21 und die kreisförmigen Stirn- und Zwischenwände sind die lichtelektrischen Zellen vollständig eingeschlossen, so daß Meßfehler durch fremdes Licht vermieden werden und die Messungen bei vollem Tageslicht ausgeführt werden können.

PATENTANSPRÜCHE:

1. Einrichtung zum Messen von Helligkeitswerten mit Hilfe von zwei lichtelektrischen Zellen und einer optischen Abgleichung der Lichtwege, bei welcher die zu vergleichenden Helligkeiten durch Beleuchtung von lichtzerstreuenden Mattscheiben erzeugt werden, dadurch gekennzeichnet, daß die auf der Seite der zu messenden Helligkeit angeordnete Mattscheibe (18, 44) zwischen dem zu untersuchenden Körper (Küvette) und der Meßzelle (10, 33) angeordnet ist.

2. Einrichtung nach Anspruch 1, dadurch gekennzeichnet, daß von den auf den beiden Seiten des Küvettenhalters (31) angeordneten Blenden (45, 52) die der Lichtquelle zugekehrte Blende (45) derart verschiebbar angebracht ist, daß die zwischen ihr und der festen Blende (52) eingesetzte Küvette in einer festen Stellung gegenüber der der Meßzelle (35) zugekehrten Mattscheibe (44) eingestellt wird.

BIOS 1320. ***Preparation of Biological Products at Selected Targets in Germany.*** [Lots of vaccines, hormones extracted from organs, serums, etc.]

[pp. 81–82:]

Professor Kuhn was interviewed at FIAT Main-Hoechst[...]

3065 (i) Kuhn maintained that he at no stage proposed the oral administration of this drug. The substance is inactivated by protein (e.g. broth) with which it combines, and must be tested in a synthetic medium. It has been used effectively in local applications particularly in combination with sulpha drugs (for burns) as it is not inactivated by p-amino benzoic acid. Recent clinical reports are very favourable and Kuhn promised to have a summary of these prepared.

(ii) For intestinal infections experimental work and clinical trials have been carried out with the colourless diacetyl derivative of di-bromsalicil. This substance has a very low toxicity so that large doses can be given. It is however, very rapidly hydrolysed in the gut and thus a high local concentration of the hydrolysed drug can be achieved in amount above that rendered inactive by protein combination. A clinical trial on children with intestinal infections is being carried out under the supervision of Fr. Dr. Knöwenagel. Both drugs are, according to Kuhn, more expensive to produce than the usual sulpha drugs.

Other Investigations:

(i) The alkaloid claimed by Kuhn and co-workers to be present in Colorado beetle resistant strains of the potato plant and to be responsible for the protection of the plant has been isolated in a crystalline condition. It appears to be of the solanine type. The pure alkaloid has been shown to be markedly toxic to larvae of the Colorado beetle.

(ii) Work is being continued on the biochemistry of differential growth control but this was not discussed in detail. [...]

[pp. 85–86:]

Experimental work on the production of penicillin had been going on for at least 3 years at Elberfeld under the direction of Dr. Auhagen. During this time little progress appears to have been made, probably due to concentration by this firm on Marfanil [a sulfonamide antibiotic] and related compounds. In previous reports Auhagen had claimed to have produced penicillin assaying 200 units per mg. and to have obtained 50 units per ml. in broth with surface cultures. [...]

The strain he was using had been locally isolated and had been identified in England as Penicillium bruneo rubrum. [...]

It was intended to freeze dry the purified penicillin in bulk and weigh out into ampoules aseptically.

BIOS 1417. ***Food Preservation with Special Reference to Its Domestic Application.***

2. Plenora-Werke, Neuekampstrasse, Hamburg.

Herr Speck, the Manager, took us round and explained the process very thoroughly. We also spoke to several heads of departments, the laboratory director, and bakery manager. The firm was concerned entirely with the manufacture of a dried egg substitute from blood plasma. The process was started on an experimental scale in 1934, and went into production on a large scale on the outbreak of war in 1939. The factory was almost completely destroyed by bombs but was largely rebuilt in 1943. This was said to be the only factory in the world making this product from blood.

The blood came in from the slaughterhouses, some of which were close by, but a good deal also came from Denmark in casks (aluminium or lacquered) and preserved with ammonia. Every animal was vetted before slaughtering. The blood was first mixed with sodium phosphate or citrate to prevent coagulation, strained, then separated by centrifuging into the red and white fractions. Both parts were then cooled at a temperature of 2^oC. to 4^oC. in a refrigerator. It must not reach freezing point. The blood was stored at this temperature until required. Blood received from any distance was separated into red and white fractions and cooled before transport.

The two fractions were heated separately in an open steam-jacketed pan to remove about 50% of the water. Each part was then dehydrated in a spray-dryer of the type generally used for drying eggs or milk. The dried red fraction was sold for sausage-making[...]

The factory had been producing 5,000 Kg. of "Plenora" per day but could produce ten times that quantity if sufficient raw materials were available.

This process certainly produces a very useful and nutritious substitute for egg from slaughterhouse blood, which is wasted in this country [U.K.] in large quantities.

BIOS 1481. ***Albumen Substitutes from Fish: Further Report on Deutschen Eiweiss Gesellschaft.***

For the production of first grade high protein Eiweiss for medical and culinary purposes fresh skinned fillets of cod and haddock are used. This raw material gives a final product of little taste or smell and of high grade quality and solubility and is said to be better than egg albumen for most purposes where this material was formerly used. [...]

The whole process can be separated into the following stages:

(i) Preparation of raw material

(ii) Initial cooking and washing

(iii) Pressing

(iv) Solvent extraction

(v) Solvent recovery

(vi) Hydrolization (i.e. conversion of insoluble protein into soluble Eiweiss)

and it is therefore proposed to deal with these stages in their respective order. [...]

Johanna Vogel-Prandtl. 2014. *Ludwig Prandtl: A Personal Biography Drawn from Memories and Correspondence.* Göttingen: Universitätsverlag Göttingen. pp. 3–4. http://library.oapen.org/handle/20.500.12657/31848

In the merchant's house in Hauptstraße, Alexander Prandtl [father of Ludwig Prandtl] rented a room from the widow Maria Ostermann as, at the age of 29, he started to work as a university teacher at the central agricultural school in Weihenstephan in Freising. He came from Munich, where he had been to school and then studied. After attending the polytechnic school, he gained the qualification of cultural engineer and obtained an appointment in this capacity with the federal state in Lower Bavaria. He subsequently received an appointment as professor of applied mathematics and amelioration2. In Weihenstephan, the following subjects were also taught: agricultural chemistry, agricultural equipment drawing and botanical drawing, the anatomy and physiology of domestic animals, forestry, meteorology, as well as other subjects. A brewery for study purposes was attached to the institution. Alexander carried out scientific work in the laboratory of the dairy research station. In the period between 1870 and 1875, he mostly worked on the construction of a continuously operating milk centrifuge. The idea of studying the separation of cream from milk using centrifugal force came from his brother Antonin, who had published a work on this subject eleven years previously in the polytechnic journal. He initially approached the practical task of making it possible to concentrate milk using his knowledge of chemistry. Alexander was successful in adding some significant improvements to his brother's discovery and, in 1875, he demonstrated his cream separator at the World's Fair in Frankfurt am Main, Germany. This machine, which was the first continuously operating milk centrifuge in the world, attracted great attention and provided the impulse for further developments. The same model was later exhibited in the *Deutsches Museum* (German Museum), in the Department of Dairy Farming. In the next few years, he developed a new piece of equipment: a milk separator that could be used to produce milk in parts without it creaming. In addition, Alexander published a number of scientific papers in the Weihenstephan Milk Journal, whose themes I would like to mention here for reasons of completeness. In 1877 the article "On the theoretically expected effect of creaming caused by centrifugal forces" and, in 1879, "The effect of currents caused by heating or cooling milk" were published.

Max Hupfauer. 1972. Milchgeräte. *Bayerisches Landwirtschaftliches Jahrbuch* 49:1: 105–124. https://mediatum.ub.tum.de/1554376

Die Erfindung der Zentrifuge wurde mit Recht als die Erlösung der Milchwirtschaft bezeichnet. An ihren Anfang darf man die 1864 von ANTONIN PRANDTL, einem Eleven der Technologischen Abteilung der Weihenstephaner Königlichen Landwirtschaftlichen Zentralschule, gebaute Eimer-Zentrifuge stellen. Ihm folgten WILHELM LEFELDT mit einer auf der Landwirtschaftlichen Weltausstellung in Bremen 1874 gezeigten Eimer-Schleuder. Einen weiteren Impuls erhielt diese Entwicklung wiederum aus Weihenstephan durch den Professor für Landwirtschaft, Dr. ALEXANDER PRANDTL, einem Bruder des vorhin erwähnten, der 1875 eine Milchschleuder konstruiert hatte, welche bereits den Gedanken der ununterbrochenen Entrahmung verwirklichen sollte (Abb. 1). Dieses Ziel erreichte jedoch erst 1878 der schwedische Ingenieur Dr. GUSTAV PATRlK DE LAVAL, welcher durch Veröffentlichungen über LEFELDT's Milchschleuder zu seiner bahnbrechenden Erfindung angeregt worden war (Abb. 2).

Absatzgebiete waren aber nur größere Molkereien, bis es DE LAVAL 1886 gelang, eine Ausführung für Handbetrieb herzustellen. Ausschlaggebend für die weitere Verbreitung wurde 1890 die Erfindung des Münchener Ingenieurs CARL FREIHERR VON BECHTOLSHEIM (Abb. 3), mit deren Hilfe störende Strömungen in der umlaufenden Zentrifugentrommel beseitigt und damit die Stundenleistung, die Entrahmungsschärfe sowie die Ausbeute wesentlich erhöht werden. DE LAVAL erkennt die weittragende Bedeutung dieser Erfindung und kauft das Deutsche Reichspatent Nr. 48 615 für die von ihm inzwischen gegründete Separatorenfabrik in Stockholm auf. Um die Jahrhundertwende hatten bereits mehr als 150 000 Maschinen das Werk verlassen und erst, als am 14. Juli 1903 das ALFA-LAVAL-Patent erlosch, konnten auch andere Fabrikanten gleichwertige Geräte liefern. Über die stürmische Entwicklung der Milchverarbeitung mit Hilfe von Zentrifugen gibt Professor MARTINYS Bericht Auskunft, wonach im Jahre 1907 bei einer Gesamtzahl von 347 649 landwirtschaftlichen Betrieben 336 906 Milchschleudern benutzten und in gewerblichen Betrieben außerdem 10 743 Molkerei-Zentrifugen gezählt wurden. Diese Mechanisierung der Rahmgewinnung war die Grundlage der weithin verbreiteten bäuerlichen Butterherstellung.

The invention of the centrifuge was rightly described as the salvation of the dairy industry. It began with the bucket centrifuge built in 1864 by ANTONIN PRANDTL, a student in the technology department of the Royal Agricultural College in Weihenstephan. He was followed by WILHELM LEFELDT with a bucket centrifuge exhibited at the World Agricultural Exhibition in Bremen in 1874. This development received further impetus from Weihenstephan through the Professor of Agriculture, Dr. ALEXANDER PRANDTL, a brother of the aforementioned, who had constructed a milk centrifuge in 1875, which was already intended to realize the idea of continuous operation (Fig. 1). However, this goal was not achieved until 1878 by the Swedish engineer Dr. GUSTAV PATRlK DE LAVAL, who had been inspired by publications on LEFELDT's milk extractor to make his groundbreaking invention (Fig. 2).

However, only larger dairies sold them until DE LAVAL succeeded in producing a version for manual operation in 1886. In 1890, the invention of the Munich engineer CARL FREIHERR VON BECHTOLSHEIM (Fig. 3) eliminated the disturbing currents in the rotating centrifuge drum, thus significantly increasing the hourly output, the skimming sharpness, and the yield, which was decisive for further distribution. DE LAVAL recognized the far-reaching significance of this invention and bought the German Imperial Patent No. 48,615 for the separator factory he had since founded in Stockholm. By the turn of the century, more than 150,000 machines had already left the factory and it was only when the ALFA-LAVAL patent expired on 14 July 1903 that other manufacturers were able to supply equivalent devices. Professor MARTINY's report provides information on the rapid development of milk processing with the aid of centrifuges, according to which in 1907 336,906 milk centrifuges were used on a total of 347,649 farms and 10,743 dairy centrifuges were also counted on commercial farms. This mechanization of cream production was the basis of widespread farm butter production.

APPENDIX 2

TRANSLATION

THE PHYWE Ultracentrifuge

Physikalische Werkstatten A.G. Göttingen (Hann.)

Development of the Ultracentrifuge

In 1923, The Svedberg and J. B. Nichols built a centrifuge in which optical observation of the sedimentation of dissolved particles was possible during the rotation. [...]

Characteristics of the PHYWE Ultracentrifuge

Phywe A.G., Göttingen, and G. Schramm (Kaiser Wilhelm Institut für Biochemie, Berlin-Dahlem) developed jointly an ultracentrifuge, with air drive, which is simple to operate and within the means of every laboratory, but which, nevertheless, possesses a sufficiently high separating power. The choice of an air drive, in conjunction with a special damping device, ensured smooth running of the centrifuge. In its simplest form, the Phywe ultracentrifuge is suitable for preparative work. It can, however, also be fitted with a second rotor for optical observation and hence for analytical work. The optical method adopted is the "schlieren" method, but the apparatus is constructed so that the scale method can also be used. [...]

General Considerations on Measurements with the Ultracentrifuge

The ultracentrifuge is one of the most important instruments for the investigation of high molecular or colloidal substances. The field of application lies in the region where most chemical and physical methods of separation and characterisation of the substances fail. The ultracentrifuge serves for the determination of the size and the homogeneity of a molecular species. For this purpose two methods are used: (1) Determination of the sedimentation velocity, (2) the sedimentation equilibrium. [...]

Applications of the Ultracentrifuge

The ultracentrifuge can be used for the investigation of the most varied range of substances. Doubtless the greatest successes have been obtained in the field of the proteins, but promising work has also been done in the case of the carbohydrates, polystyrols, and similar organic products, inorganic colloids and inorganic salts.

The work on the proteins has shown that the naturally occurring proteins are, in respect of molecular weight, always homogeneous substances. Even complex systems such as serum (References 9 and 10) or milk proteins (Reference 11) can be analysed with the aid of the ultracentrifuge. They are always resolved into a limited number of homogeneous components. Systematic investigations of the proteins from different species have led to interesting genetical relations. In the examination of enzymes, sera and antibodies, snake venom and other physiologically active proteins, the ultracentrifuge has strikingly proved its value (Reference 3). The newer developments in the field of virus proteins and bacteriophages would be inconceivable without the ultracentrifuge. (For the application of the ultracentrifuge in virus research see Reference 12). [...]

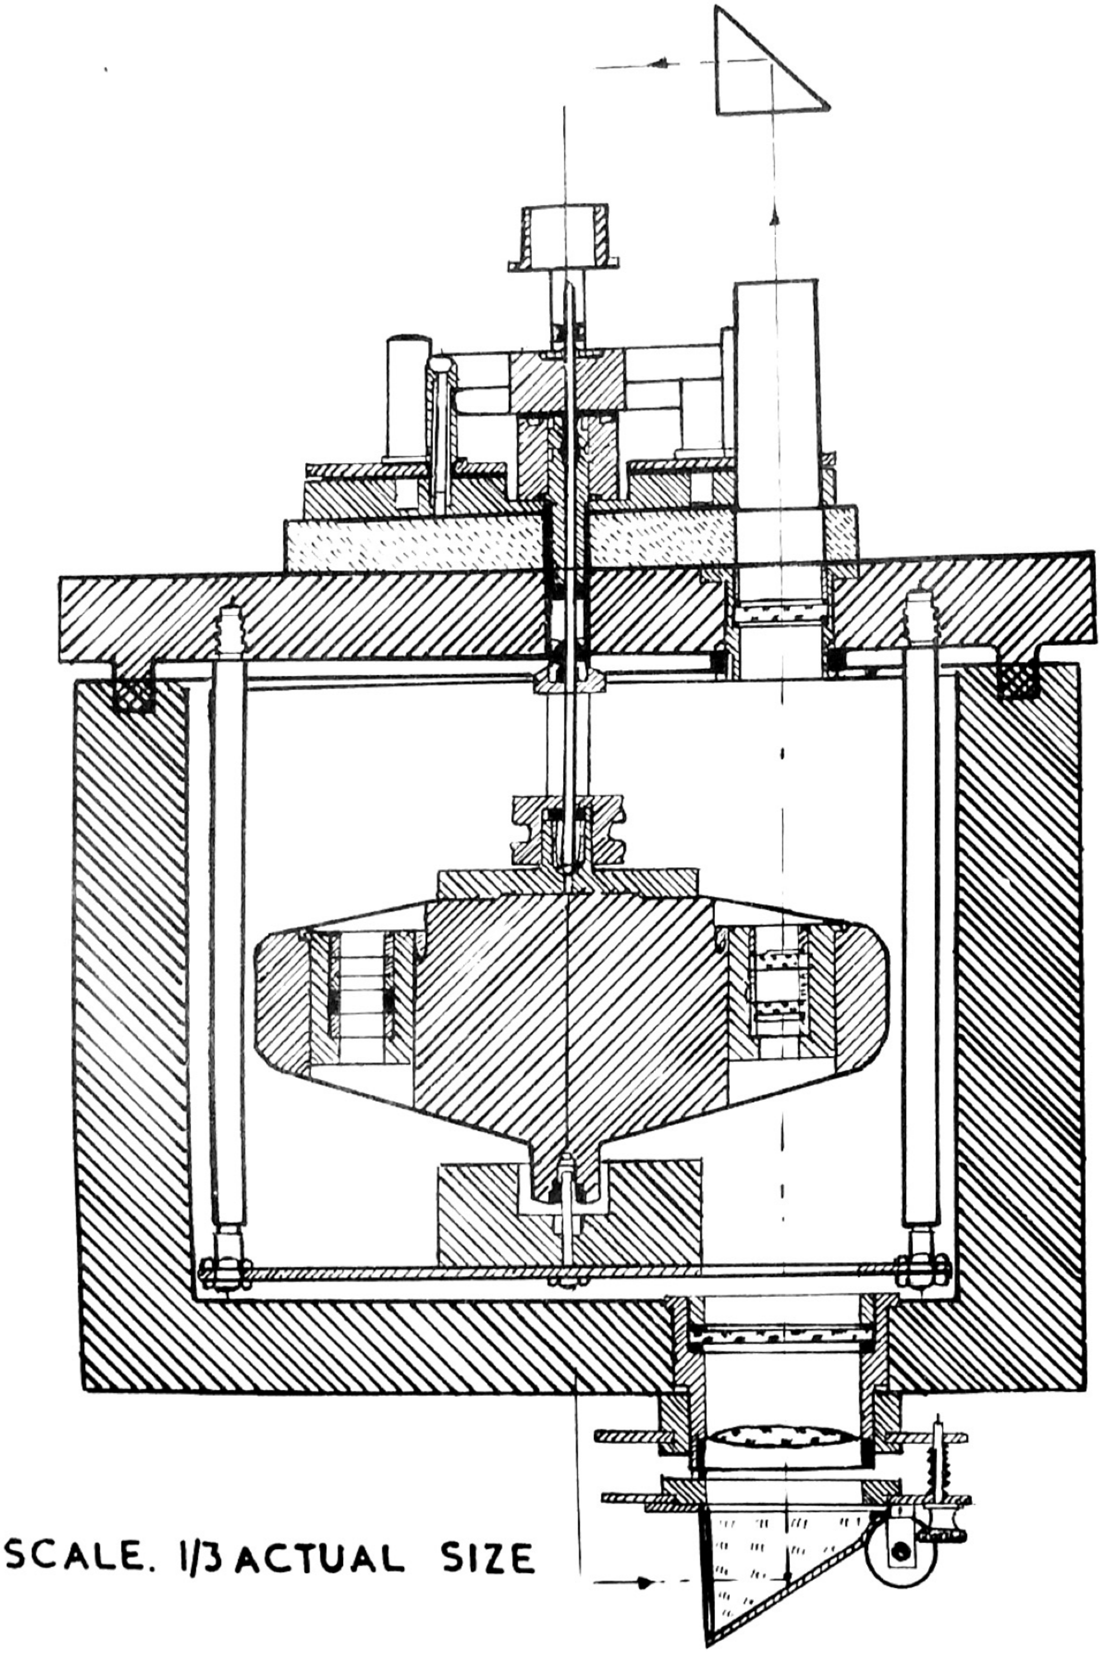
[Centrifuges for milk separation and other applications were first developed in the German-speaking world, beginning no later than 1864 (pp. 2394–2396).

The ultracentrifuge described in BIOS 1487 was one of several that were developed by Gerhard Schramm for his groundbreaking research on viruses and proteins.

Ultracentrifuges are now extensively used in biology and chemistry laboratories worldwide.

The next page shows a diagram of the ultracentrifuge from BIOS 1487.]



SCALE. 1/3 ACTUAL SIZE

Figure A.63: Ultracentrifuge developed by Gerhard Schramm and collaborators beginning in the 1930s [BIOS 1487].

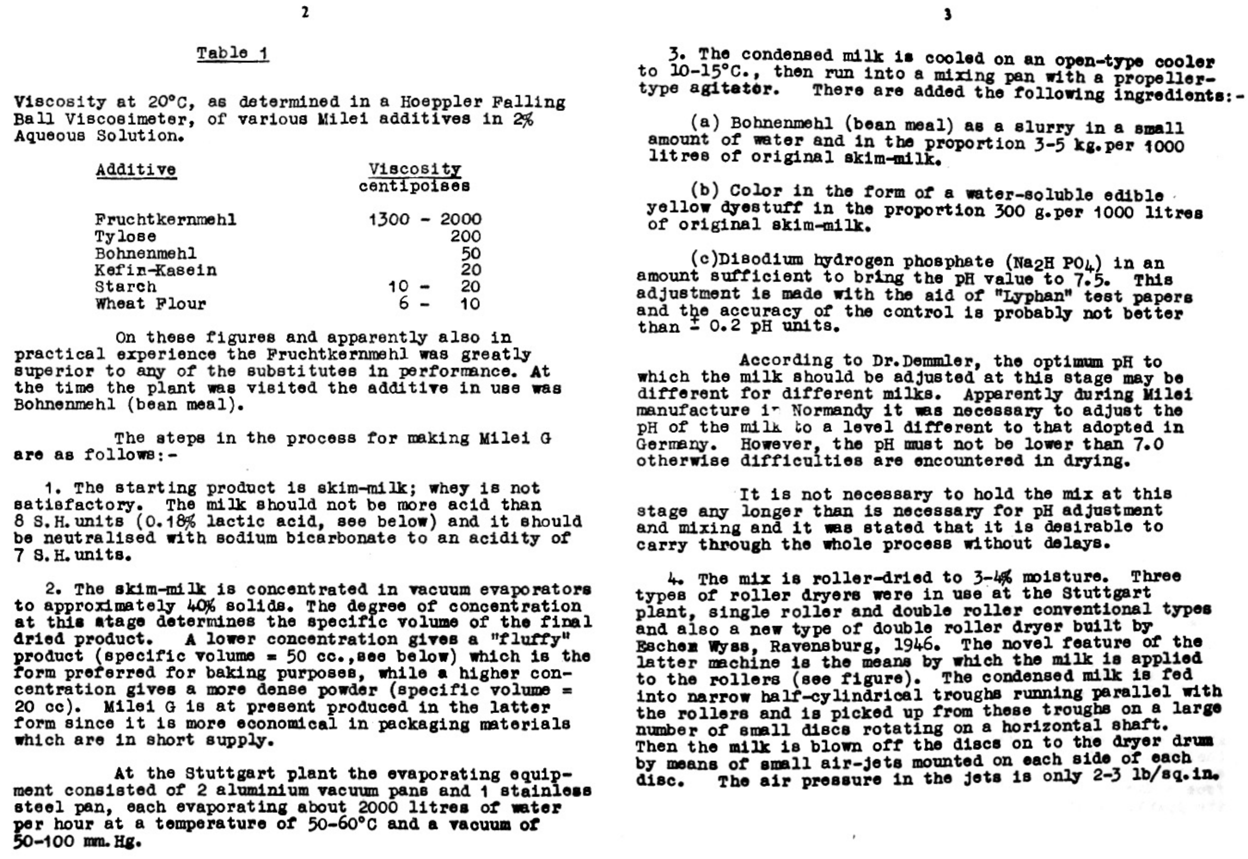


Table 1

Viscosity at 20°C, as determined in a Hoeppler Falling Ball Viscosimeter, of various Milei additives in 2% Aqueous Solution.

Additive	Viscosity centipoises
Fruchtkernmehl	1300 - 2000
Tylose	200
Bohnenmehl	50
Kefin-Kasein	20
Starch	10 - 20
Wheat Flour	6 - 10

On these figures and apparently also in practical experience the Fruchtkernmehl was greatly superior to any of the substitutes in performance. At the time the plant was visited the additive in use was Bohnenmehl (bean meal).

The steps in the process for making Milei G are as follows:-

1. The starting product is skim-milk; whey is not satisfactory. The milk should not be more acid than 8 S.H. units (0.18% lactic acid, see below) and it should be neutralised with sodium bicarbonate to an acidity of 7 S.H. units.

2. The skim-milk is concentrated in vacuum evaporators to approximately 40% solids. The degree of concentration at this stage determines the specific volume of the final dried product. A lower concentration gives a "fluffy" product (specific volume = 50 cc., see below) which is the form preferred for baking purposes, while a higher concentration gives a more dense powder (specific volume = 20 cc). Milei G is at present produced in the latter form since it is more economical in packaging materials which are in short supply.

At the Stuttgart plant the evaporating equipment consisted of 2 aluminium vacuum pans and 1 stainless steel pan, each evaporating about 2000 litres of water per hour at a temperature of 50-60°C and a vacuum of 50-100 mm. Hg.

3. The condensed milk is cooled on an open-type cooler to 10-15°C., then run into a mixing pan with a propeller-type agitator. There are added the following ingredients:-

(a) Bohnenmehl (bean meal) as a slurry in a small amount of water and in the proportion 3-5 kg. per 1000 litres of original skim-milk.

(b) Color in the form of a water-soluble edible yellow dyestuff in the proportion 300 g. per 1000 litres of original skim-milk.

(c) Disodium hydrogen phosphate ($Na_2H\ PO_4$) in an amount sufficient to bring the pH value to 7.5. This adjustment is made with the aid of "Lyphan" test papers and the accuracy of the control is probably not better than ± 0.2 pH units.

According to Dr. Demmler, the optimum pH to which the milk should be adjusted at this stage may be different for different milks. Apparently during Milei manufacture in Normandy it was necessary to adjust the pH of the milk to a level different to that adopted in Germany. However, the pH must not be lower than 7.0 otherwise difficulties are encountered in drying.

It is not necessary to hold the mix at this stage any longer than is necessary for pH adjustment and mixing and it was stated that it is desirable to carry through the whole process without delays.

4. The mix is roller-dried to 3-4% moisture. Three types of roller dryers were in use at the Stuttgart plant, single roller and double roller conventional types and also a new type of double roller dryer built by Escher Wyss, Ravensburg, 1946. The novel feature of the latter machine is the means by which the milk is applied to the rollers (see figure). The condensed milk is fed into narrow half-cylindrical troughs running parallel with the rollers and is picked up from these troughs on a large number of small discs rotating on a horizontal shaft. Then the milk is blown off the discs on to the dryer drum by means of small air-jets mounted on each side of each disc. The air pressure in the jets is only 2-3 lb/sq.in.

BIOS 1513. ***The Manufacture of "Milei" Egg Substitutes.***

Milei G (gelb) is an egg-yolk or whole-egg substitute which is described as having the binding properties of egg in bakery products and household cooking. To some extent these binding properties are due to a vegetable constituent which is added. [...]

Milei W (Weiss) is an egg-white substitute which has the whipping properties of egg-white and is used mainly for meringue-type bakery products. [...]

[See the figure from this report on the preceding page.]

BIOS 1776. ***Yeast and Citric Acid Production from Sugar Beet Molasses in Germany.***

The following report deals with only two aspects of the industrial utilization of beet molasses, namely the manufacture of yeast and citric acid. Yeast production is a relatively old and well-established industry, hence only the processes used by one of the largest German firms in the field were examined. In contrast to the yeast industry, fermentation citric acid production is of more recent origin and only became established in Germany during the war. The first plant operated by C. H. Boehringer Sohn, Ingelheim on the Rhine, started production in 1938–1939. Another entirely independent company, the Chemische Fabrik J. A. Benkiser at Ladenburg, near Heidelberg, planned erection of a new fermentation citric acid plant in the same year. This plant was built during the war but did not get into production until January, 1945. Both companies had been familiar with the chemical manufacture of citric acid for many years, importing calcium citrate as the raw material. Research was carried out on the fermentation process and its results, combined with industrial experience from Czechoslovakia, enabled each company to develop its own process. Contrary to the history of most citric acid producers in other countries, both of the German plants were built for the use of sugar beet molasses as a raw material and neither have operated with sugar in various stages of refining.

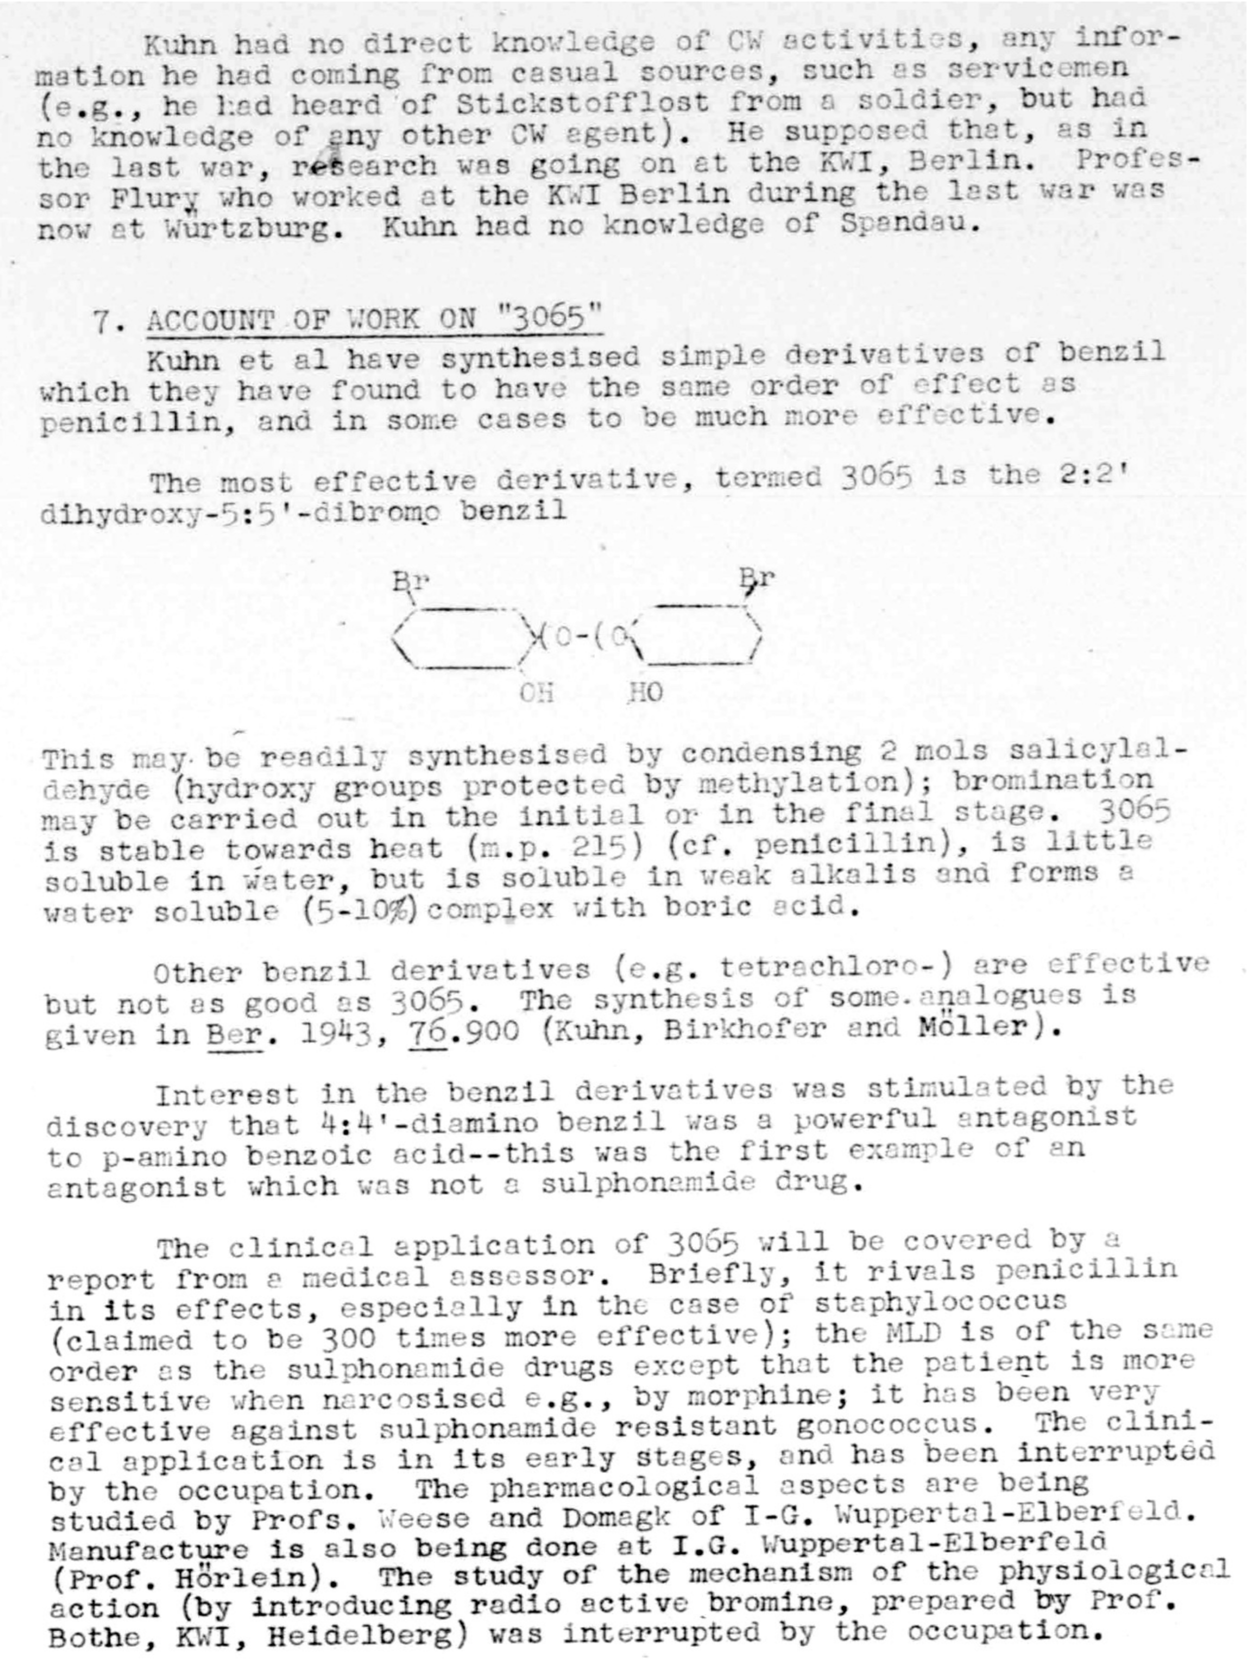
CIOS ER 1. ***Professor R. Kuhn at the KWI, Heidelberg.***

[Please see p. 2406.]

CIOS ER 10. ***K.W.I. für Medizinische Forschung, Heidelberg.***

[Please see pp. 2407–2411.]



Kuhn had no direct knowledge of CW activities, any information he had coming from casual sources, such as servicemen (e.g., he had heard of Stickstofflost from a soldier, but had no knowledge of any other CW agent). He supposed that, as in the last war, research was going on at the KWI, Berlin. Professor Flury who worked at the KWI Berlin during the last war was now at Würtzburg. Kuhn had no knowledge of Spandau.

7. ACCOUNT OF WORK ON "3065"

Kuhn et al have synthesised simple derivatives of benzil which they have found to have the same order of effect as penicillin, and in some cases to be much more effective.

The most effective derivative, termed 3065 is the 2:2' dihydroxy-5:5'-dibromo benzil

This may be readily synthesised by condensing 2 mols salicylaldehyde (hydroxy groups protected by methylation); bromination may be carried out in the initial or in the final stage. 3065 is stable towards heat (m.p. 215) (cf. penicillin), is little soluble in water, but is soluble in weak alkalis and forms a water soluble (5-10%) complex with boric acid.

Other benzil derivatives (e.g. tetrachloro-) are effective but not as good as 3065. The synthesis of some analogues is given in Ber. 1943, 76.900 (Kuhn, Birkhofer and Möller).

Interest in the benzil derivatives was stimulated by the discovery that 4:4'-diamino benzil was a powerful antagonist to p-amino benzoic acid--this was the first example of an antagonist which was not a sulphonamide drug.

The clinical application of 3065 will be covered by a report from a medical assessor. Briefly, it rivals penicillin in its effects, especially in the case of staphylococcus (claimed to be 300 times more effective); the MLD is of the same order as the sulphonamide drugs except that the patient is more sensitive when narcosised e.g., by morphine; it has been very effective against sulphonamide resistant gonococcus. The clinical application is in its early stages, and has been interrupted by the occupation. The pharmacological aspects are being studied by Profs. Weese and Domagk of I-G. Wuppertal-Elberfeld. Manufacture is also being done at I.G. Wuppertal-Elberfeld (Prof. Hörlein). The study of the mechanism of the physiological action (by introducing radio active bromine, prepared by Prof. Bothe, KWI, Heidelberg) was interrupted by the occupation.

Evaluation Report 10
2 May 1945

COMBINED INTELLIGENCE OBJECTIVES SUB-COMMITTEE

Target No's. 8/58 & 24/17a

KO-10307

1. Full Title of Target: K.W.I. für Medizinische Forschung, Heidelberg.

2. Condition of Target: Undamaged.

3. Description

This target was first assessed and reported upon by a CAFT assessor (Major Adamson) on 11 Apr. 45. (Evaluation Report 1) The present further assessment was carried out in response to cable received 22 Apr. 45 from CIOS which requested:

1. Large samples (up to 5 kilos) of '3065' and cyclodecane pentaene $C_{10}H_{10}$.

2. Dispatch of clinical report on 3065 to CIOS.

MAY 16 '45 PM

The following is now recorded:

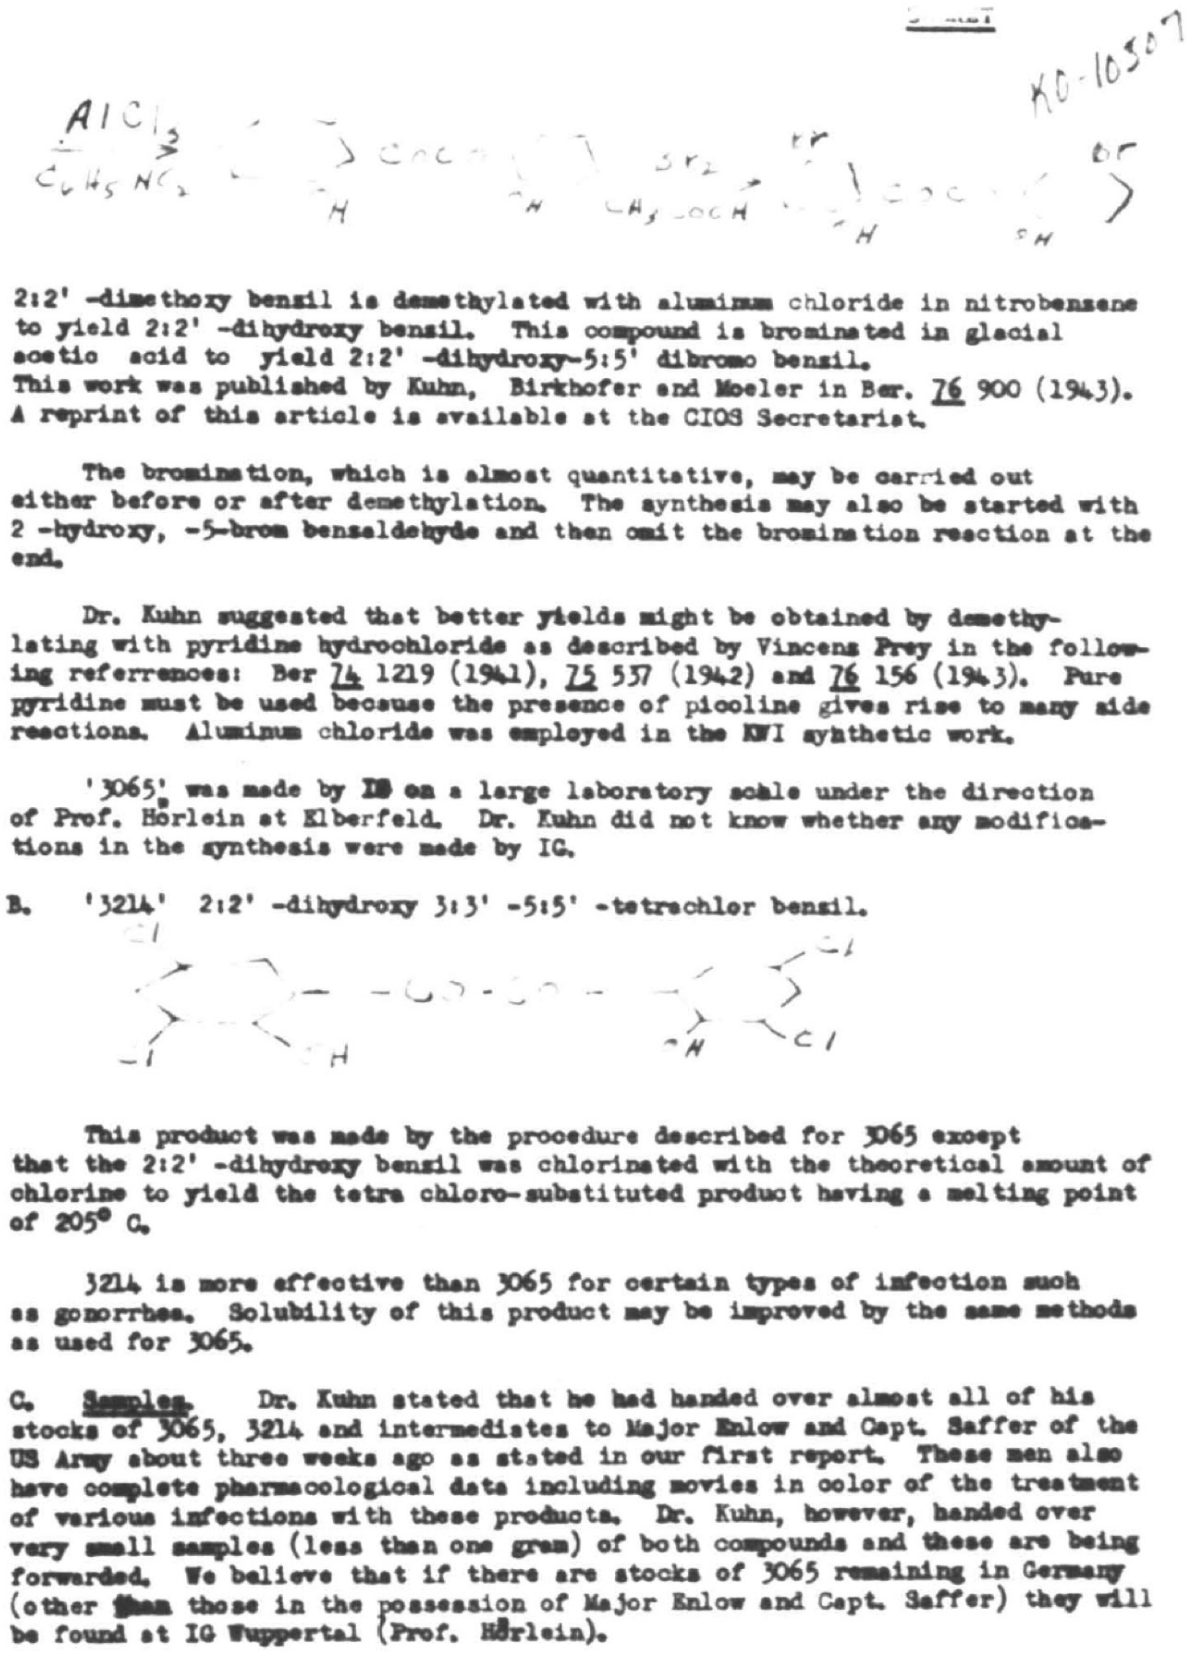
A. Further details on synthesis of 3065.
B. Synthesis of 3214 (an analogue of 3065).
C. Position with regard to samples.
D. Clinical report.
E. Further information on cyclodecane pentaene.

A. Synthesis of '3065', 2:2' - dihydroxy - 5:5' - dibromo benzil

Prof. Kuhn did not have a detailed description of the synthesis of 3065. The preparation of 2:2' - dihydroxy benzil is described in the literature and was prepared at KWI according to the published method. The remainder of the synthesis was worked out under Kuhn and is described in one of his publications (Ber. 76 900, (1943)). An outline of the procedure is as follows:

Salicylaldehyde + dimethyl sulfate — o-methoxy benzaldehyde
o-methoxy benzaldehyde - KCN in ethyl alcohol - 2:2'-dimethoxy benzoin
2:2' -dimethoxy benzoin is oxidised with alcoholic Fehling's solution to yield 2:2'-dimethoxy benzil.
These methods are described in an article by Schönberg and Kraemer Ber. 55 1184 (1922) and by J.C. Irvine J.C.S. 79 670 (1901)

Figure A.69: Richard Kuhn developed a synthetic antibiotic dubbed “3065” [CIOS ER 10].



KO-10507

AlCl3
C6H5NO2
Br2
CH3COOH

2:2' -dimethoxy benzil is demethylated with aluminum chloride in nitrobenzene to yield 2:2' -dihydroxy benzil. This compound is brominated in glacial acetic acid to yield 2:2' -dihydroxy-5:5' dibromo benzil. This work was published by Kuhn, Birkhofer and Moeler in Ber. 76 900 (1943). A reprint of this article is available at the CIOS Secretariat.

The bromination, which is almost quantitative, may be carried out either before or after demethylation. The synthesis may also be started with 2 -hydroxy, -5-brom benzaldehyde and then omit the bromination reaction at the end.

Dr. Kuhn suggested that better yields might be obtained by demethylating with pyridine hydrochloride as described by Vincenz Prey in the following referrences: Ber 74 1219 (1941), 75 537 (1942) and 76 156 (1943). Pure pyridine must be used because the presence of picoline gives rise to many side reactions. Aluminum chloride was employed in the KWI synthetic work.

'3065' was made by IG on a large laboratory scale under the direction of Prof. Hörlein at Elberfeld. Dr. Kuhn did not know whether any modifications in the synthesis were made by IG.

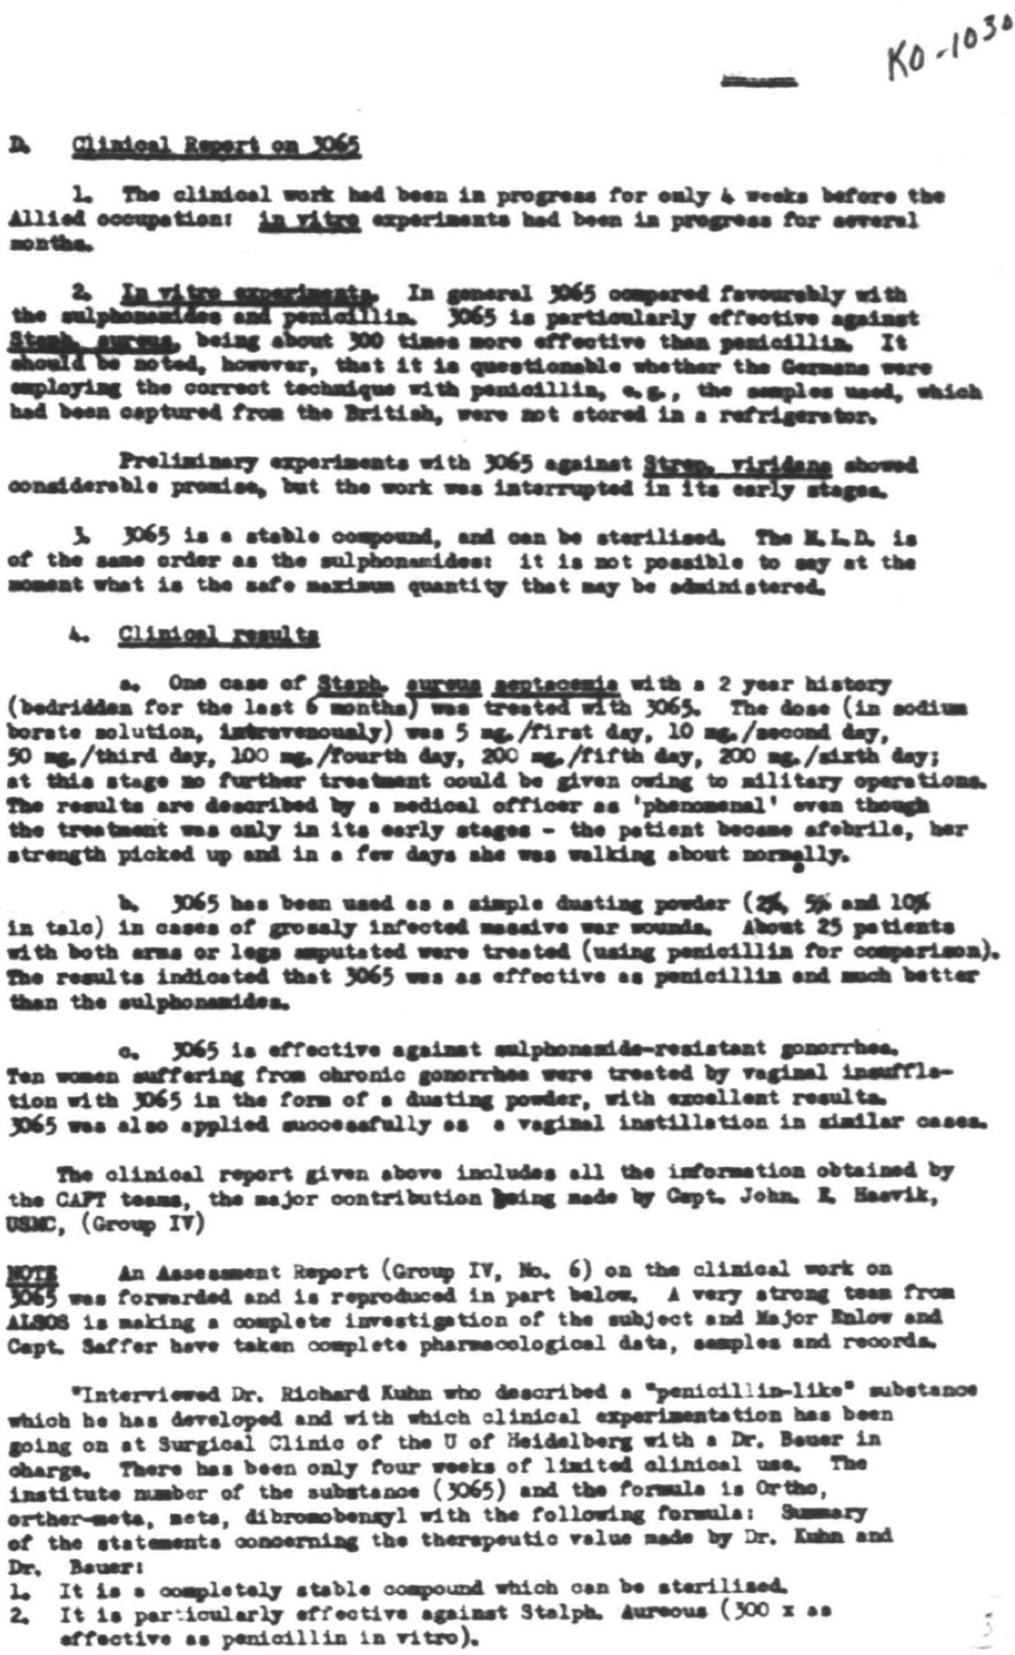
B. '3214' 2:2' -dihydroxy 3:3' -5:5' -tetrachlor benzil.

This product was made by the procedure described for 3065 except that the 2:2' -dihydroxy benzil was chlorinated with the theoretical amount of chlorine to yield the tetra chloro-substituted product having a melting point of 205° C.

3214 is more effective than 3065 for certain types of infection such as gonorrhea. Solubility of this product may be improved by the same methods as used for 3065.

C. Samples. Dr. Kuhn stated that he had handed over almost all of his stocks of 3065, 3214 and intermediates to Major Enlow and Capt. Saffer of the US Army about three weeks ago as stated in our first report. These men also have complete pharmacological data including movies in color of the treatment of various infections with these products. Dr. Kuhn, however, handed over very small samples (less than one gram) of both compounds and these are being forwarded. We believe that if there are stocks of 3065 remaining in Germany (other than those in the possession of Major Enlow and Capt. Saffer) they will be found at IG Wuppertal (Prof. Hörlein).

Figure A.70: Richard Kuhn developed a synthetic antibiotic dubbed “3065” [CIOS ER 10].



KO-10307

D. Clinical Report on 3065

1. The clinical work had been in progress for only 4 weeks before the Allied occupation: in vitro experiments had been in progress for several months.

2. In vitro experiments. In general 3065 compared favourably with the sulphonamides and penicillin. 3065 is particularly effective against Staph. aureus, being about 300 times more effective than penicillin. It should be noted, however, that it is questionable whether the Germans were employing the correct technique with penicillin, e.g., the samples used, which had been captured from the British, were not stored in a refrigerator.

Preliminary experiments with 3065 against Strep. viridans showed considerable promise, but the work was interrupted in its early stages.

3. 3065 is a stable compound, and can be sterilised. The M.L.D. is of the same order as the sulphonamides: it is not possible to say at the moment what is the safe maximum quantity that may be administered.

4. Clinical results

a. One case of Staph. aureus septacemia with a 2 year history (bedridden for the last 6 months) was treated with 3065. The dose (in sodium borate solution, intravenously) was 5 mg./first day, 10 mg./second day, 50 mg./third day, 100 mg./fourth day, 200 mg./fifth day, 200 mg./sixth day; at this stage no further treatment could be given owing to military operations. The results are described by a medical officer as 'phenomenal' even though the treatment was only in its early stages - the patient became afebrile, her strength picked up and in a few days she was walking about normally.

b. 3065 has been used as a simple dusting powder (2%, 5% and 10% in talc) in cases of grossly infected massive war wounds. About 25 patients with both arms or legs amputated were treated (using penicillin for comparison). The results indicated that 3065 was as effective as penicillin and much better than the sulphonamides.

c. 3065 is effective against sulphonamide-resistant gonorrhea. Ten women suffering from chronic gonorrhea were treated by vaginal insufflation with 3065 in the form of a dusting powder, with excellent results. 3065 was also applied successfully as a vaginal instillation in similar cases.

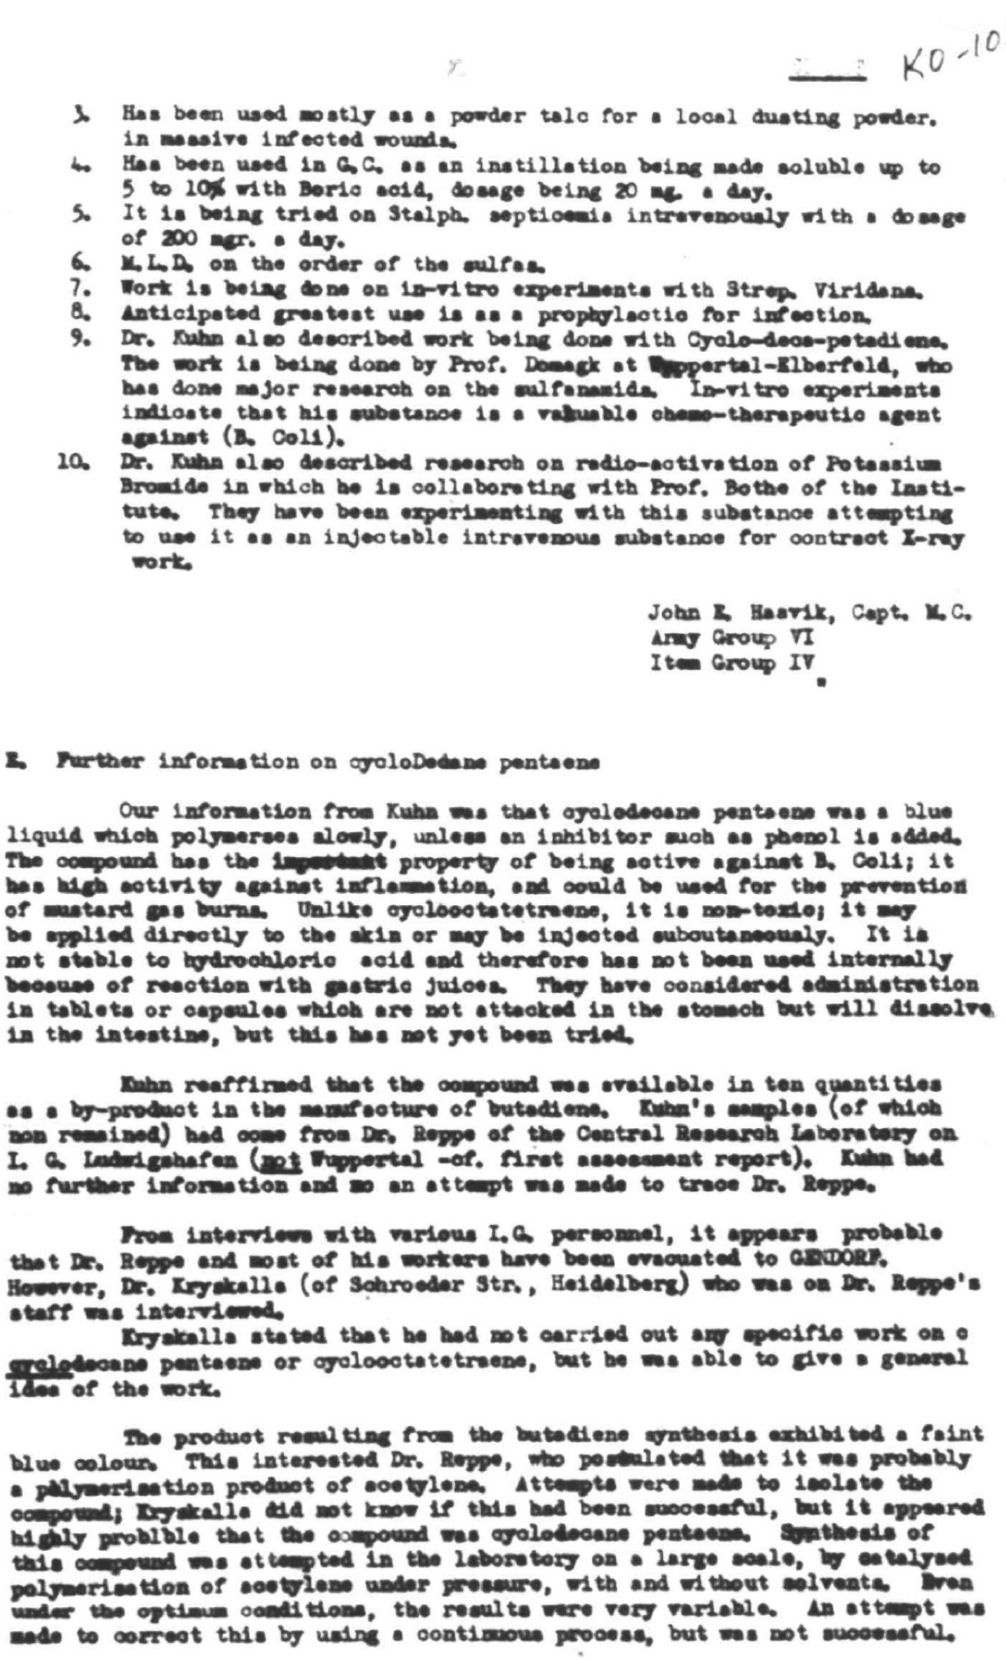
The clinical report given above includes all the information obtained by the CAFT teams, the major contribution being made by Capt. John. R. Haavik, USMC, (Group IV)

NOTE An Assessment Report (Group IV, No. 6) on the clinical work on 3065 was forwarded and is reproduced in part below. A very strong team from ALSOS is making a complete investigation of the subject and Major Enlow and Capt. Saffer have taken complete pharmacological data, samples and records.

"Interviewed Dr. Richard Kuhn who described a "penicillin-like" substance which he has developed and with which clinical experimentation has been going on at Surgical Clinic of the U of Heidelberg with a Dr. Bauer in charge. There has been only four weeks of limited clinical use. The institute number of the substance (3065) and the formula is Ortho, orther-meta, meta, dibromobenzyl with the following formula: Summary of the statements concerning the therapeutic value made by Dr. Kuhn and Dr. Bauer:

1. It is a completely stable compound which can be sterilised.
2. It is particularly effective against Stalph. Aureous (300 x as effective as penicillin in vitro).

Figure A.71: Richard Kuhn developed a synthetic antibiotic dubbed "3065" [CIOS ER 10].



KO-10307

3. Has been used mostly as a powder talc for a local dusting powder. in massive infected wounds.
4. Has been used in G.C. as an instillation being made soluble up to 5 to 10% with Boric acid, dosage being 20 mg. a day.
5. It is being tried on Stalph. septicemia intravenously with a dosage of 200 mgr. a day.
6. M.L.D. on the order of the sulfas.
7. Work is being done on in-vitro experiments with Strep. Viridans.
8. Anticipated greatest use is as a prophylactic for infection.
9. Dr. Kuhn also described work being done with Cyclo-deca-petadiene. The work is being done by Prof. Domagk at Wuppertal-Elberfeld, who has done major research on the sulfanamida. In-vitro experiments indicate that his substance is a valuable chemo-therapeutic agent against (B. Coli).
10. Dr. Kuhn also described research on radio-activation of Potassium Bromide in which he is collaborating with Prof. Bothe of the Institute. They have been experimenting with this substance attempting to use it as an injectable intravenous substance for contrast X-ray work.

John E. Haavik, Capt. M.C.
Army Group VI
Item Group IV

E. Further information on cycloDedane pentaene

Our information from Kuhn was that cyclodecane pentaene was a blue liquid which polymerses slowly, unless an inhibitor such as phenol is added. The compound has the important property of being active against B. Coli; it has high activity against inflammation, and could be used for the prevention of mustard gas burns. Unlike cyclooctatetraene, it is non-toxic; it may be applied directly to the skin or may be injected subcutaneously. It is not stable to hydrochloric acid and therefore has not been used internally because of reaction with gastric juices. They have considered administration in tablets or capsules which are not attacked in the stomach but will dissolve in the intestine, but this has not yet been tried.

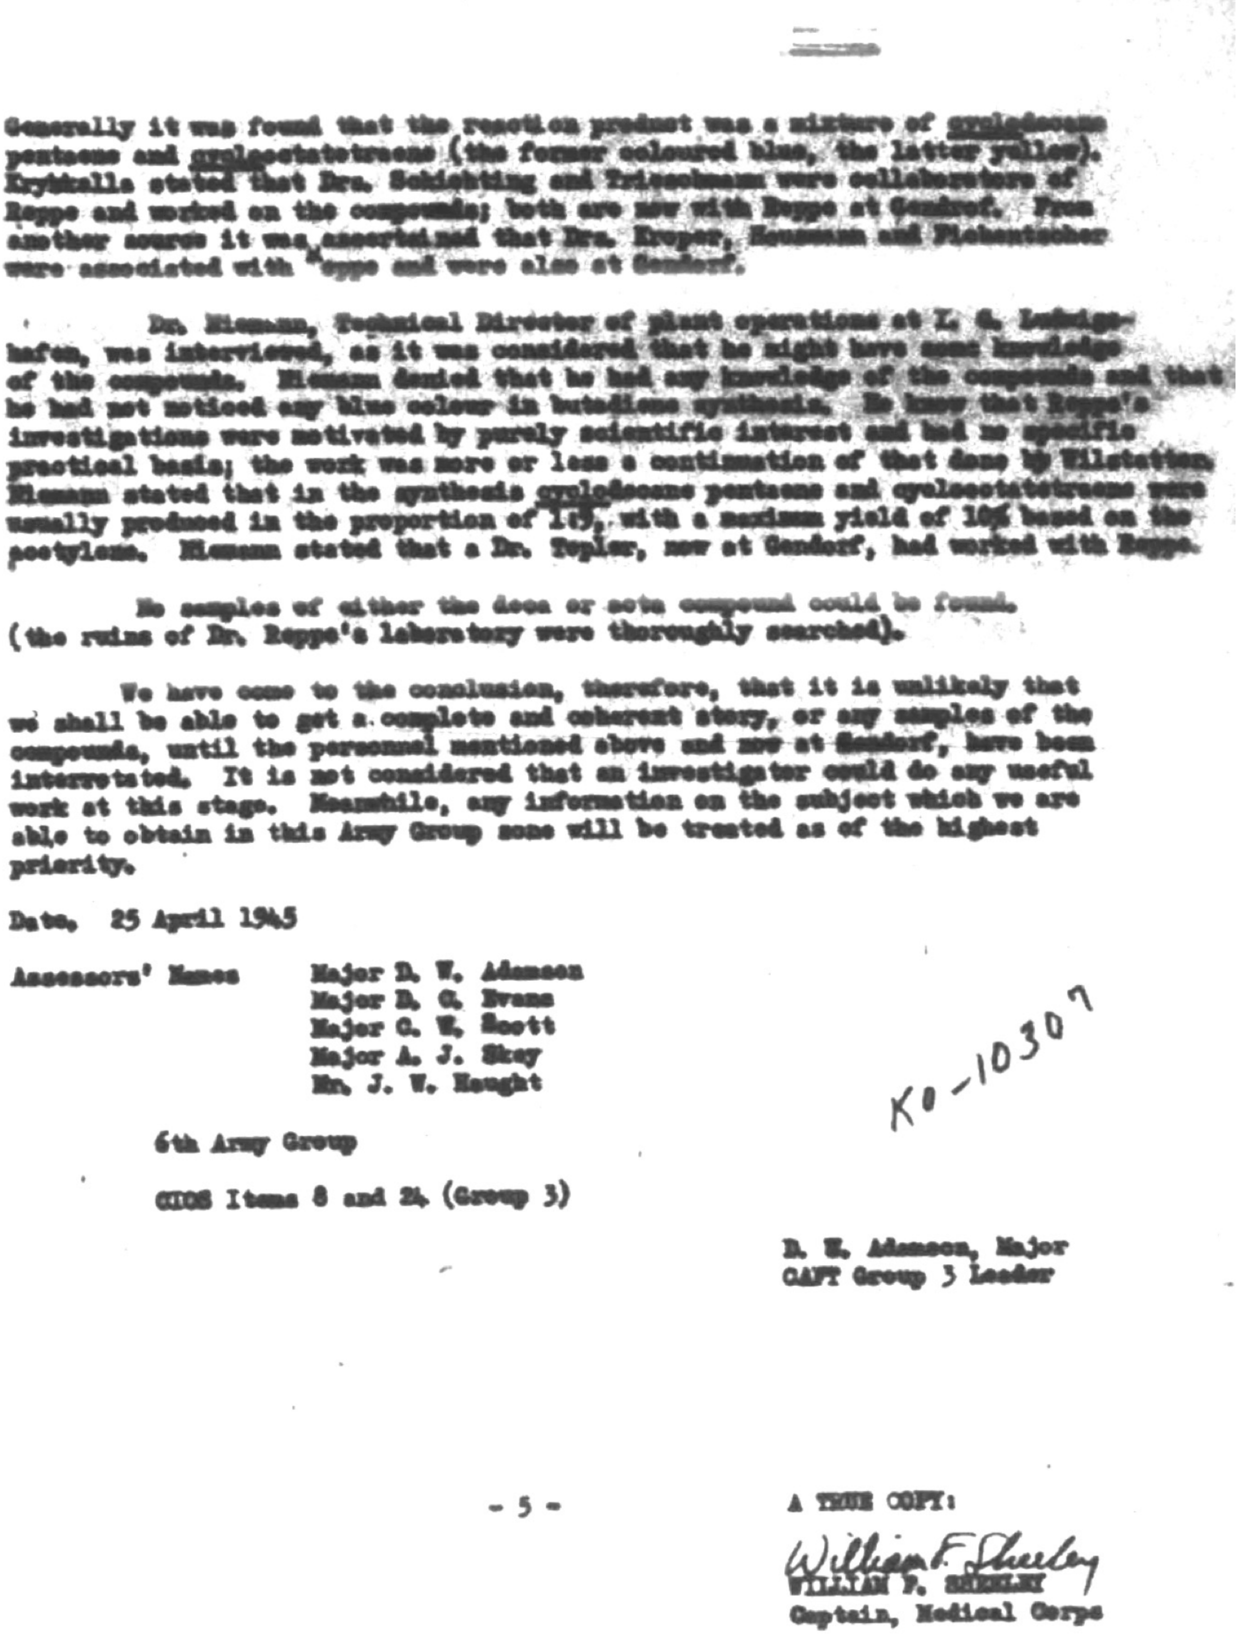
Kuhn reaffirmed that the compound was available in ten quantities as a by-product in the manufacture of butadiene. Kuhn's samples (of which non remained) had come from Dr. Reppe of the Central Research Laboratory on I. G. Ludwigshafen (not Wuppertal -cf. first assessment report). Kuhn had no further information and so an attempt was made to trace Dr. Reppe.

From interviews with various I.G. personnel, it appears probable that Dr. Reppe and most of his workers have been evacuated to GENDORF. However, Dr. Kryskalle (of Schroeder Str., Heidelberg) who was on Dr. Reppe's staff was interviewed.

Kryskalle stated that he had not carried out any specific work on c cyclodecane pentaene or cyclooctatetraene, but he was able to give a general idea of the work.

The product resulting from the butadiene synthesis exhibited a faint blue colour. This interested Dr. Reppe, who postulated that it was probably a polymerisation product of acetylene. Attempts were made to isolate the compound; Kryskalle did not know if this had been successful, but it appeared highly problble that the compound was cyclodecane pentaene. Synthesis of this compound was attempted in the laboratory on a large scale, by catalysed polymerisation of acetylene under pressure, with and without solvents. Even under the optimum conditions, the results were very variable. An attempt was made to correct this by using a continuous process, but was not successful.

Figure A.72: Richard Kuhn developed a synthetic antibiotic dubbed “3065” [CIOS ER 10].



Generally it was found that the reaction product was a mixture of cyclodecane pentaene and cyclooctatetraene (the former coloured blue, the latter yellow). Krybkalla stated that Drs. Schlichting and Triesohmann were collaborators of Reppe and worked on the compounds; both are now with Reppe at Gendorf. From another source it was ascertained that Drs. Kroper, Neumann and Pichentscher were associated with Reppe and were also at Gendorf.

Dr. Niemann, Technical Director of plant operations at I. G. Ludwigshafen, was interviewed, as it was considered that he might have some knowledge of the compounds. Niemann denied that he had any knowledge of the compounds and that he had not noticed any blue colour in butadiene synthesis. He knew that Reppe's investigations were motivated by purely scientific interest and had no specific practical basis; the work was more or less a continuation of that done by Willstatter. Niemann stated that in the synthesis cyclodecane pentaene and cyclooctatetraene were usually produced in the proportion of 1:3, with a maximum yield of 10% based on the acetylene. Niemann stated that a Dr. Topler, now at Gendorf, had worked with Reppe.

No samples of either the deca or octa compound could be found. (the ruins of Dr. Reppe's laboratory were thoroughly searched).

We have come to the conclusion, therefore, that it is unlikely that we shall be able to get a complete and coherent story, or any samples of the compounds, until the personnel mentioned above and now at Gendorf, have been interrotated. It is not considered that an investigator could do any useful work at this stage. Meanwhile, any information on the subject which we are able to obtain in this Army Group zone will be treated as of the highest priority.

CIOS XXIV-16. *Pharmaceutical Targets in Southern Germany.*

[See Fig. A.74.]

CIOS XXV-54. *Pharmaceuticals at I.G. Farbenindustrie Plant Elberfeld*

[This report contains great examples of structure-activity relationship (SAR) testing and optimization with drug molecules such as antibiotics and antimalarials. It also provides a good description of periston. See Figs. A.75–A.90.]

FIAT 195. *Yeast and Nutrition Targets in Germany.* pp. 2, 4.

The targets concerned with growth of food yeast on wood sugars were those visited at the I.G. Farbenindustrie (Bitterfeld), the I.G. Farbenindustrie Film Fabrik (Wolfen) and the Phrix, A.G. (Hamburg). The first mentioned plant contained novel circulating aeration columns for keeping down foaming which was of paramount importance when sulfite waste liquors were used. The latter two plans also employed a foam-minimizing fermentation tank design. The large centrifugal basket-type centrifuges use by the Wolfen plant for separation and washing of the yeast may have application in the U.S. if larger production is anticipated. Most of the wood sugar yeast plants plasmolyzed the cells by heating the pressed yeast with steam. This operation contributed somewhat to an improvement in flavor as well as assured a non-viable product. The I.G. Farbenindustrie plants used a strain of Candidia arborea and the Phrix plant claimed to use Torula utilis. Both types ferment pentoses as well as hexoses. [...]

The research institutes visited included the Universities of Leipzig, Halle, Tübingen, and Kaiser Wilhelm Institute (Heidelberg and Dortmund). The writer was impressed with the freedom the research workers were given. Pure research studies were allowed to proceed practically unmolested. During the first few years of the war some of the younger men were drafted for Army service, but even in the last months of the war many of these were being returned to their laboratories.

[...] The German scientists, such as Kuhn, Butenandt, Aberhalden, Scheunert, certainly reflect the vigorous scientific training characteristic of the German universities and serve to emphasize the high level of achievement in their respective fields. It is noteworthy that the Army research program left such men unmolested to continue their respective peace-time researches.

Schering Research Projects

The principal fields which interested the Schering Company during the war were as follows:

(a) Hormones

Schering A.G. had been using dehydroandrosterone (ex cholesterol) as the starting material for the manufacture of corticosterone, testosterone and progesterone. In collaboration with Dr. Inhoffen, a process for the production of estrone from the same starting material had been developed since 1939, and this synthetic route had completely replaced the production from pregnant mare's urine, of which Schering formerly used 30,000 - 50,000 litres per year. In 1944, fifteen kilos of estrone had been made by the synthetic route. The process is as follows:

Dehydroandrosterone (1), is monobrominated and hydrogen bromide then removed to yield the diene (2). Methane is then split off by passing over a catalyst. The substance (2) is sublimed in a stream of an indifferent vapour (e.g. cyclohexane) over a catalyst (nickel or Raney nickel, etc.) at 500-600°C. This is done in an electrically wound glass tube, and a very short contact time is essential.

(b) Sulpha Drugs

The only new sulpha drugs brought out by Schering during the war years were stated to be Pyrimal (=Sulphadiazine), and Globucid (formula below).

Schering had filed a patent application in 1939, in Germany, Sweden and Switzerland, which covered the sulpha derivatives of amines derived from the following ring systems:

with two ring nitrogens, but Dr. Schoeller was unable to remember which particular isomer (other than the 3:4-diazine) had been covered.

Dr. Schoeller stated that Globucid had an unpleasant taste and he considered it to be less effective than sulphadiazine. It was marketed, however, because of its greater ease of manufacture. He was unable to recall the manufacturing process employed. The higher homologues of Globucid (i.e. ethyl replaced by isopropyl, butyl, etc.) were more effective with increasing chain length, and had less taste, but a higher homologue has not yet been marketed.

With regard to Pyrimal, the production was stated never to have been more than 500 kilos per month, owing to shortage of equipment. The Schering process for Pyrimal starts with acrolein purchased from Wacker, which is converted by the usual steps to B-ethoxyacrolein acetal; this is condensed with guanidine sulfate in the presence of concentrated HCl, at 400°C, to give an 80% (last stage) yield of 2-aminopyrimidine.

Dr. Schoeller stated that the Deutsche Hydrier Werke had been very active in filing patent applications for aminoheterocyclic compounds.

When x becomes 3 or higher, the synthetic difficulties are very great. The best compounds are those in which R equals H, and x is 1 or 2. In other cases markedly lessened activity results. It was stated that marfanil has some activity against aerobic bacteria but is specific against anaerobic bacteria. In vitro this seems to be true, but it is doubtful that it is true in vivo.

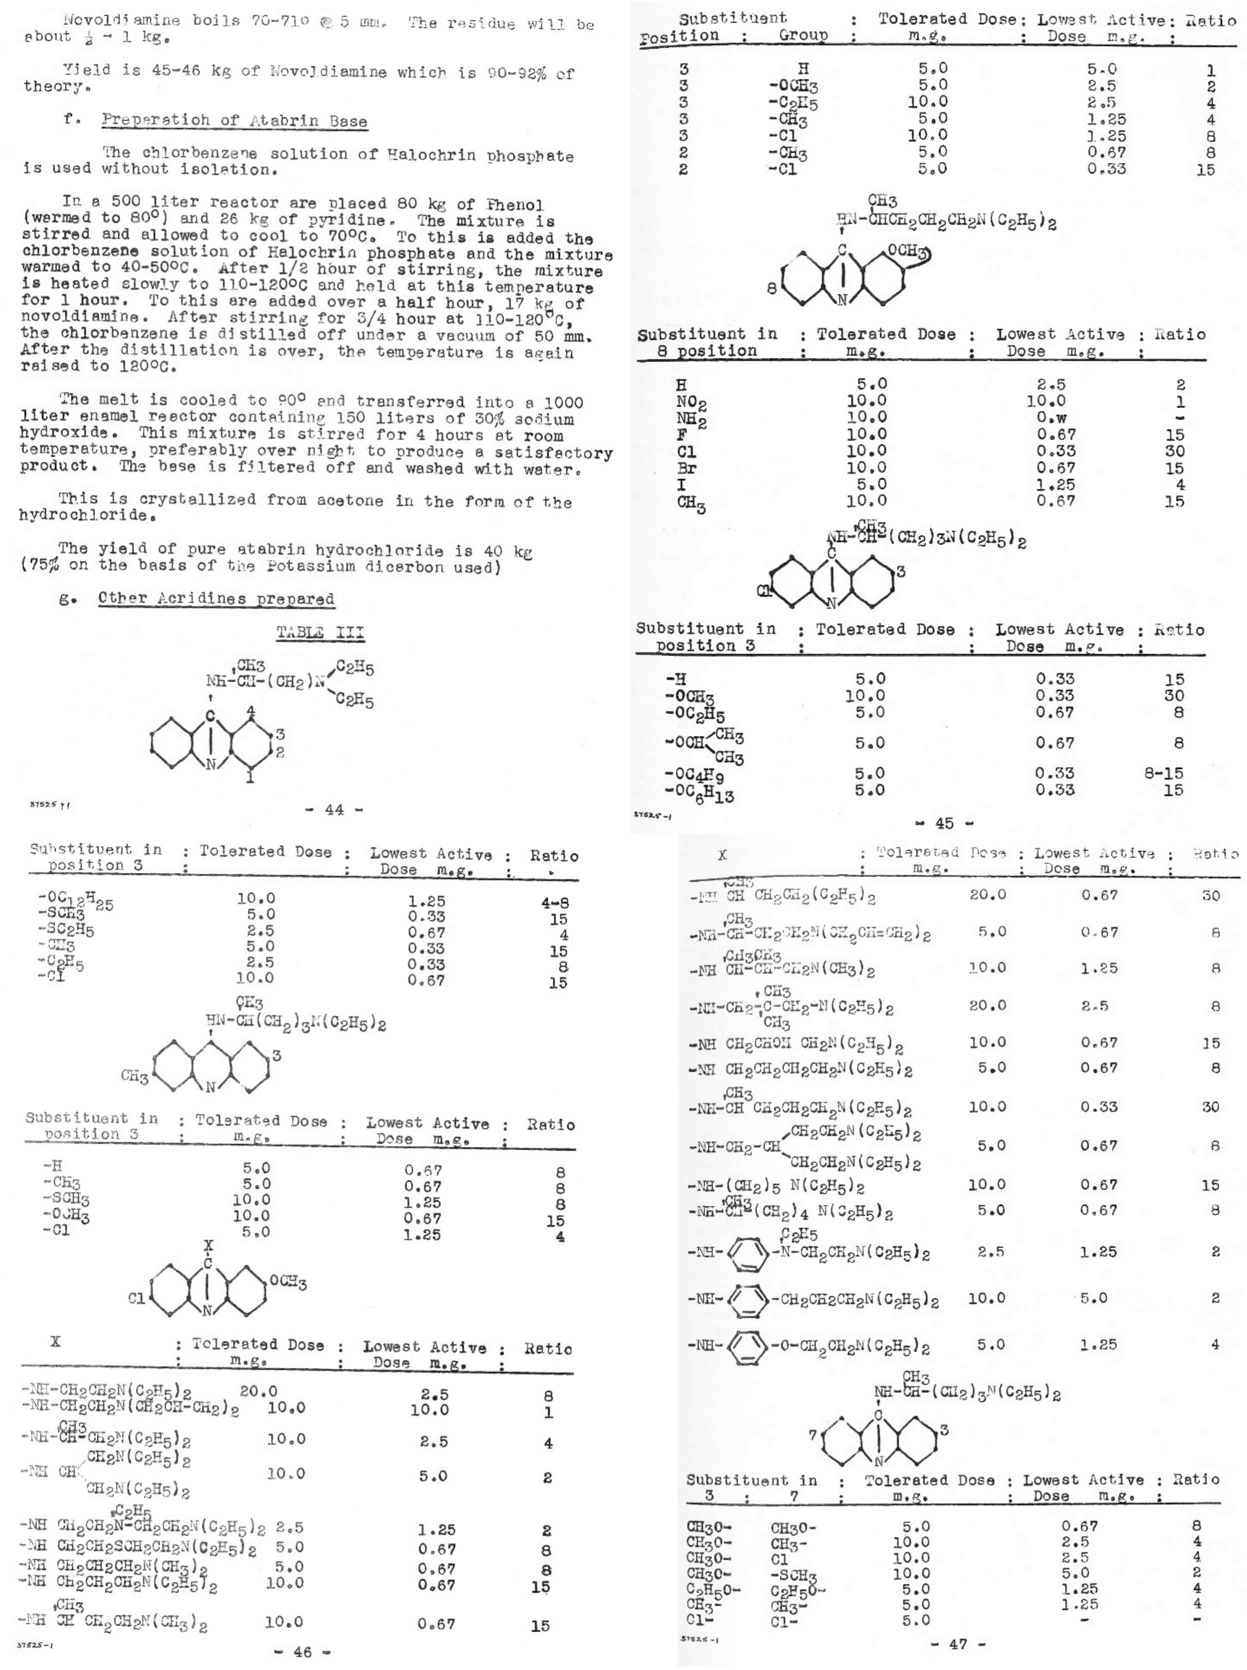
4. Certuna (Oprochin, Cilional)

a. Preparation of Dimethylaminobutanol

$CH_3CHOHCH_2CH_2N(CH_3)_2$

230 g. dimethylaminoisobutanone are dissolved in 800 c.c. of water and 120 cc. of glacial acetic acid. The solution is cooled externally to 15-25°C and to it are added over a 5-hour period 2.6 liters of dilute acetic acid (made from 1.5 liters of glacial acetic acid diluted to 2.7 liters and 5.2 kg. of 4% sodium amalgam.

Figure A.77: Structure-activity relationship (SAR) optimization of antimalarial molecules [CIOS XXV-54].



Novoldiamine boils 70-71o @ 5 mm. The residue will be about ½ - 1 kg.

Yield is 45-46 kg of Novoldiamine which is 90-92% of theory.

f. Preparation of Atabrin Base

The chlorbenzene solution of Halochrin phosphate is used without isolation.

In a 500 liter reactor are placed 80 kg of Phenol (warmed to 80°) and 26 kg of pyridine. The mixture is stirred and allowed to cool to 70°C. To this is added the chlorbenzene solution of Halochrin phosphate and the mixture warmed to 40-50°C. After 1/2 hour of stirring, the mixture is heated slowly to 110-120°C and held at this temperature for 1 hour. To this are added over a half hour, 17 kg of novoldiamine. After stirring for 3/4 hour at 110-120°C, the chlorbenzene is distilled off under a vacuum of 50 mm. After the distillation is over, the temperature is again raised to 120°C.

The melt is cooled to 90° and transferred into a 1000 liter enamel reactor containing 150 liters of 30% sodium hydroxide. This mixture is stirred for 4 hours at room temperature, preferably over night to produce a satisfactory product. The base is filtered off and washed with water.

This is crystallized from acetone in the form of the hydrochloride.

The yield of pure atabrin hydrochloride is 40 kg (75% on the basis of the Potassium dicarbon used)

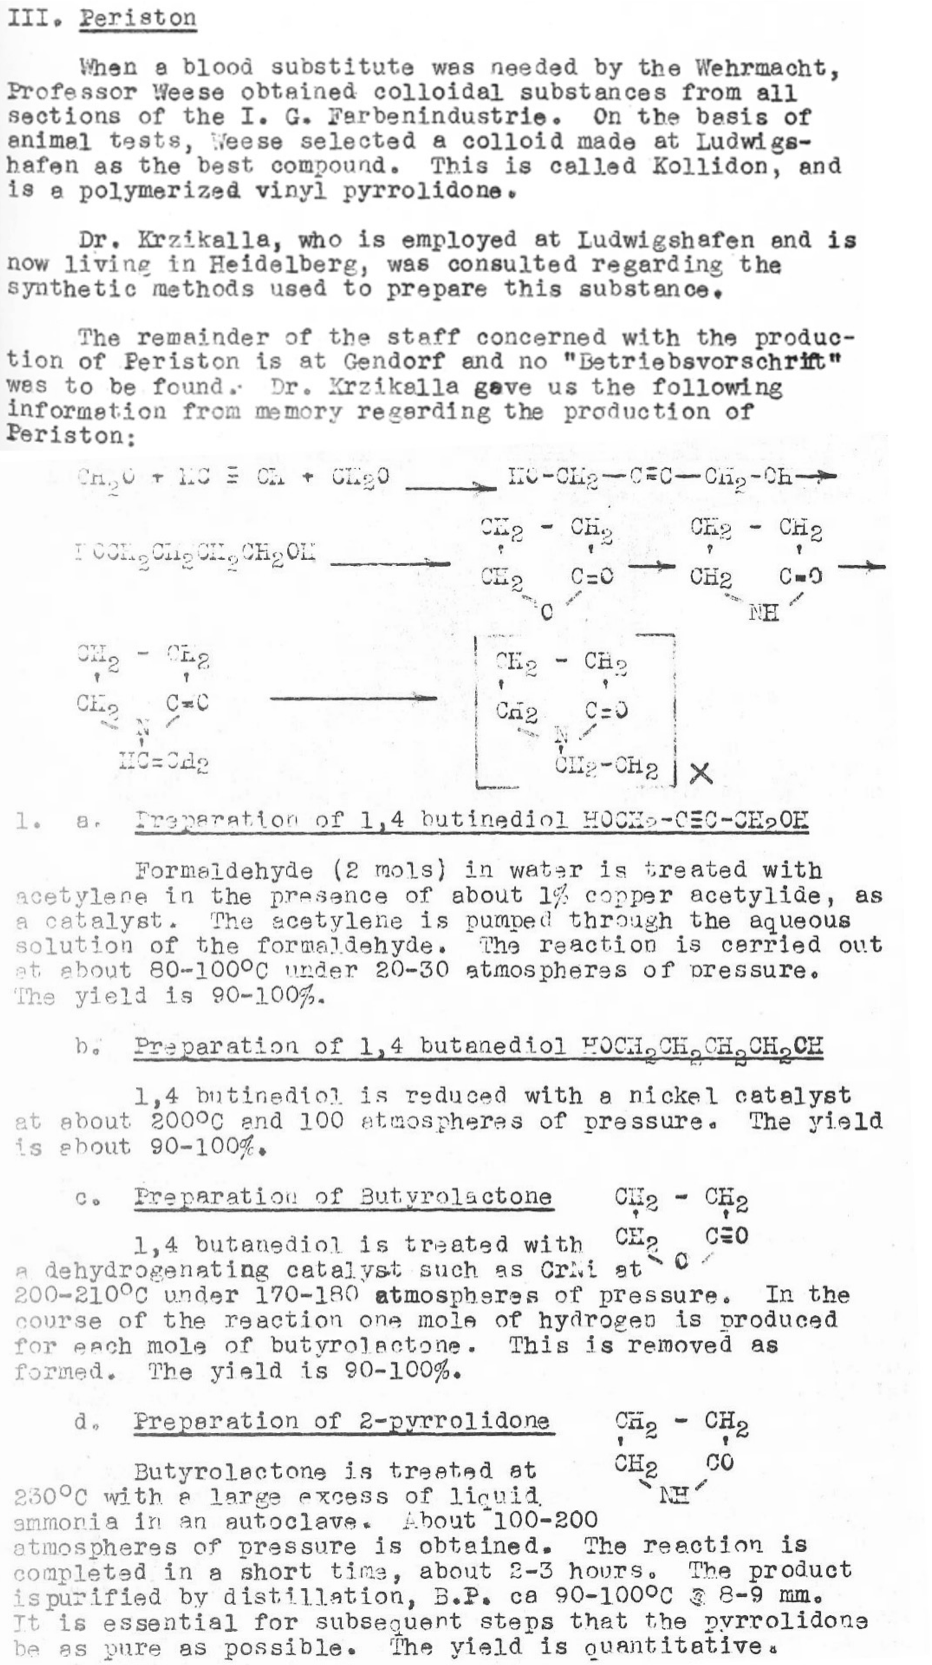
Figure A.78: Structure-activity relationship (SAR) optimization of antimalarial molecules [CIOS XXV-54].



III. Periston

When a blood substitute was needed by the Wehrmacht, Professor Weese obtained colloidal substances from all sections of the I. G. Farbenindustrie. On the basis of animal tests, Weese selected a colloid made at Ludwigshafen as the best compound. This is called Kollidon, and is a polymerized vinyl pyrrolidone.

Dr. Krzikalla, who is employed at Ludwigshafen and is now living in Heidelberg, was consulted regarding the synthetic methods used to prepare this substance.

The remainder of the staff concerned with the production of Periston is at Gendorf and no "Betriebsvorschrift" was to be found. Dr. Krzikalla gave us the following information from memory regarding the production of Periston:

$CH_2O + HC \equiv CH + CH_2O \longrightarrow HO-CH_2-C\equiv C-CH_2-OH \rightarrow$

$HOCH_2CH_2CH_2CH_2OH \longrightarrow$

1. a. Preparation of 1,4 butinediol $HOCH_2-C\equiv C-CH_2OH$

Formaldehyde (2 mols) in water is treated with acetylene in the presence of about 1% copper acetylide, as a catalyst. The acetylene is pumped through the aqueous solution of the formaldehyde. The reaction is carried out at about 80-100°C under 20-30 atmospheres of pressure. The yield is 90-100%.

b. Preparation of 1,4 butanediol $HOCH_2CH_2CH_2CH_2OH$

1,4 butinediol is reduced with a nickel catalyst at about 200°C and 100 atmospheres of pressure. The yield is about 90-100%.

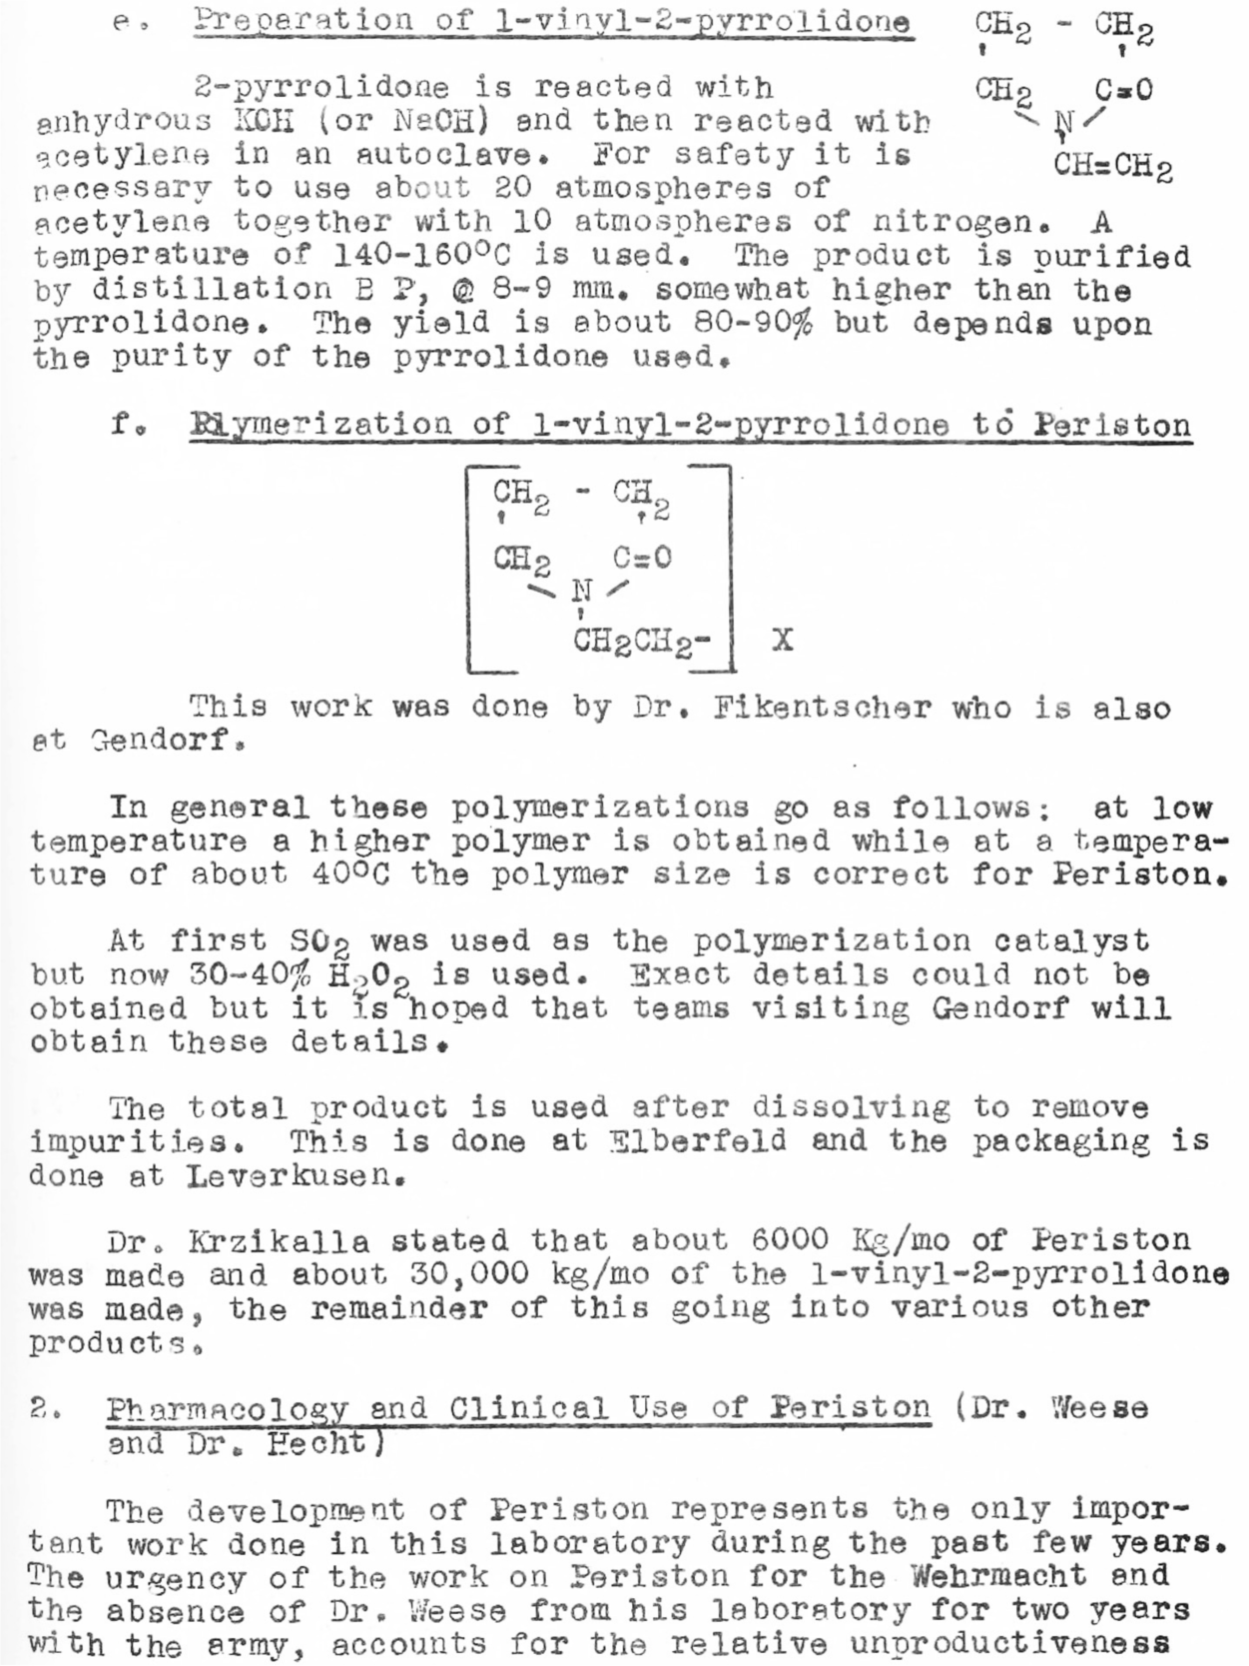
c. Preparation of Butyrolactone

1,4 butanediol is treated with a dehydrogenating catalyst such as CrNi at 200-210°C under 170-180 atmospheres of pressure. In the course of the reaction one mole of hydrogen is produced for each mole of butyrolactone. This is removed as formed. The yield is 90-100%.

d. Preparation of 2-pyrrolidone

Butyrolactone is treated at 230°C with a large excess of liquid ammonia in an autoclave. About 100-200 atmospheres of pressure is obtained. The reaction is completed in a short time, about 2-3 hours. The product is purified by distillation, B.P. ca 90-100°C @ 8-9 mm. It is essential for subsequent steps that the pyrrolidone be as pure as possible. The yield is quantitative.

Figure A.79: Information on periston [CIOS XXV-54].



e. Preparation of 1-vinyl-2-pyrrolidone

CH2 - CH2
CH2 C=O
N
CH=CH2

2-pyrrolidone is reacted with anhydrous KOH (or NaOH) and then reacted with acetylene in an autoclave. For safety it is necessary to use about 20 atmospheres of acetylene together with 10 atmospheres of nitrogen. A temperature of 140-160°C is used. The product is purified by distillation B P, @ 8-9 mm. somewhat higher than the pyrrolidone. The yield is about 80-90% but depends upon the purity of the pyrrolidone used.

f. Polymerization of 1-vinyl-2-pyrrolidone to Periston

This work was done by Dr. Fikentscher who is also at Gendorf.

In general these polymerizations go as follows: at low temperature a higher polymer is obtained while at a temperature of about 40°C the polymer size is correct for Periston.

At first SO_2 was used as the polymerization catalyst but now 30-40% H_2O_2 is used. Exact details could not be obtained but it is hoped that teams visiting Gendorf will obtain these details.

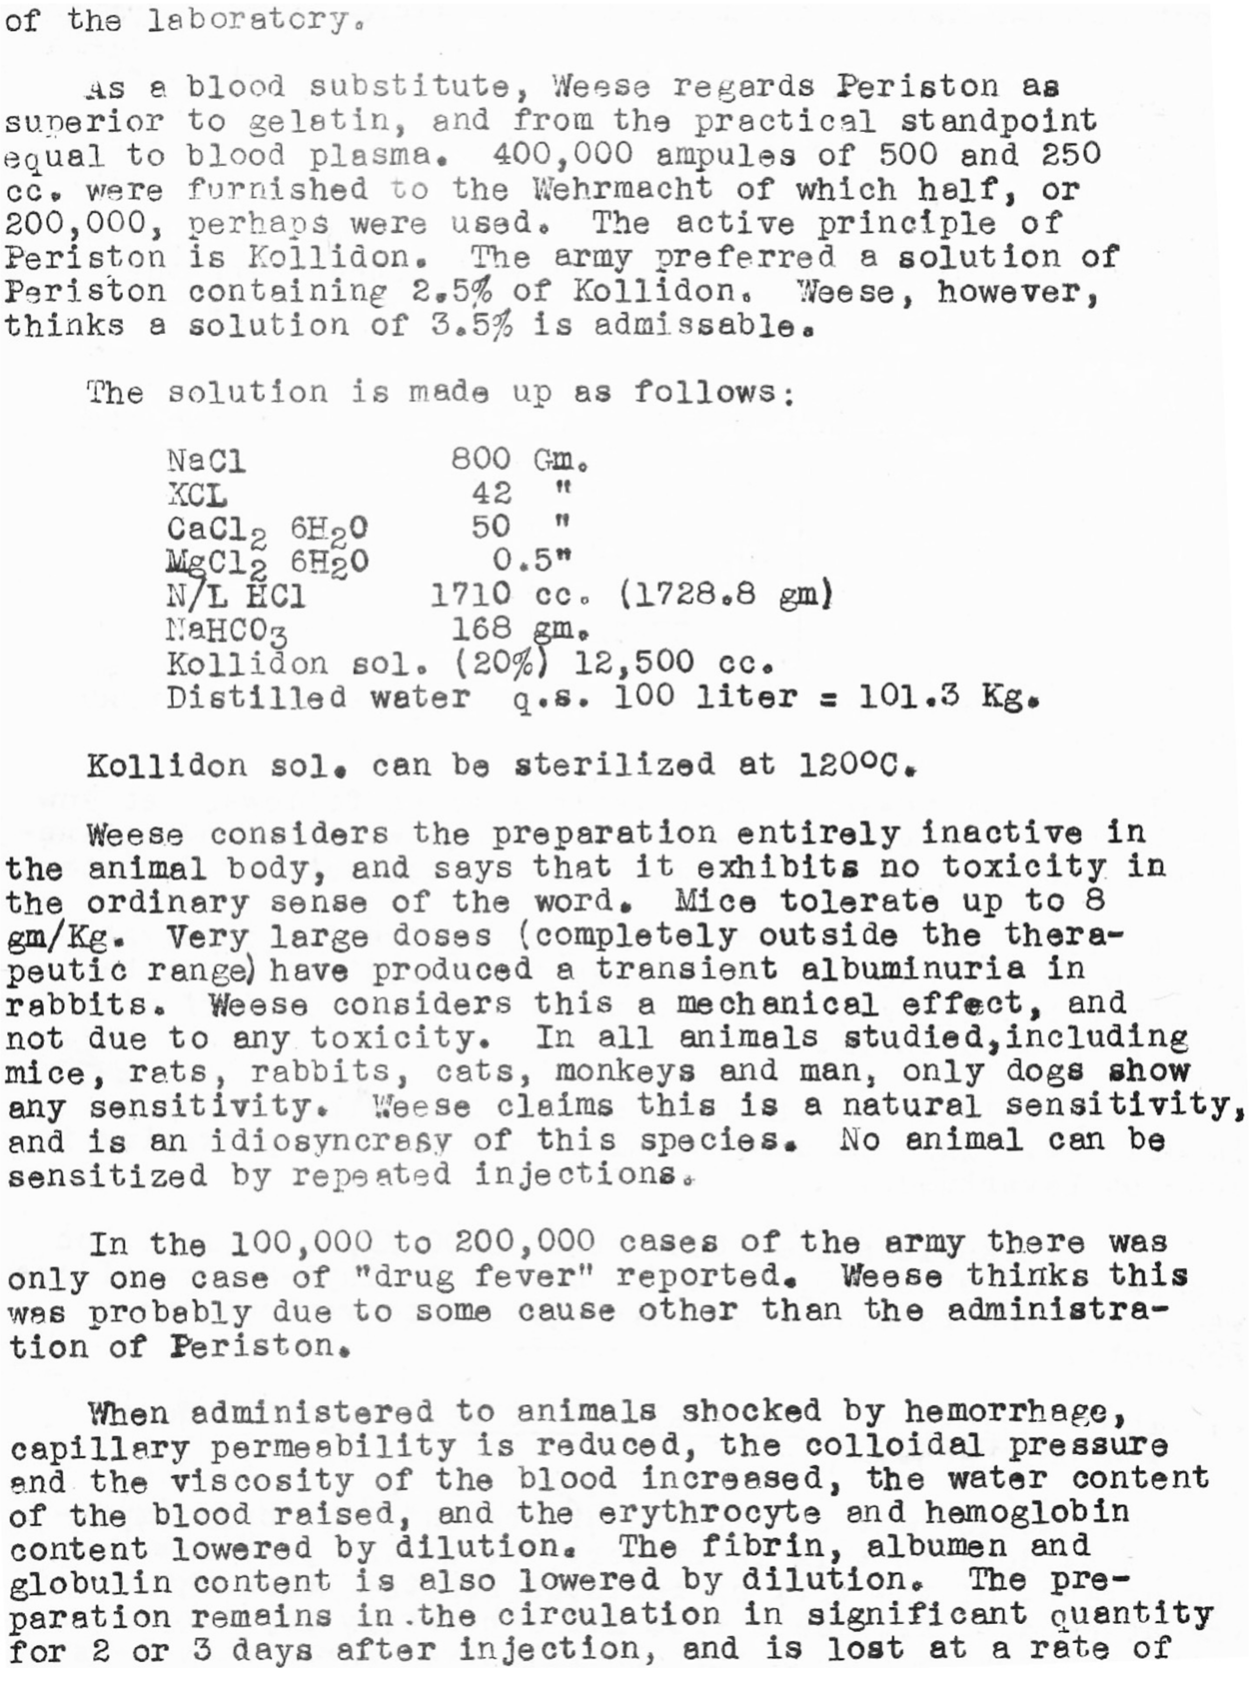
The total product is used after dissolving to remove impurities. This is done at Elberfeld and the packaging is done at Leverkusen.

Dr. Krzikalla stated that about 6000 Kg/mo of Periston was made and about 30,000 kg/mo of the 1-vinyl-2-pyrrolidone was made, the remainder of this going into various other products.

2. Pharmacology and Clinical Use of Periston (Dr. Weese and Dr. Hecht)

The development of Periston represents the only important work done in this laboratory during the past few years. The urgency of the work on Periston for the Wehrmacht and the absence of Dr. Weese from his laboratory for two years with the army, accounts for the relative unproductiveness

Figure A.80: Information on periston [CIOS XXV-54].



of the laboratory.

As a blood substitute, Weese regards Periston as superior to gelatin, and from the practical standpoint equal to blood plasma. 400,000 ampules of 500 and 250 cc. were furnished to the Wehrmacht of which half, or 200,000, perhaps were used. The active principle of Periston is Kollidon. The army preferred a solution of Periston containing 2.5% of Kollidon. Weese, however, thinks a solution of 3.5% is admissable.

The solution is made up as follows:

NaCl	800 Gm.
XCL	42 "
$CaCl_2$ $6H_2O$	50 "
$MgCl_2$ $6H_2O$	0.5"
N/L HCl	1710 cc. (1728.8 gm)
$NaHCO_3$	168 gm.
Kollidon sol. (20%)	12,500 cc.
Distilled water	q.s. 100 liter = 101.3 Kg.

Kollidon sol. can be sterilized at 120°C.

Weese considers the preparation entirely inactive in the animal body, and says that it exhibits no toxicity in the ordinary sense of the word. Mice tolerate up to 8 gm/Kg. Very large doses (completely outside the therapeutic range) have produced a transient albuminuria in rabbits. Weese considers this a mechanical effect, and not due to any toxicity. In all animals studied, including mice, rats, rabbits, cats, monkeys and man, only dogs show any sensitivity. Weese claims this is a natural sensitivity, and is an idiosyncrasy of this species. No animal can be sensitized by repeated injections.

In the 100,000 to 200,000 cases of the army there was only one case of "drug fever" reported. Weese thinks this was probably due to some cause other than the administration of Periston.

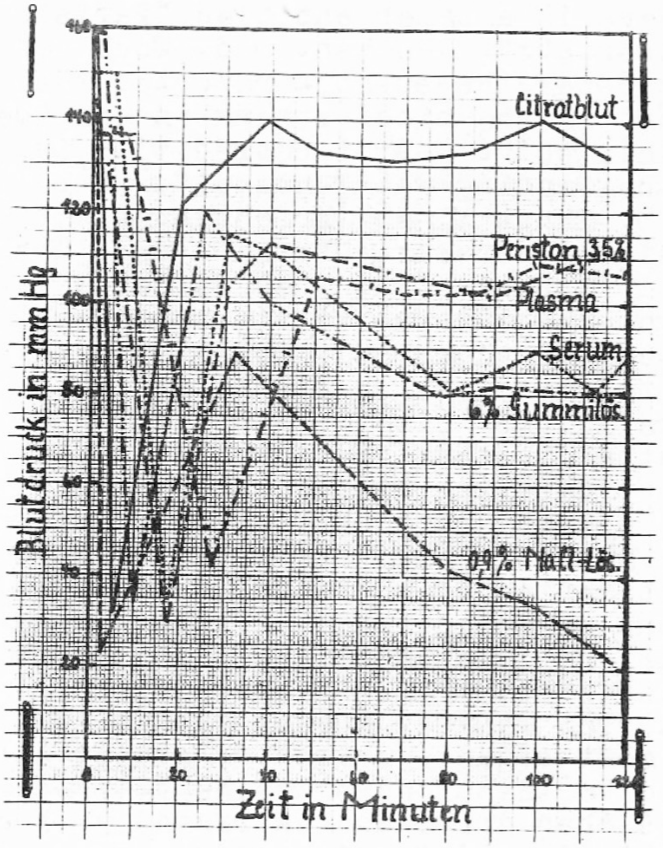
When administered to animals shocked by hemorrhage, capillary permeability is reduced, the colloidal pressure and the viscosity of the blood increased, the water content of the blood raised, and the erythrocyte and hemoglobin content lowered by dilution. The fibrin, albumen and globulin content is also lowered by dilution. The preparation remains in the circulation in significant quantity for 2 or 3 days after injection, and is lost at a rate of

Figure A.81: Information on periston [CIOS XXV-54].

about 50% per day. The preparation is excreted by the kidney for two or three days, but thereafter cannot be found again in the urine. Not more than 50% can be accounted for by urinary excretion. Hecht believes that only the smaller molecules, possibly up to mol. wt. 10,000 are excreted, the rest being changed in some unknown manner in the body. The doses recommended are up to 500 cc. for adults and 25 cc/kg. body weight for infants.

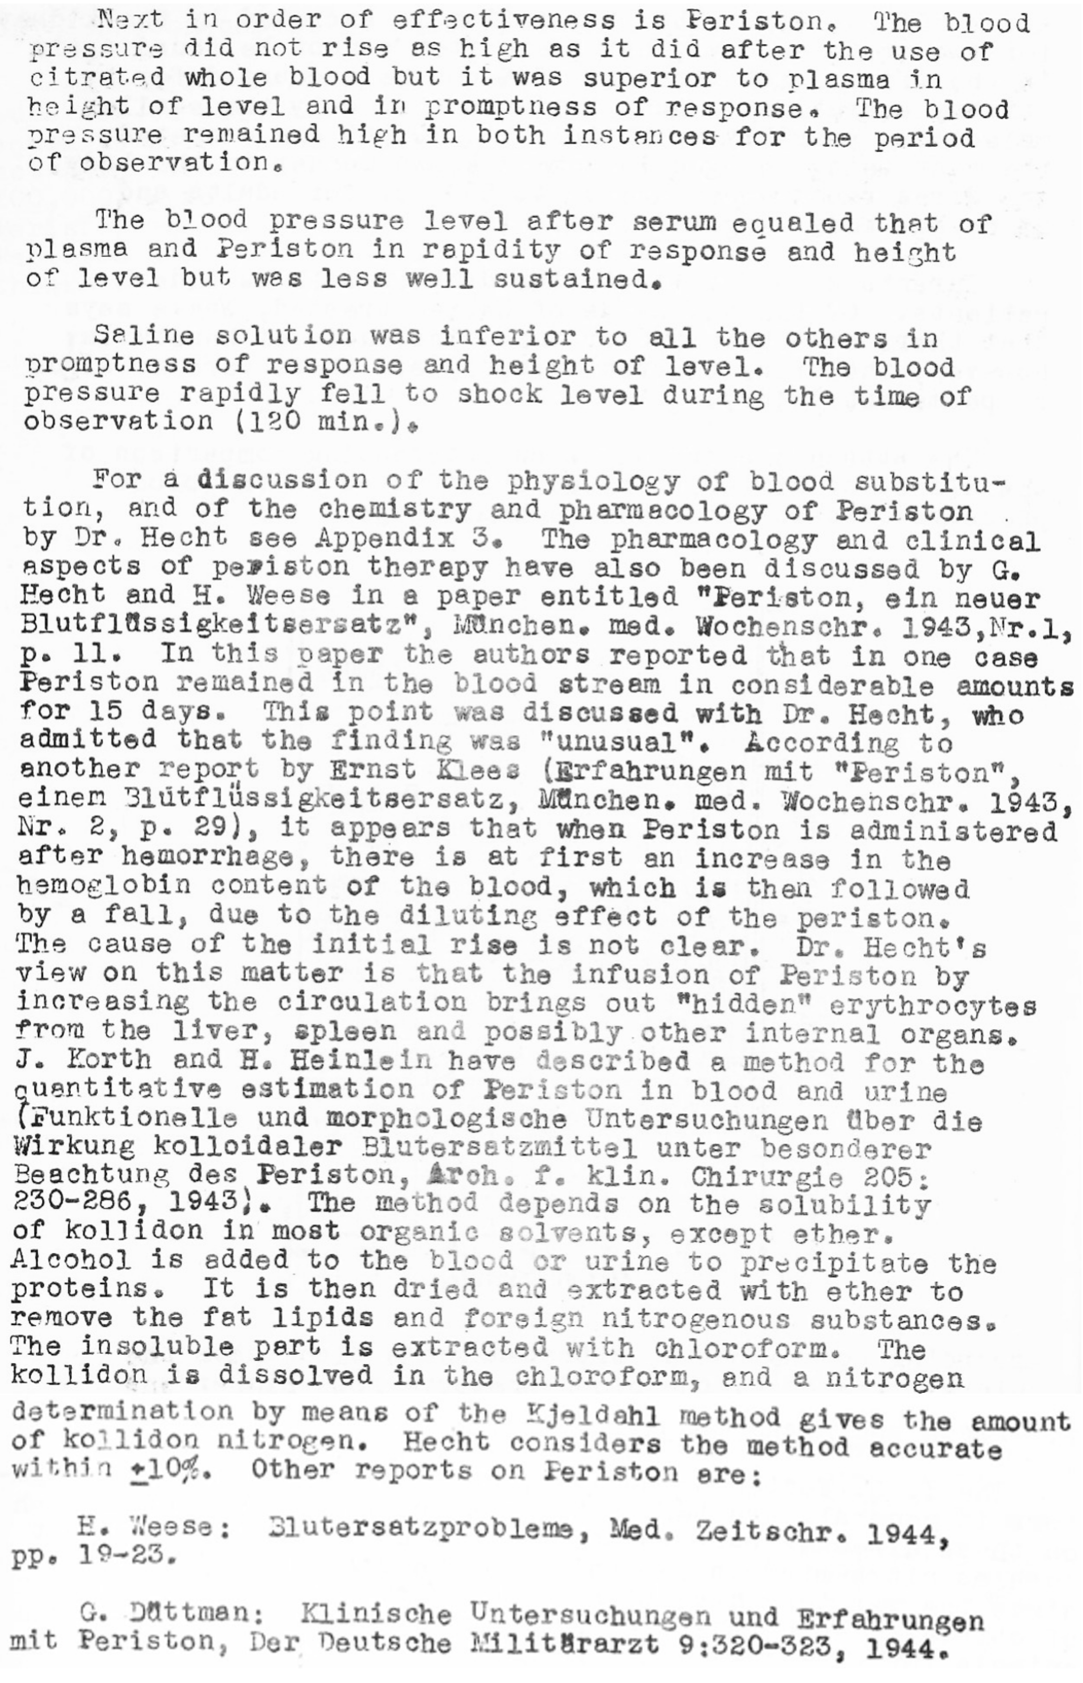
Infants do not tolerate the drug as well as older patients. Of the thousands of babies treated, Weese says that there have been two or three instances of hematuria; however, the urine cleared promptly and there were no signs of permanent injury.

The attached chart shows an interesting comparison of the effect of different blood substitutes on the blood pressure of cats after severe hemorrhage.



According to the chart, citrated whole blood gave the quickest response; the blood pressure rose higher and remained high for the duration of observation.

Figure A.82: Information on periston [CIOS XXV-54].



Next in order of effectiveness is Periston. The blood pressure did not rise as high as it did after the use of citrated whole blood but it was superior to plasma in height of level and in promptness of response. The blood pressure remained high in both instances for the period of observation.

The blood pressure level after serum equaled that of plasma and Periston in rapidity of response and height of level but was less well sustained.

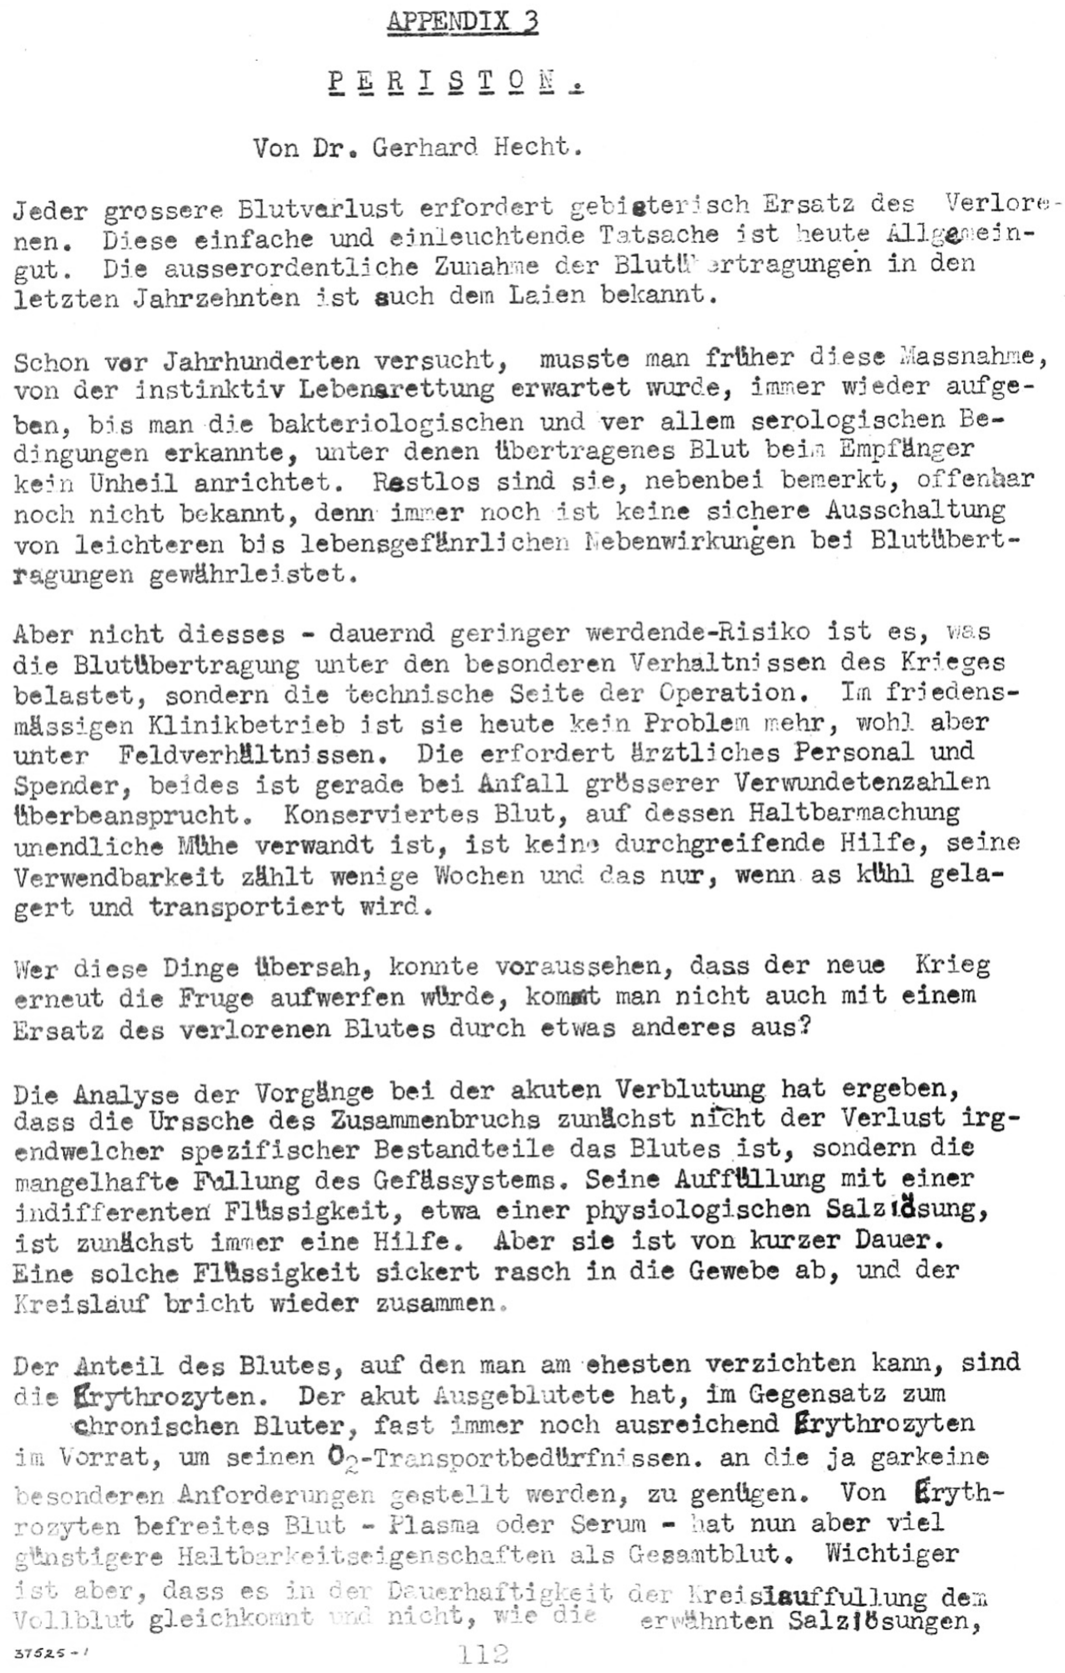
Saline solution was inferior to all the others in promptness of response and height of level. The blood pressure rapidly fell to shock level during the time of observation (120 min.).

For a discussion of the physiology of blood substitution, and of the chemistry and pharmacology of Periston by Dr. Hecht see Appendix 3. The pharmacology and clinical aspects of periston therapy have also been discussed by G. Hecht and H. Weese in a paper entitled "Periston, ein neuer Blutflüssigkeitsersatz", München. med. Wochenschr. 1943, Nr. 1, p. 11. In this paper the authors reported that in one case Periston remained in the blood stream in considerable amounts for 15 days. This point was discussed with Dr. Hecht, who admitted that the finding was "unusual". According to another report by Ernst Klees (Erfahrungen mit "Periston", einem Blütflüssigkeitsersatz, München. med. Wochenschr. 1943, Nr. 2, p. 29), it appears that when Periston is administered after hemorrhage, there is at first an increase in the hemoglobin content of the blood, which is then followed by a fall, due to the diluting effect of the periston. The cause of the initial rise is not clear. Dr. Hecht's view on this matter is that the infusion of Periston by increasing the circulation brings out "hidden" erythrocytes from the liver, spleen and possibly other internal organs. J. Korth and H. Heinlein have described a method for the quantitative estimation of Periston in blood and urine (Funktionelle und morphologische Untersuchungen über die Wirkung kolloidaler Blutersatzmittel unter besonderer Beachtung des Periston, Arch. f. klin. Chirurgie 205: 230-286, 1943). The method depends on the solubility of kollidon in most organic solvents, except ether. Alcohol is added to the blood or urine to precipitate the proteins. It is then dried and extracted with ether to remove the fat lipids and foreign nitrogenous substances. The insoluble part is extracted with chloroform. The kollidon is dissolved in the chloroform, and a nitrogen determination by means of the Kjeldahl method gives the amount of kollidon nitrogen. Hecht considers the method accurate within ±10%. Other reports on Periston are:

H. Weese: Blutersatzprobleme, Med. Zeitschr. 1944, pp. 19-23.

G. Düttman: Klinische Untersuchungen und Erfahrungen mit Periston, Der Deutsche Militärarzt 9:320-323, 1944.

Figure A.83: Information on periston [CIOS XXV-54].



APPENDIX 3

PERISTON.

Von Dr. Gerhard Hecht.

Jeder grossere Blutverlust erfordert gebieterisch Ersatz des Verlorenen. Diese einfache und einleuchtende Tatsache ist heute Allgemeingut. Die ausserordentliche Zunahme der Blutübertragungen in den letzten Jahrzehnten ist auch dem Laien bekannt.

Schon vor Jahrhunderten versucht, musste man früher diese Massnahme, von der instinktiv Lebensrettung erwartet wurde, immer wieder aufgeben, bis man die bakteriologischen und ver allem serologischen Bedingungen erkannte, unter denen übertragenes Blut beim Empfänger kein Unheil anrichtet. Restlos sind sie, nebenbei bemerkt, offenbar noch nicht bekannt, denn immer noch ist keine sichere Ausschaltung von leichteren bis lebensgefährlichen Nebenwirkungen bei Blutübertragungen gewährleistet.

Aber nicht diesses - dauernd geringer werdende-Risiko ist es, was die Blutübertragung unter den besonderen Verhaltnissen des Krieges belastet, sondern die technische Seite der Operation. Im friedensmässigen Klinikbetrieb ist sie heute kein Problem mehr, wohl aber unter Feldverhältnissen. Die erfordert ärztliches Personal und Spender, beides ist gerade bei Anfall grösserer Verwundetenzahlen überbeansprucht. Konserviertes Blut, auf dessen Haltbarmachung unendliche Mühe verwandt ist, ist keine durchgreifende Hilfe, seine Verwendbarkeit zählt wenige Wochen und das nur, wenn as kühl gelagert und transportiert wird.

Wer diese Dinge übersah, konnte voraussehen, dass der neue Krieg erneut die Fruge aufwerfen würde, kommt man nicht auch mit einem Ersatz des verlorenen Blutes durch etwas anderes aus?

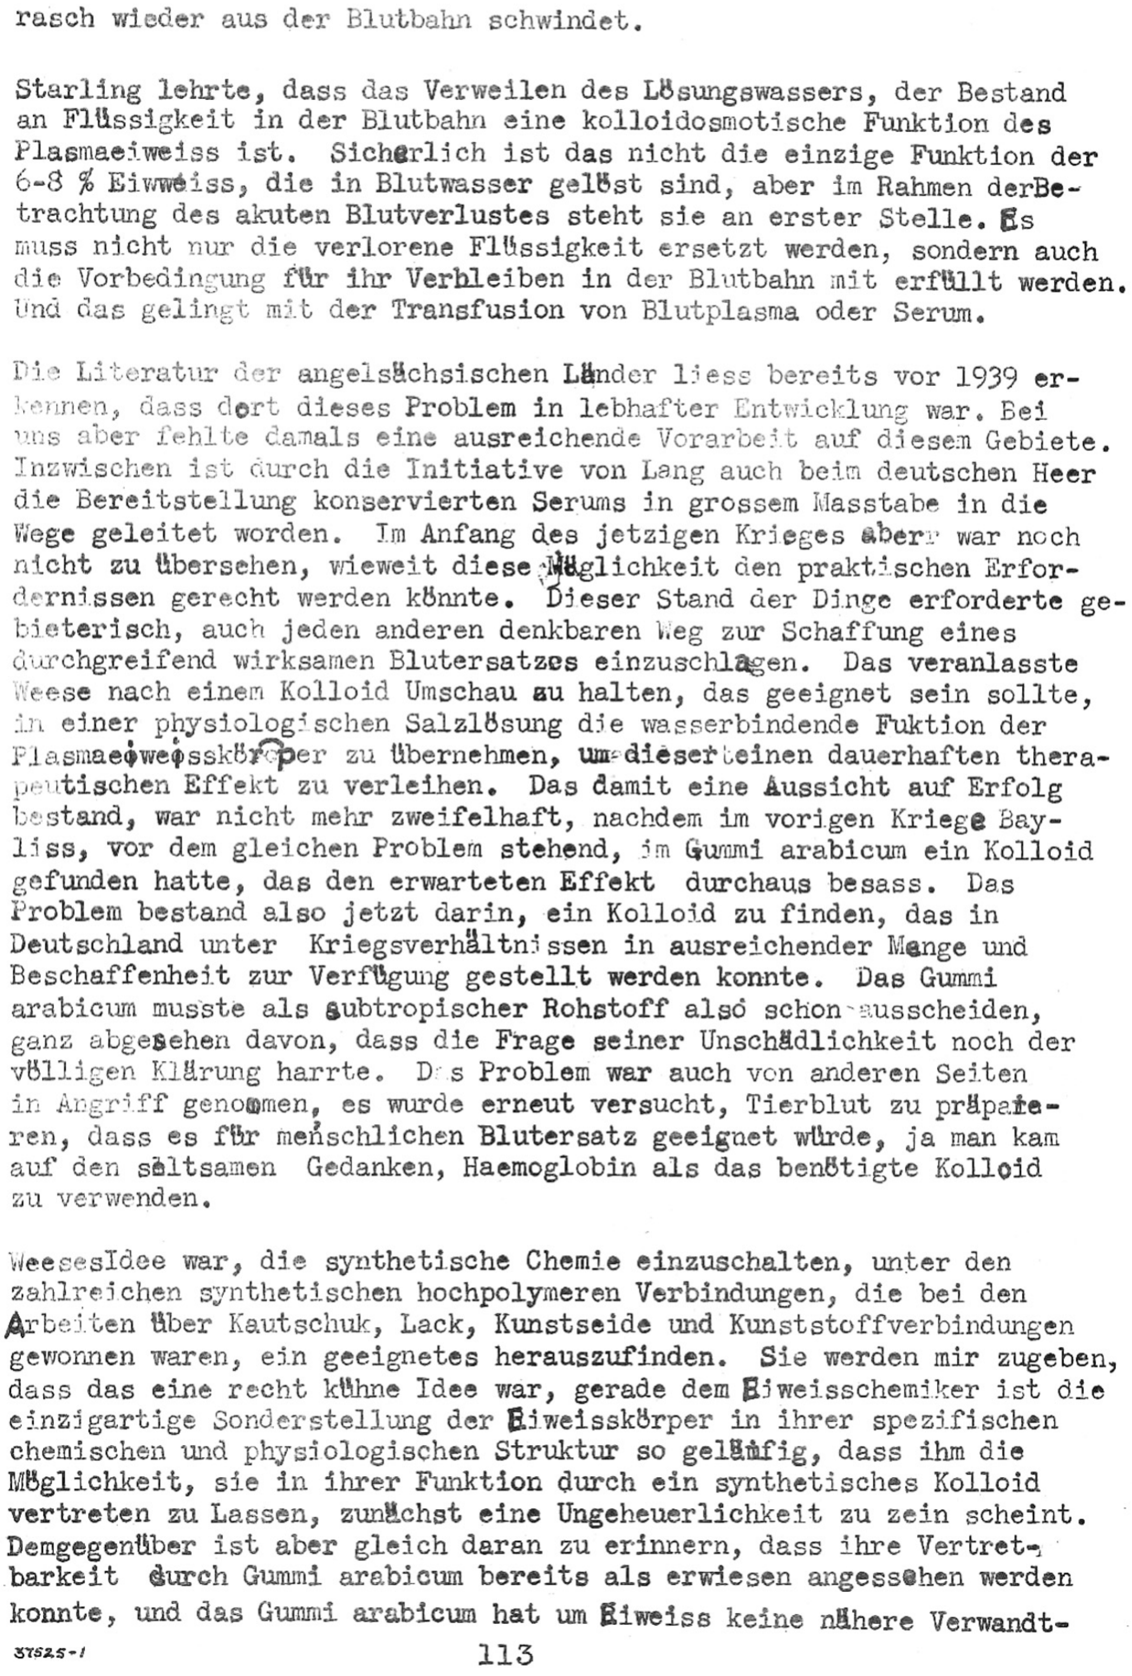
Die Analyse der Vorgänge bei der akuten Verblutung hat ergeben, dass die Urssche des Zusammenbruchs zunächst nicht der Verlust irgendwelcher spezifischer Bestandteile das Blutes ist, sondern die mangelhafte Füllung des Gefässystems. Seine Auffüllung mit einer indifferenten Flüssigkeit, etwa einer physiologischen Salzlösung, ist zunächst immer eine Hilfe. Aber sie ist von kurzer Dauer. Eine solche Flüssigkeit sickert rasch in die Gewebe ab, und der Kreislauf bricht wieder zusammen.

Der Anteil des Blutes, auf den man am ehesten verzichten kann, sind die Erythrozyten. Der akut Ausgeblutete hat, im Gegensatz zum chronischen Bluter, fast immer noch ausreichend Erythrozyten im Vorrat, um seinen O_2-Transportbedürfnissen. an die ja garkeine besonderen Anforderungen gestellt werden, zu genügen. Von Erythrozyten befreites Blut - Plasma oder Serum - hat nun aber viel günstigere Haltbarkeitseigenschaften als Gesamtblut. Wichtiger ist aber, dass es in der Dauerhaftigkeit der Kreislauffullung dem Vollblut gleichkomnt und nicht, wie die erwähnten Salzlösungen,

37525-1

112

Figure A.84: Information on periston [CIOS XXV-54].



rasch wieder aus der Blutbahn schwindet.

Starling lehrte, dass das Verweilen des Lösungswassers, der Bestand an Flüssigkeit in der Blutbahn eine kolloidosmotische Funktion des Plasmaeiweiss ist. Sicherlich ist das nicht die einzige Funktion der 6-8 % Eiwweiss, die in Blutwasser gelöst sind, aber im Rahmen derBetrachtung des akuten Blutverlustes steht sie an erster Stelle. Es muss nicht nur die verlorene Flüssigkeit ersetzt werden, sondern auch die Vorbedingung für ihr Verbleiben in der Blutbahn mit erfüllt werden. Und das gelingt mit der Transfusion von Blutplasma oder Serum.

Die Literatur der angelsächsischen Länder liess bereits vor 1939 erkennen, dass dort dieses Problem in lebhafter Entwicklung war. Bei uns aber fehlte damals eine ausreichende Vorarbeit auf diesem Gebiete. Inzwischen ist durch die Initiative von Lang auch beim deutschen Heer die Bereitstellung konservierten Serums in grossem Masstabe in die Wege geleitet worden. Im Anfang des jetzigen Krieges aber war noch nicht zu übersehen, wieweit diese Möglichkeit den praktischen Erfordernissen gerecht werden könnte. Dieser Stand der Dinge erforderte gebieterisch, auch jeden anderen denkbaren Weg zur Schaffung eines durchgreifend wirksamen Blutersatzes einzuschlagen. Das veranlasste Weese nach einem Kolloid Umschau zu halten, das geeignet sein sollte, in einer physiologischen Salzlösung die wasserbindende Fuktion der Plasmaeiweisskörper zu übernehmen, um dieser einen dauerhaften therapeutischen Effekt zu verleihen. Das damit eine Aussicht auf Erfolg bestand, war nicht mehr zweifelhaft, nachdem im vorigen Kriege Bayliss, vor dem gleichen Problem stehend, im Gummi arabicum ein Kolloid gefunden hatte, das den erwarteten Effekt durchaus besass. Das Problem bestand also jetzt darin, ein Kolloid zu finden, das in Deutschland unter Kriegsverhältnissen in ausreichender Menge und Beschaffenheit zur Verfügung gestellt werden konnte. Das Gummi arabicum musste als subtropischer Rohstoff also schon ausscheiden, ganz abgesehen davon, dass die Frage seiner Unschädlichkeit noch der völligen Klärung harrte. Das Problem war auch von anderen Seiten in Angriff genommen, es wurde erneut versucht, Tierblut zu präparieren, dass es für menschlichen Blutersatz geeignet würde, ja man kam auf den seltsamen Gedanken, Haemoglobin als das benötigte Kolloid zu verwenden.

WeesesIdee war, die synthetische Chemie einzuschalten, unter den zahlreichen synthetischen hochpolymeren Verbindungen, die bei den Arbeiten über Kautschuk, Lack, Kunstseide und Kunststoffverbindungen gewonnen waren, ein geeignetes herauszufinden. Sie werden mir zugeben, dass das eine recht kühne Idee war, gerade dem Eiweisschemiker ist die einzigartige Sonderstellung der Eiweisskörper in ihrer spezifischen chemischen und physiologischen Struktur so geläufig, dass ihm die Möglichkeit, sie in ihrer Funktion durch ein synthetisches Kolloid vertreten zu Lassen, zunächst eine Ungeheuerlichkeit zu zein scheint. Demgegenüber ist aber gleich daran zu erinnern, dass ihre Vertretbarkeit durch Gummi arabicum bereits als erwiesen angessehen werden konnte, und das Gummi arabicum hat um Eiweiss keine nähere Verwandt-

37525-1 113

Figure A.85: Information on periston [CIOS XXV-54].

schaft, als ein synthetischer Körper, ich werde noch zeigen, dass das Umgekehrte gilt.

Ich möchte nun übergehen, welche Verbindungen wir damals alle auf ihre Eignung geprüft haben und nur kurz andeuten, wie die Prüfung der zur Auswahl gestandenen Körper durchgeführt wurde. Natürlich mussten sie wasserlöslich sein. Da es im allgemeinen nicht das Ziel der auf einschlägigen Gebieten tätigen Synthetiker war, wasserlösliche Verbindungen zu gewinnen, war die Auswahl unter den bereits hergestellten Verbindungen nicht übermässwig gross, und engte sich noch weiter ein, als sie auf ihre Wechselwirkungen mit den in physiologischen Lösungen notwendig enthaltenen Salzen geprüft wurden: viele von ihnen bildeten u.B. unlösliche Kalksalze. Dann kam die wichtigste Forderung in Sinne des primus non nocere: ihre anstandslos Verträglichkeit bei intravenöser Injektion grösster Dosen. Dann erst kam die kolloidchemische Seite: Der kolloidosmotische Druck musste grössenordnungsmässig zu dem des Plassweiweissen passen und schliesslich der Tierversuch mit einem grösseren Blutverlust des Leben retten, als es die kolloidfreie Salzlösung es tut.

In dieser Weise kamen wir zur Auswahl eines bestimaten Kolloides, des "Kollidons", das in geeigneter Salzlösung gelöst unter der Bezeichnung "Periston" dann klinisch geprüft und seit 3 Jahren in nunmehr hunderttausenden von Fällen beim Heer praktisch benutzt worden ist. Über den klinischen Erfolg nur einige ganz kurze Angaben: Zunächst ist die Verträglichkeit über allem Zweifel erhaben, ausser ganz vereinzeltn Fallen von Fieberreaktion - unendliche viel seltener als nach Blut- oder Serumtransfusionen - sind uns keine für das Präparat spezifischen Nebenwirkungen gemeldet worden. Und über den Effekt liegen neben kühlen und reservierten, in der Mehrzahl absolut positive Berichte von kriegschirurgischer Seite vor. Daneben wird in heimischen Kliniken, selbst dort also, wo die Bluttransfusion mölich wäre, viel Periston benutzt, sicherlich wäre es noch viel mehr, wenn die Produktion nicht von der Seite der Glasampullen her hinter den Anforderungen zurückbliebe.

An dieser Stelle möchte ich es als meine Auggabe-ansehen, Sie mit einigen Eigenachaften dieses Kolloides bekannt zu machen. Es ist in dem von Herrn Dr. Reppe geleiteten I.G. Laboratorium in Ludwigshafen erfunden worden. Nach einer von Reppe entwickelten Synthese wird N-Vinylpyrrolidon

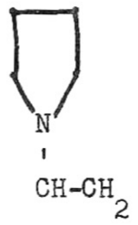


Figure A.86: Information on periston [CIOS XXV-54].

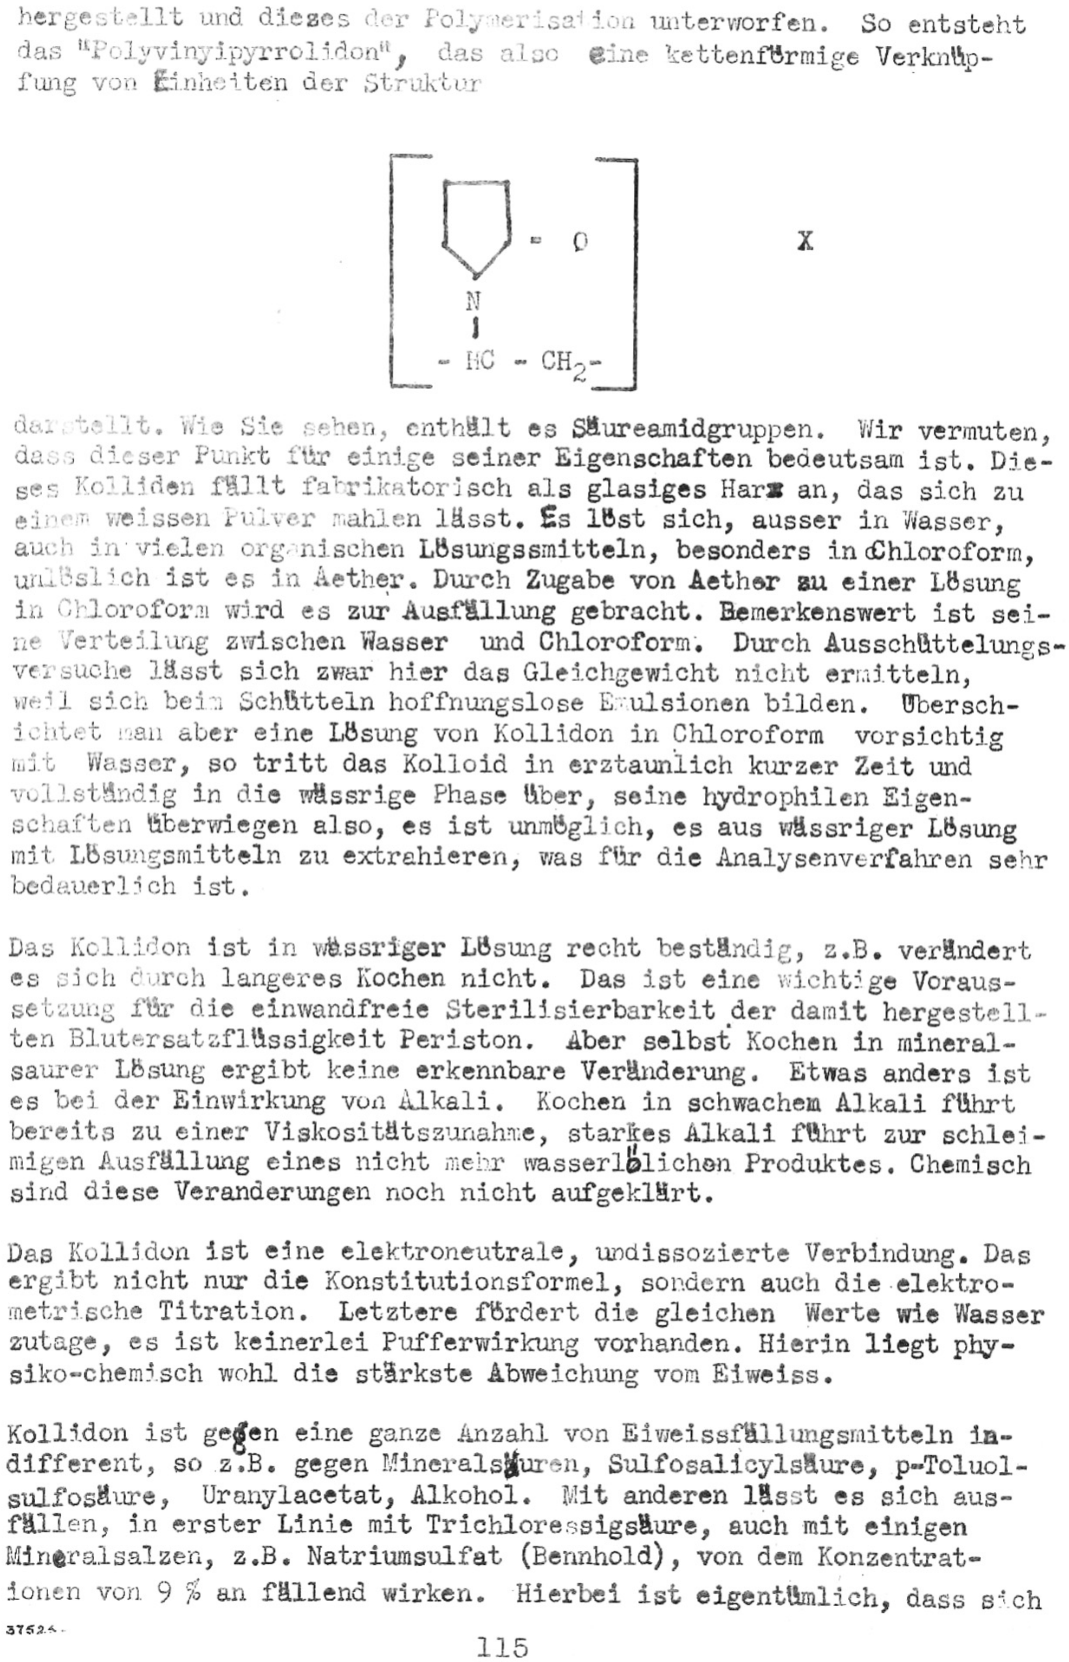


hergestellt und dieses der Polymerisation unterworfen. So entsteht das "Polyvinyipyrrolidon", das also eine kettenförmige Verknüpfung von Einheiten der Struktur

darstellt. Wie Sie sehen, enthält es Säureamidgruppen. Wir vermuten, dass dieser Punkt für einige seiner Eigenschaften bedeutsam ist. Dieses Kolliden fällt fabrikatorisch als glasiges Harz an, das sich zu einem weissen Pulver mahlen lässt. Es löst sich, ausser in Wasser, auch in vielen organischen Lösungssmitteln, besonders in Chloroform, unlöslich ist es in Aether. Durch Zugabe von Aether zu einer Lösung in Chloroform wird es zur Ausfällung gebracht. Bemerkenswert ist seine Verteilung zwischen Wasser und Chloroform. Durch Ausschüttelungsversuche lässt sich zwar hier das Gleichgewicht nicht ermitteln, weil sich beim Schütteln hoffnungslose Emulsionen bilden. Überschichtet man aber eine Lösung von Kollidon in Chloroform vorsichtig mit Wasser, so tritt das Kolloid in erztaunlich kurzer Zeit und vollständig in die wässrige Phase über, seine hydrophilen Eigenschaften überwiegen also, es ist unmöglich, es aus wässriger Lösung mit Lösungsmitteln zu extrahieren, was für die Analysenverfahren sehr bedauerlich ist.

Das Kollidon ist in wässriger Lösung recht beständig, z.B. verändert es sich durch langeres Kochen nicht. Das ist eine wichtige Voraussetzung für die einwandfreie Sterilisierbarkeit der damit hergestellten Blutersatzflüssigkeit Periston. Aber selbst Kochen in mineralsaurer Lösung ergibt keine erkennbare Veränderung. Etwas anders ist es bei der Einwirkung von Alkali. Kochen in schwachem Alkali führt bereits zu einer Viskositätszunahme, starkes Alkali führt zur schleimigen Ausfällung eines nicht mehr wasserlöslichen Produktes. Chemisch sind diese Veranderungen noch nicht aufgeklärt.

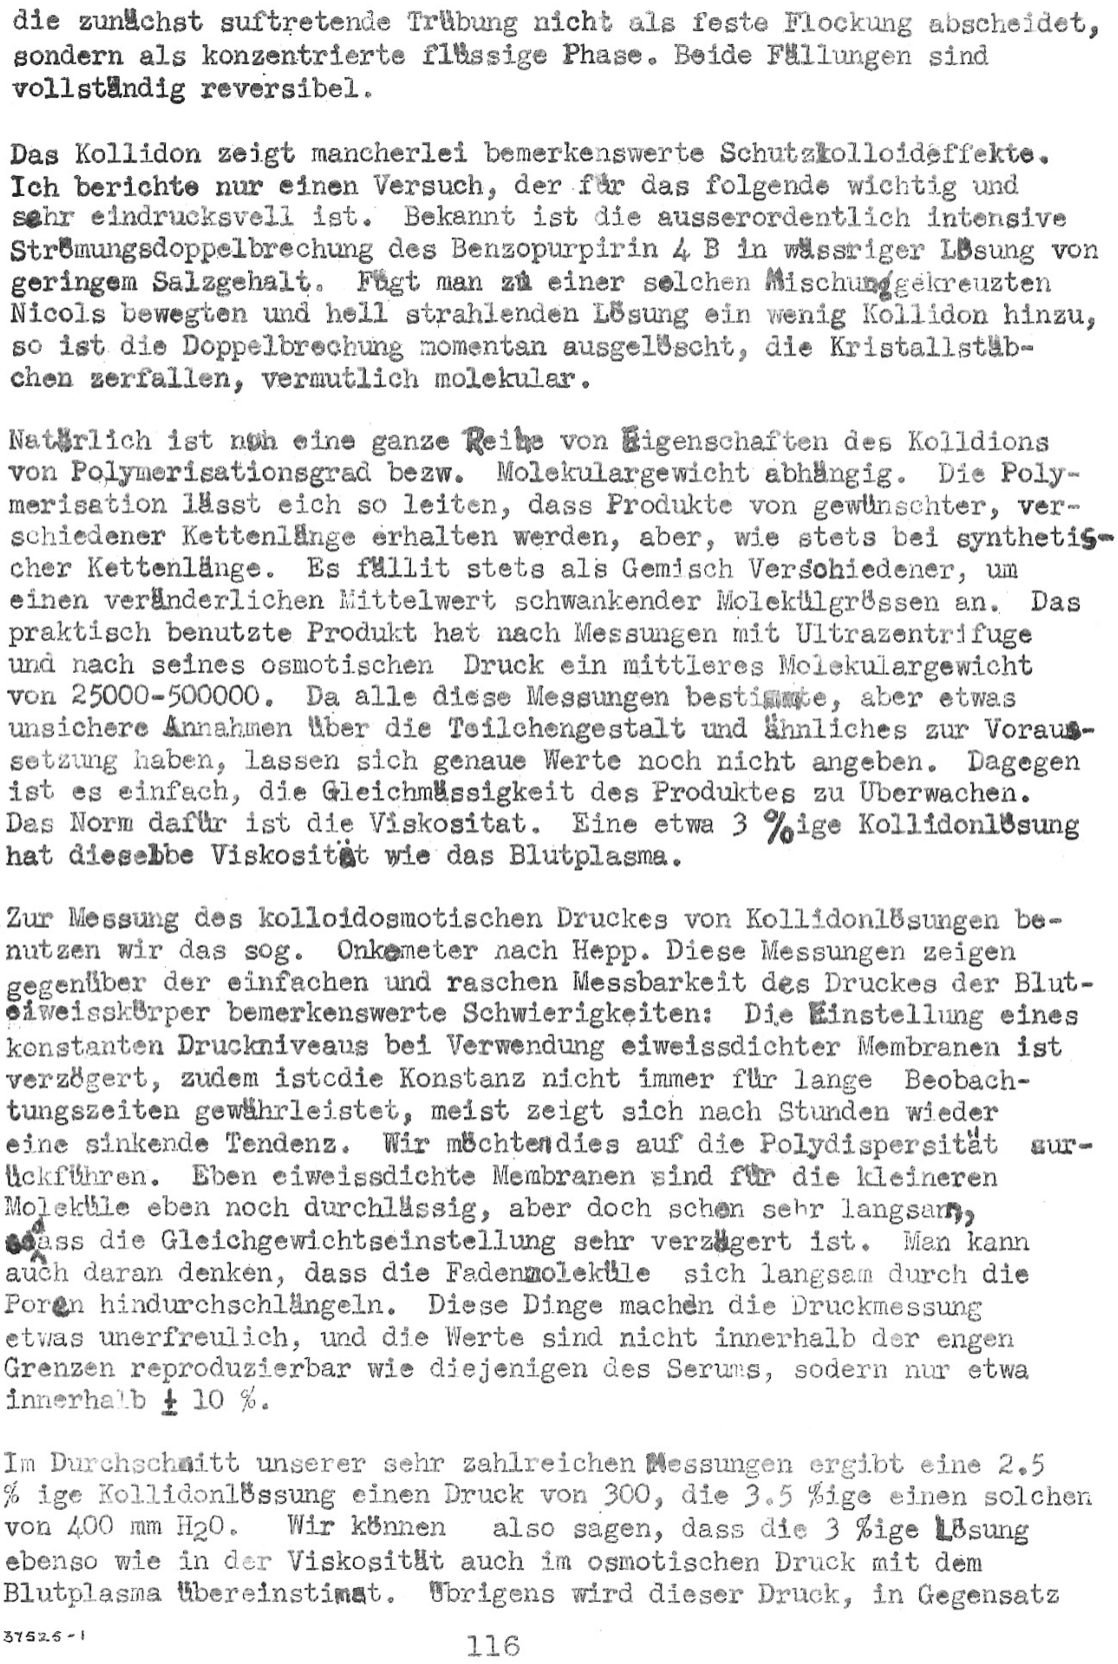
Das Kollidon ist eine elektroneutrale, undissozierte Verbindung. Das ergibt nicht nur die Konstitutionsformel, sondern auch die elektrometrische Titration. Letztere fördert die gleichen Werte wie Wasser zutage, es ist keinerlei Pufferwirkung vorhanden. Hierin liegt physiko-chemisch wohl die stärkste Abweichung vom Eiweiss.

Kollidon ist gegen eine ganze Anzahl von Eiweissfällungsmitteln indifferent, so z.B. gegen Mineralsäuren, Sulfosalicylsäure, p-Toluolsulfosäure, Uranylacetat, Alkohol. Mit anderen lässt es sich ausfällen, in erster Linie mit Trichloressigsäure, auch mit einigen Mineralsalzen, z.B. Natriumsulfat (Bennhold), von dem Konzentrationen von 9 % an fällend wirken. Hierbei ist eigentümlich, dass sich

37525-

115

Figure A.87: Information on periston [CIOS XXV-54].



die zunächst auftretende Trübung nicht als feste Flockung abscheidet, sondern als konzentrierte flüssige Phase. Beide Fällungen sind vollständig reversibel.

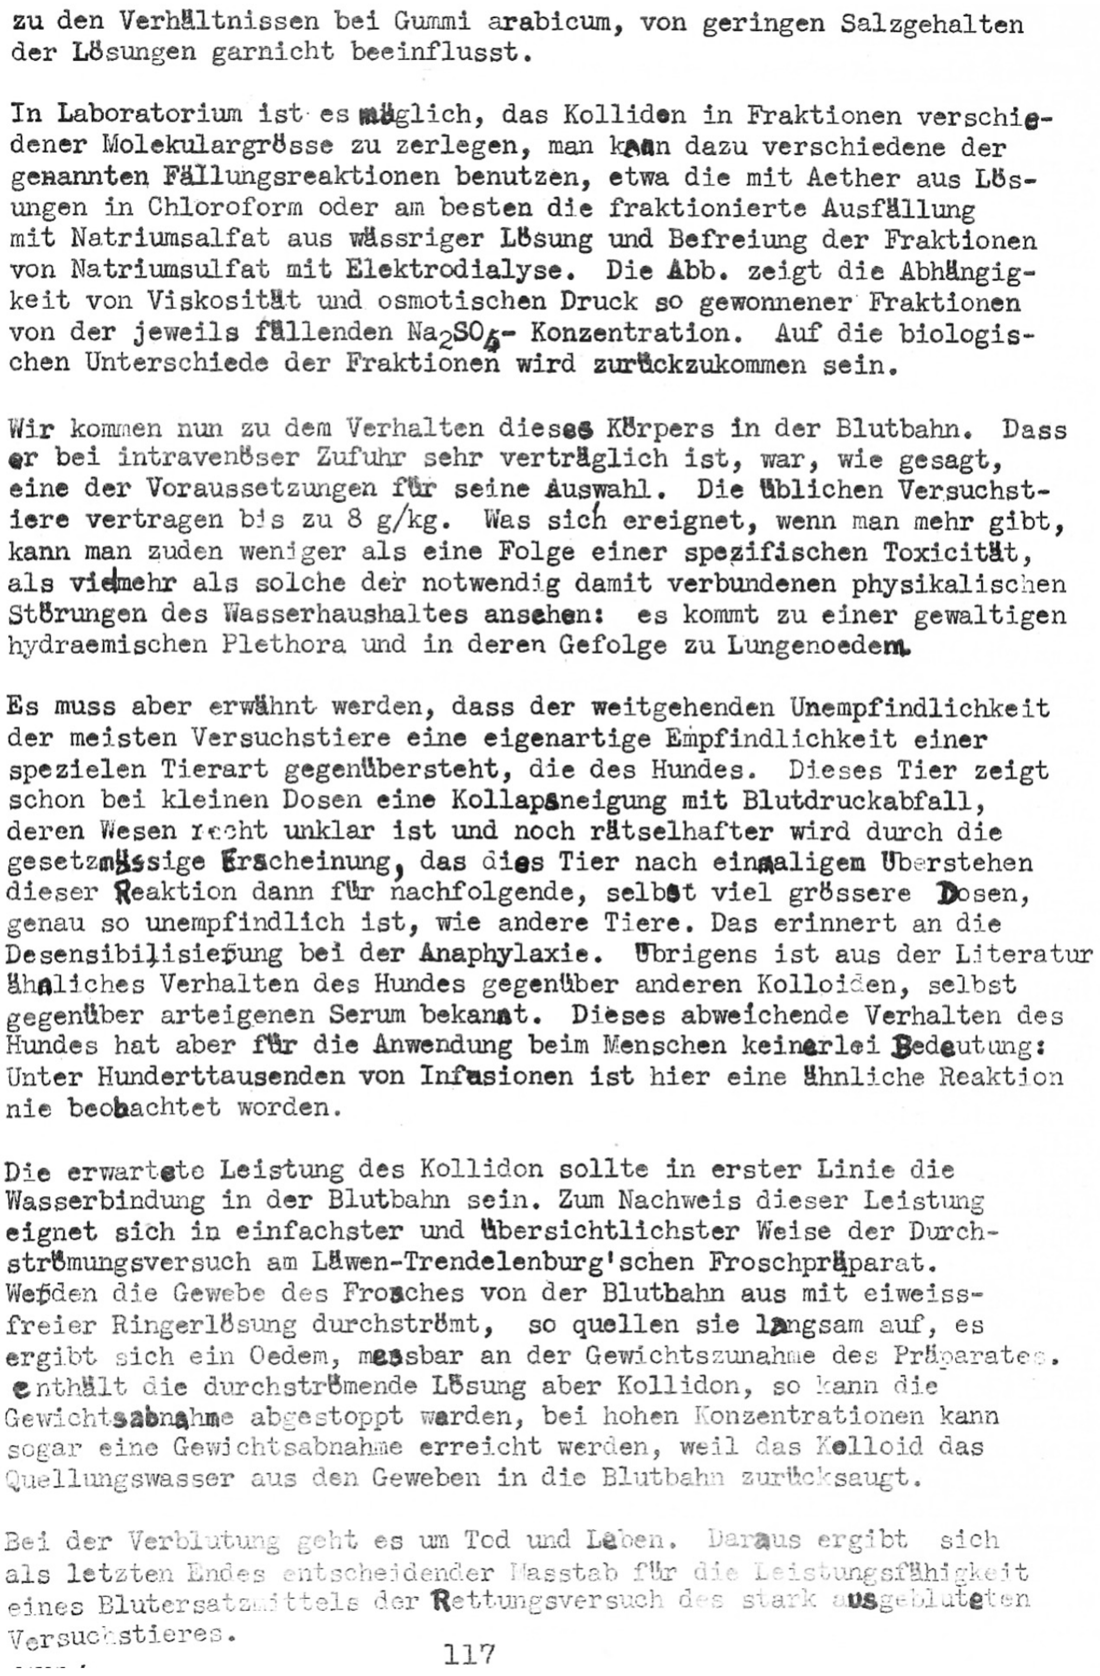
Das Kollidon zeigt mancherlei bemerkenswerte Schutzkolloideffekte. Ich berichte nur einen Versuch, der für das folgende wichtig und sehr eindrucksvell ist. Bekannt ist die ausserordentlich intensive Strömungsdoppelbrechung des Benzopurpirin 4 B in wässriger Lösung von geringem Salzgehalt. Fügt man zu einer solchen Mischung gekreuzten Nicols bewegten und hell strahlenden Lösung ein wenig Kollidon hinzu, so ist die Doppelbrechung momentan ausgelöscht, die Kristallstäbchen zerfallen, vermutlich molekular.

Natürlich ist noch eine ganze Reihe von Eigenschaften des Kolldions von Polymerisationsgrad bezw. Molekulargewicht abhängig. Die Polymerisation lässt eich so leiten, dass Produkte von gewünschter, verschiedener Kettenlänge erhalten werden, aber, wie stets bei synthetischer Kettenlänge. Es fällit stets als Gemisch Verschiedener, um einen veränderlichen Mittelwert schwankender Molekülgrössen an. Das praktisch benutzte Produkt hat nach Messungen mit Ultrazentrifuge und nach seines osmotischen Druck ein mittleres Molekulargewicht von 25000-500000. Da alle diese Messungen bestimmte, aber etwas unsichere Annahmen über die Teilchengestalt und ähnliches zur Voraussetzung haben, lassen sich genaue Werte noch nicht angeben. Dagegen ist es einfach, die Gleichmässigkeit des Produktes zu Überwachen. Das Norm dafür ist die Viskositat. Eine etwa 3 %ige Kollidonlösung hat dieselbe Viskosität wie das Blutplasma.

Zur Messung des kolloidosmotischen Druckes von Kollidonlösungen benutzen wir das sog. Onkometer nach Hepp. Diese Messungen zeigen gegenüber der einfachen und raschen Messbarkeit des Druckes der Bluteiweisskörper bemerkenswerte Schwierigkeiten: Die Einstellung eines konstanten Druckniveaus bei Verwendung eiweissdichter Membranen ist verzögert, zudem istcdie Konstanz nicht immer für lange Beobachtungszeiten gewährleistet, meist zeigt sich nach Stunden wieder eine sinkende Tendenz. Wir möchten dies auf die Polydispersität zurückführen. Eben eiweissdichte Membranen sind für die kleineren Moleküle eben noch durchlässig, aber doch schon sehr langsam, dass die Gleichgewichtseinstellung sehr verzögert ist. Man kann auch daran denken, dass die Fadenmoleküle sich langsam durch die Poren hindurchschlängeln. Diese Dinge machen die Druckmessung etwas unerfreulich, und die Werte sind nicht innerhalb der engen Grenzen reproduzierbar wie diejenigen des Serums, sodern nur etwa innerhalb ± 10 %.

Im Durchschnitt unserer sehr zahlreichen Messungen ergibt eine 2.5 % ige Kollidonlössung einen Druck von 300, die 3.5 %ige einen solchen von 400 mm H_2O. Wir können also sagen, dass die 3 %ige Lösung ebenso wie in der Viskosität auch im osmotischen Druck mit dem Blutplasma übereinstimmt. Übrigens wird dieser Druck, in Gegensatz

Figure A.88: Information on periston [CIOS XXV-54].



zu den Verhältnissen bei Gummi arabicum, von geringen Salzgehalten der Lösungen garnicht beeinflusst.

In Laboratorium ist es möglich, das Kolliden in Fraktionen verschiedener Molekulargrösse zu zerlegen, man kann dazu verschiedene der genannten Fällungsreaktionen benutzen, etwa die mit Aether aus Lösungen in Chloroform oder am besten die fraktionierte Ausfällung mit Natriumsalfat aus wässriger Lösung und Befreiung der Fraktionen von Natriumsulfat mit Elektrodialyse. Die Abb. zeigt die Abhängigkeit von Viskosität und osmotischen Druck so gewonnener Fraktionen von der jeweils fällenden Na_2SO_4- Konzentration. Auf die biologischen Unterschiede der Fraktionen wird zurückzukommen sein.

Wir kommen nun zu dem Verhalten dieses Körpers in der Blutbahn. Dass er bei intravenöser Zufuhr sehr verträglich ist, war, wie gesagt, eine der Voraussetzungen für seine Auswahl. Die üblichen Versuchstiere vertragen bis zu 8 g/kg. Was sich ereignet, wenn man mehr gibt, kann man zuden weniger als eine Folge einer spezifischen Toxicität, als vielmehr als solche der notwendig damit verbundenen physikalischen Störungen des Wasserhaushaltes ansehen: es kommt zu einer gewaltigen hydraemischen Plethora und in deren Gefolge zu Lungenoedem.

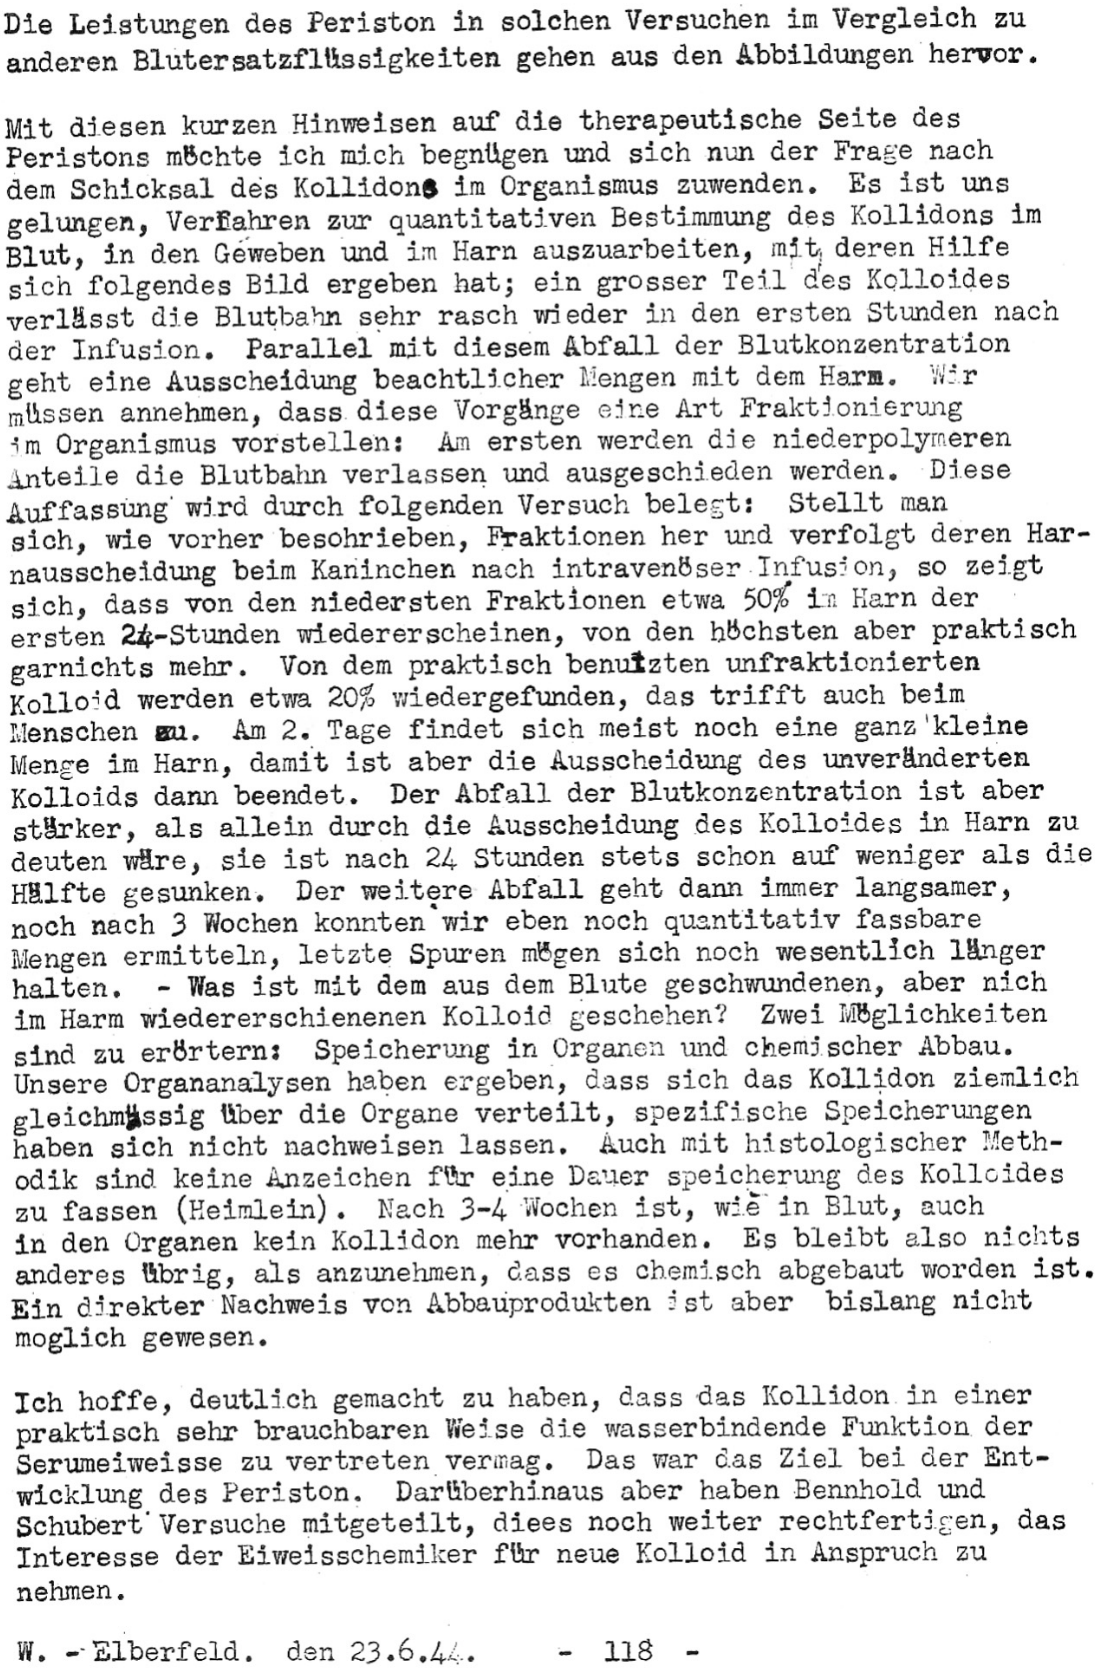
Es muss aber erwähnt werden, dass der weitgehenden Unempfindlichkeit der meisten Versuchstiere eine eigenartige Empfindlichkeit einer spezielen Tierart gegenübersteht, die des Hundes. Dieses Tier zeigt schon bei kleinen Dosen eine Kollapsneigung mit Blutdruckabfall, deren Wesen recht unklar ist und noch rätselhafter wird durch die gesetzmässige Erscheinung, das dies Tier nach einmaligem Überstehen dieser Reaktion dann für nachfolgende, selbst viel grössere Dosen, genau so unempfindlich ist, wie andere Tiere. Das erinnert an die Desensibilisierung bei der Anaphylaxie. Übrigens ist aus der Literatur ähnliches Verhalten des Hundes gegenüber anderen Kolloiden, selbst gegenüber arteigenen Serum bekannt. Dieses abweichende Verhalten des Hundes hat aber für die Anwendung beim Menschen keinerlei Bedeutung: Unter Hunderttausenden von Infusionen ist hier eine ähnliche Reaktion nie beobachtet worden.

Die erwartete Leistung des Kollidon sollte in erster Linie die Wasserbindung in der Blutbahn sein. Zum Nachweis dieser Leistung eignet sich in einfachster und übersichtlichster Weise der Durchströmungsversuch am Läwen-Trendelenburg'schen Froschpräparat. Werden die Gewebe des Frosches von der Blutbahn aus mit eiweissfreier Ringerlösung durchströmt, so quellen sie langsam auf, es ergibt sich ein Oedem, messbar an der Gewichtszunahme des Präparates. enthält die durchströmende Lösung aber Kollidon, so kann die Gewichtsabnahme abgestoppt warden, bei hohen Konzentrationen kann sogar eine Gewichtsabnahme erreicht werden, weil das Kolloid das Quellungswasser aus den Geweben in die Blutbahn zurücksaugt.

Bei der Verblutung geht es um Tod und Leben. Daraus ergibt sich als letzten Endes entscheidender Masstab für die Leistungsfähigkeit eines Blutersatzmittels der Rettungsversuch des stark ausgebluteten Versuchstieres.

117

Figure A.89: Information on periston [CIOS XXV-54].



Die Leistungen des Periston in solchen Versuchen im Vergleich zu anderen Blutersatzflüssigkeiten gehen aus den Abbildungen hervor.

Mit diesen kurzen Hinweisen auf die therapeutische Seite des Peristons möchte ich mich begnügen und sich nun der Frage nach dem Schicksal des Kollidons im Organismus zuwenden. Es ist uns gelungen, Verfahren zur quantitativen Bestimmung des Kollidons im Blut, in den Geweben und im Harn auszuarbeiten, mit deren Hilfe sich folgendes Bild ergeben hat; ein grosser Teil des Kolloides verlässt die Blutbahn sehr rasch wieder in den ersten Stunden nach der Infusion. Parallel mit diesem Abfall der Blutkonzentration geht eine Ausscheidung beachtlicher Mengen mit dem Harm. Wir müssen annehmen, dass diese Vorgänge eine Art Fraktionierung im Organismus vorstellen: Am ersten werden die niederpolymeren Anteile die Blutbahn verlassen und ausgeschieden werden. Diese Auffassung wird durch folgenden Versuch belegt: Stellt man sich, wie vorher beschrieben, Fraktionen her und verfolgt deren Harnausscheidung beim Kaninchen nach intravenöser Infusion, so zeigt sich, dass von den niedersten Fraktionen etwa 50% im Harn der ersten 24-Stunden wiedererscheinen, von den höchsten aber praktisch garnichts mehr. Von dem praktisch benutzten unfraktionierten Kolloid werden etwa 20% wiedergefunden, das trifft auch beim Menschen zu. Am 2. Tage findet sich meist noch eine ganz kleine Menge im Harn, damit ist aber die Ausscheidung des unveränderten Kolloids dann beendet. Der Abfall der Blutkonzentration ist aber stärker, als allein durch die Ausscheidung des Kolloides in Harn zu deuten wäre, sie ist nach 24 Stunden stets schon auf weniger als die Hälfte gesunken. Der weitere Abfall geht dann immer langsamer, noch nach 3 Wochen konnten wir eben noch quantitativ fassbare Mengen ermitteln, letzte Spuren mögen sich noch wesentlich länger halten. - Was ist mit dem aus dem Blute geschwundenen, aber nich im Harm wiedererschienenen Kolloid geschehen? Zwei Möglichkeiten sind zu erörtern: Speicherung in Organen und chemischer Abbau. Unsere Organanalysen haben ergeben, dass sich das Kollidon ziemlich gleichmässig über die Organe verteilt, spezifische Speicherungen haben sich nicht nachweisen lassen. Auch mit histologischer Methodik sind keine Anzeichen für eine Dauer speicherung des Kolloides zu fassen (Heimlein). Nach 3-4 Wochen ist, wie in Blut, auch in den Organen kein Kollidon mehr vorhanden. Es bleibt also nichts anderes übrig, als anzunehmen, dass es chemisch abgebaut worden ist. Ein direkter Nachweis von Abbauprodukten ist aber bislang nicht moglich gewesen.

Ich hoffe, deutlich gemacht zu haben, dass das Kollidon in einer praktisch sehr brauchbaren Weise die wasserbindende Funktion der Serumeiweisse zu vertreten vermag. Das war das Ziel bei der Entwicklung des Periston. Darüberhinaus aber haben Bennhold und Schubert Versuche mitgeteilt, diees noch weiter rechtfertigen, das Interesse der Eiweisschemiker für neue Kolloid in Anspruch zu nehmen.

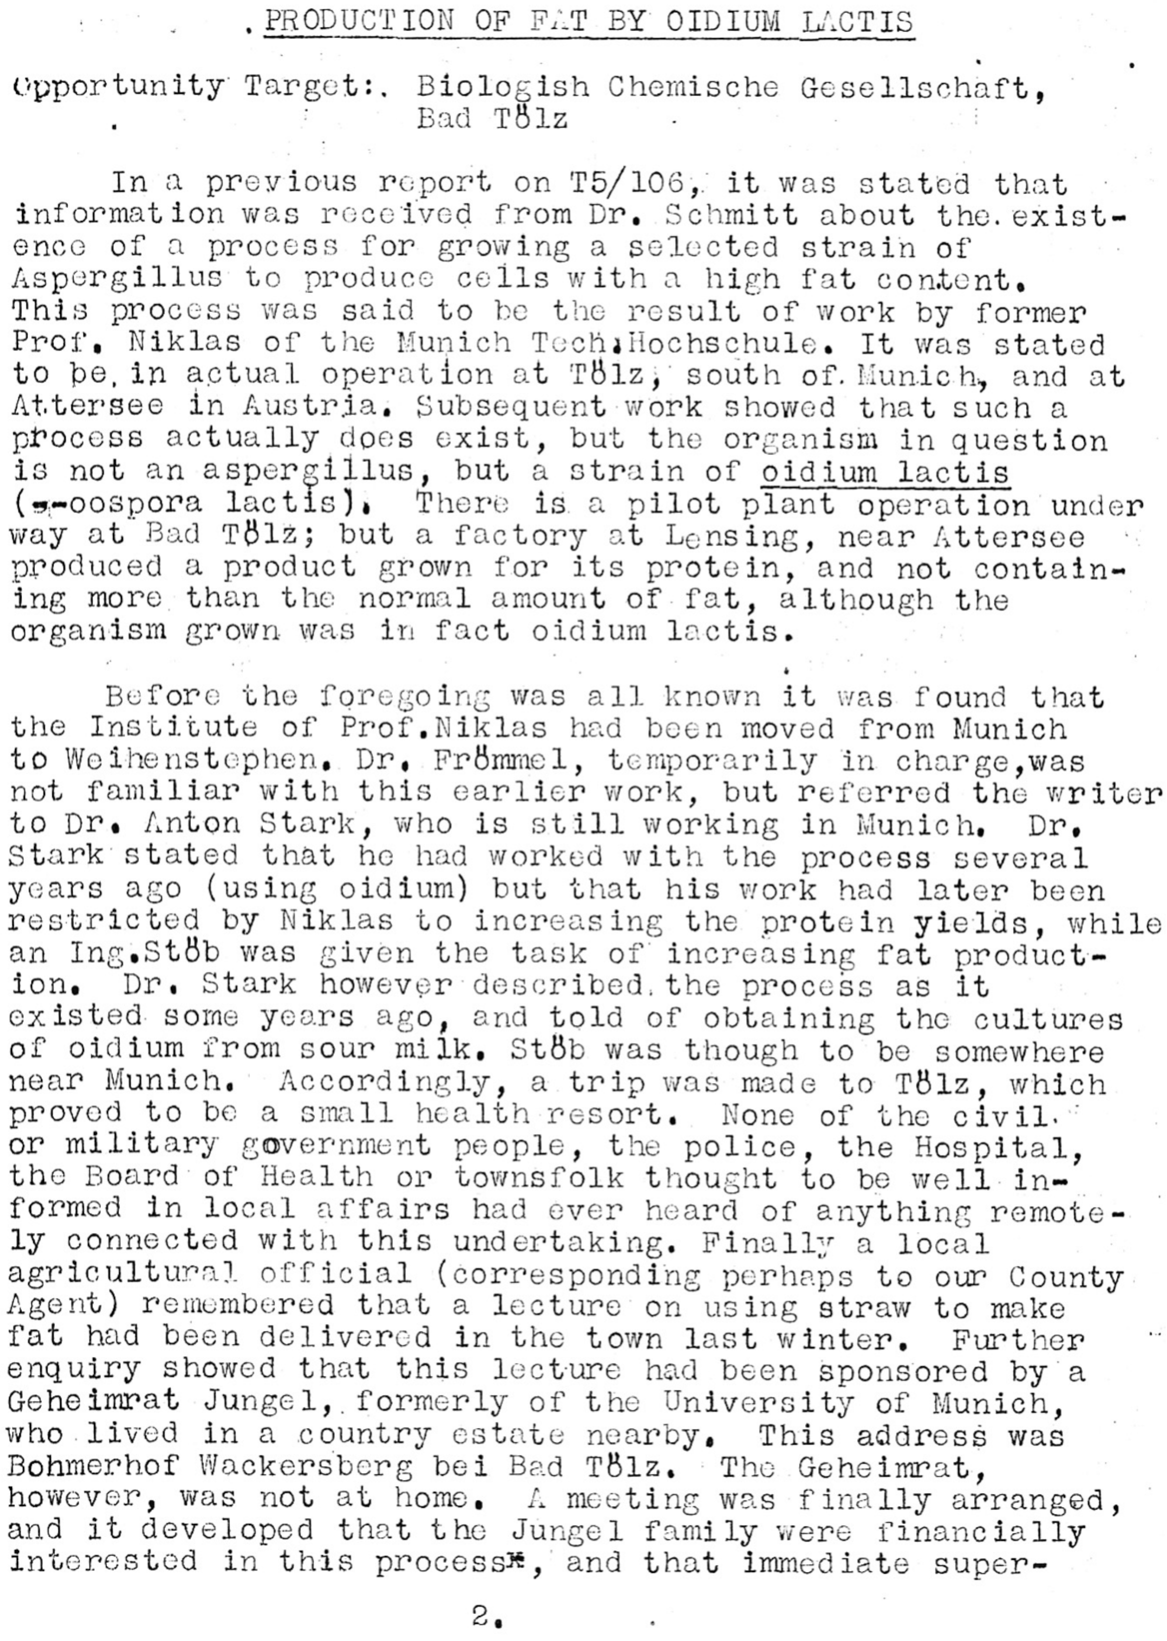
FIAT 371. ***Production of Fat by Oidium lactis.***

[See pp. 2431–2438 for some of the pages from this report.

See pp. 2439–2444 for examples of related patents by Hans Stöb.]



PRODUCTION OF FAT BY OIDIUM LACTIS

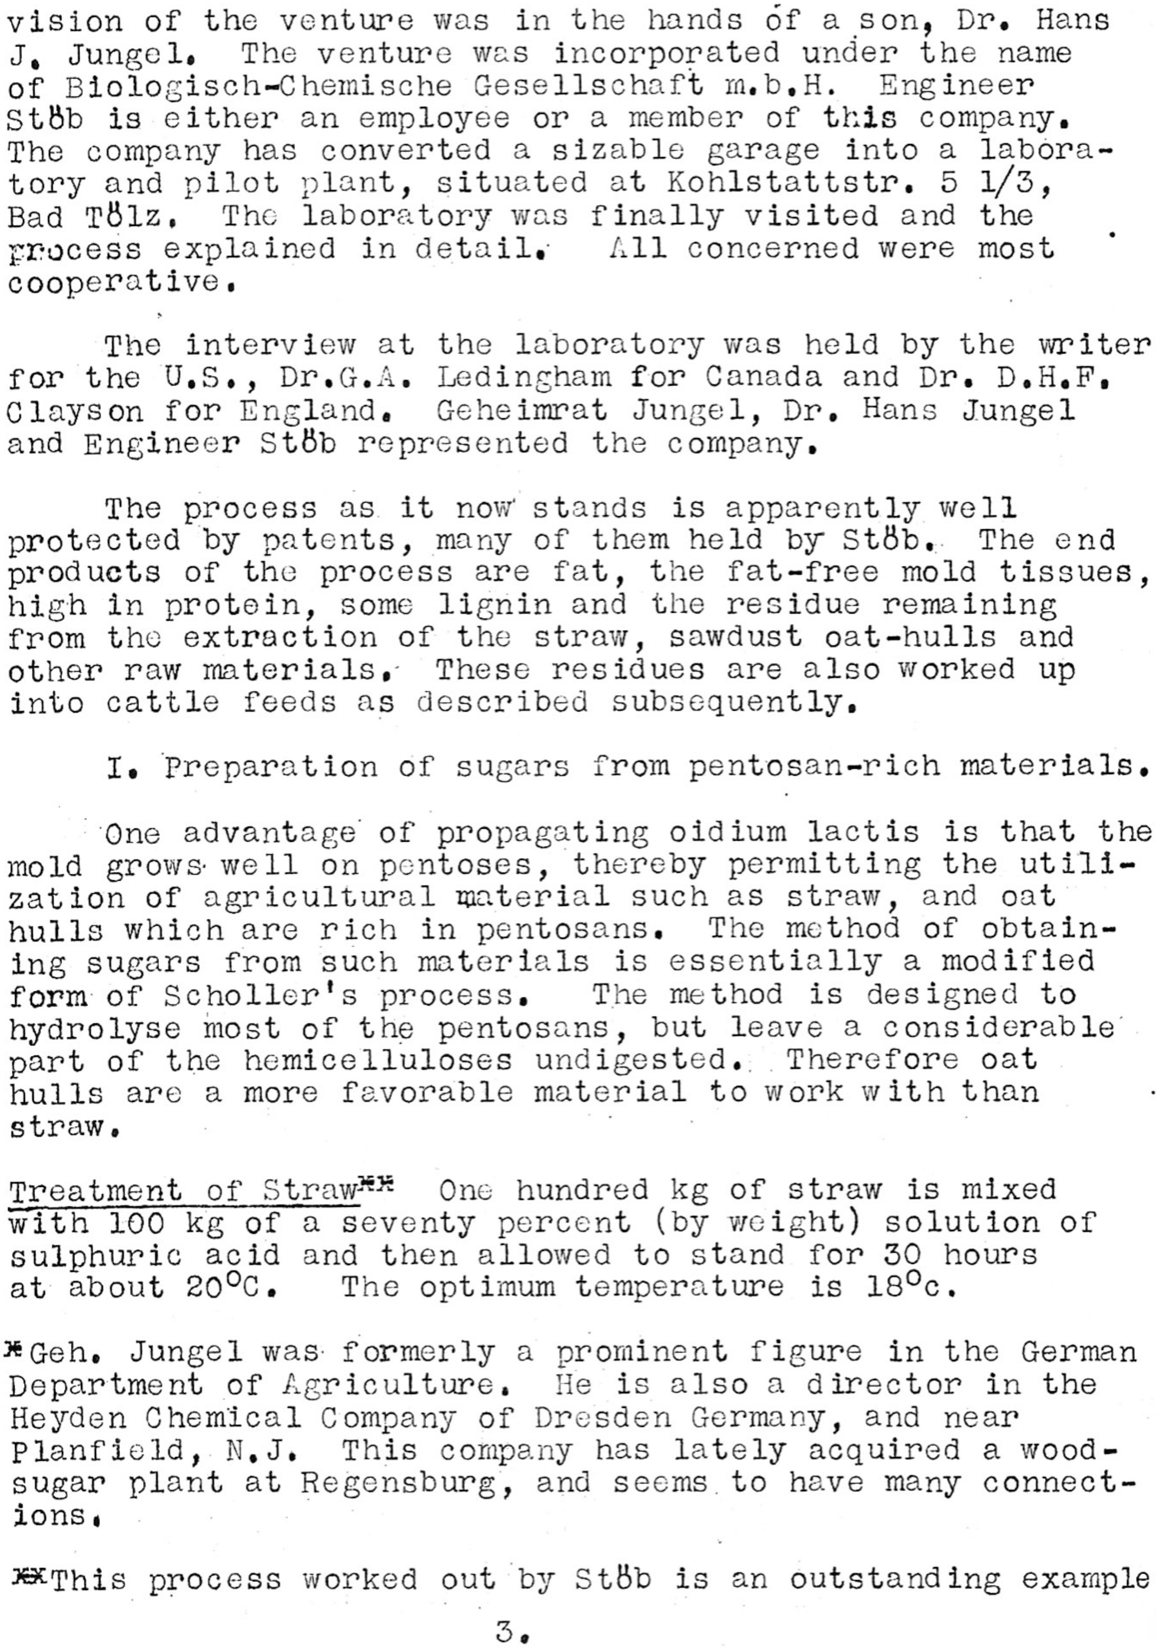
Opportunity Target:. Biologish Chemische Gesellschaft,
Bad Tölz

In a previous report on T5/106, it was stated that information was received from Dr. Schmitt about the existence of a process for growing a selected strain of Aspergillus to produce cells with a high fat content. This process was said to be the result of work by former Prof. Niklas of the Munich Tech.Hochschule. It was stated to be in actual operation at Tölz, south of Munich, and at Attersee in Austria. Subsequent work showed that such a process actually does exist, but the organism in question is not an aspergillus, but a strain of oidium lactis (=oospora lactis). There is a pilot plant operation under way at Bad Tölz; but a factory at Lensing, near Attersee produced a product grown for its protein, and not containing more than the normal amount of fat, although the organism grown was in fact oidium lactis.

Before the foregoing was all known it was found that the Institute of Prof.Niklas had been moved from Munich to Weihenstephen. Dr. Frömmel, temporarily in charge,was not familiar with this earlier work, but referred the writer to Dr. Anton Stark, who is still working in Munich. Dr. Stark stated that he had worked with the process several years ago (using oidium) but that his work had later been restricted by Niklas to increasing the protein yields, while an Ing.Stöb was given the task of increasing fat production. Dr. Stark however described the process as it existed some years ago, and told of obtaining the cultures of oidium from sour milk. Stöb was though to be somewhere near Munich. Accordingly, a trip was made to Tölz, which proved to be a small health resort. None of the civil or military government people, the police, the Hospital, the Board of Health or townsfolk thought to be well informed in local affairs had ever heard of anything remotely connected with this undertaking. Finally a local agricultural official (corresponding perhaps to our County Agent) remembered that a lecture on using straw to make fat had been delivered in the town last winter. Further enquiry showed that this lecture had been sponsored by a Geheimrat Jungel, formerly of the University of Munich, who lived in a country estate nearby. This address was Bohmerhof Wackersberg bei Bad Tölz. The Geheimrat, however, was not at home. A meeting was finally arranged, and it developed that the Jungel family were financially interested in this process*, and that immediate super-

2.

Figure A.91: Production of fat by *Oidium lactis* [FIAT 371].



vision of the venture was in the hands of a son, Dr. Hans J. Jungel. The venture was incorporated under the name of Biologisch-Chemische Gesellschaft m.b.H. Engineer Stöb is either an employee or a member of this company. The company has converted a sizable garage into a laboratory and pilot plant, situated at Kohlstattstr. 5 1/3, Bad Tölz. The laboratory was finally visited and the process explained in detail. All concerned were most cooperative.

The interview at the laboratory was held by the writer for the U.S., Dr.G.A. Ledingham for Canada and Dr. D.H.F. Clayson for England. Geheimrat Jungel, Dr. Hans Jungel and Engineer Stöb represented the company.

The process as it now stands is apparently well protected by patents, many of them held by Stöb. The end products of the process are fat, the fat-free mold tissues, high in protein, some lignin and the residue remaining from the extraction of the straw, sawdust oat-hulls and other raw materials. These residues are also worked up into cattle feeds as described subsequently.

I. Preparation of sugars from pentosan-rich materials.

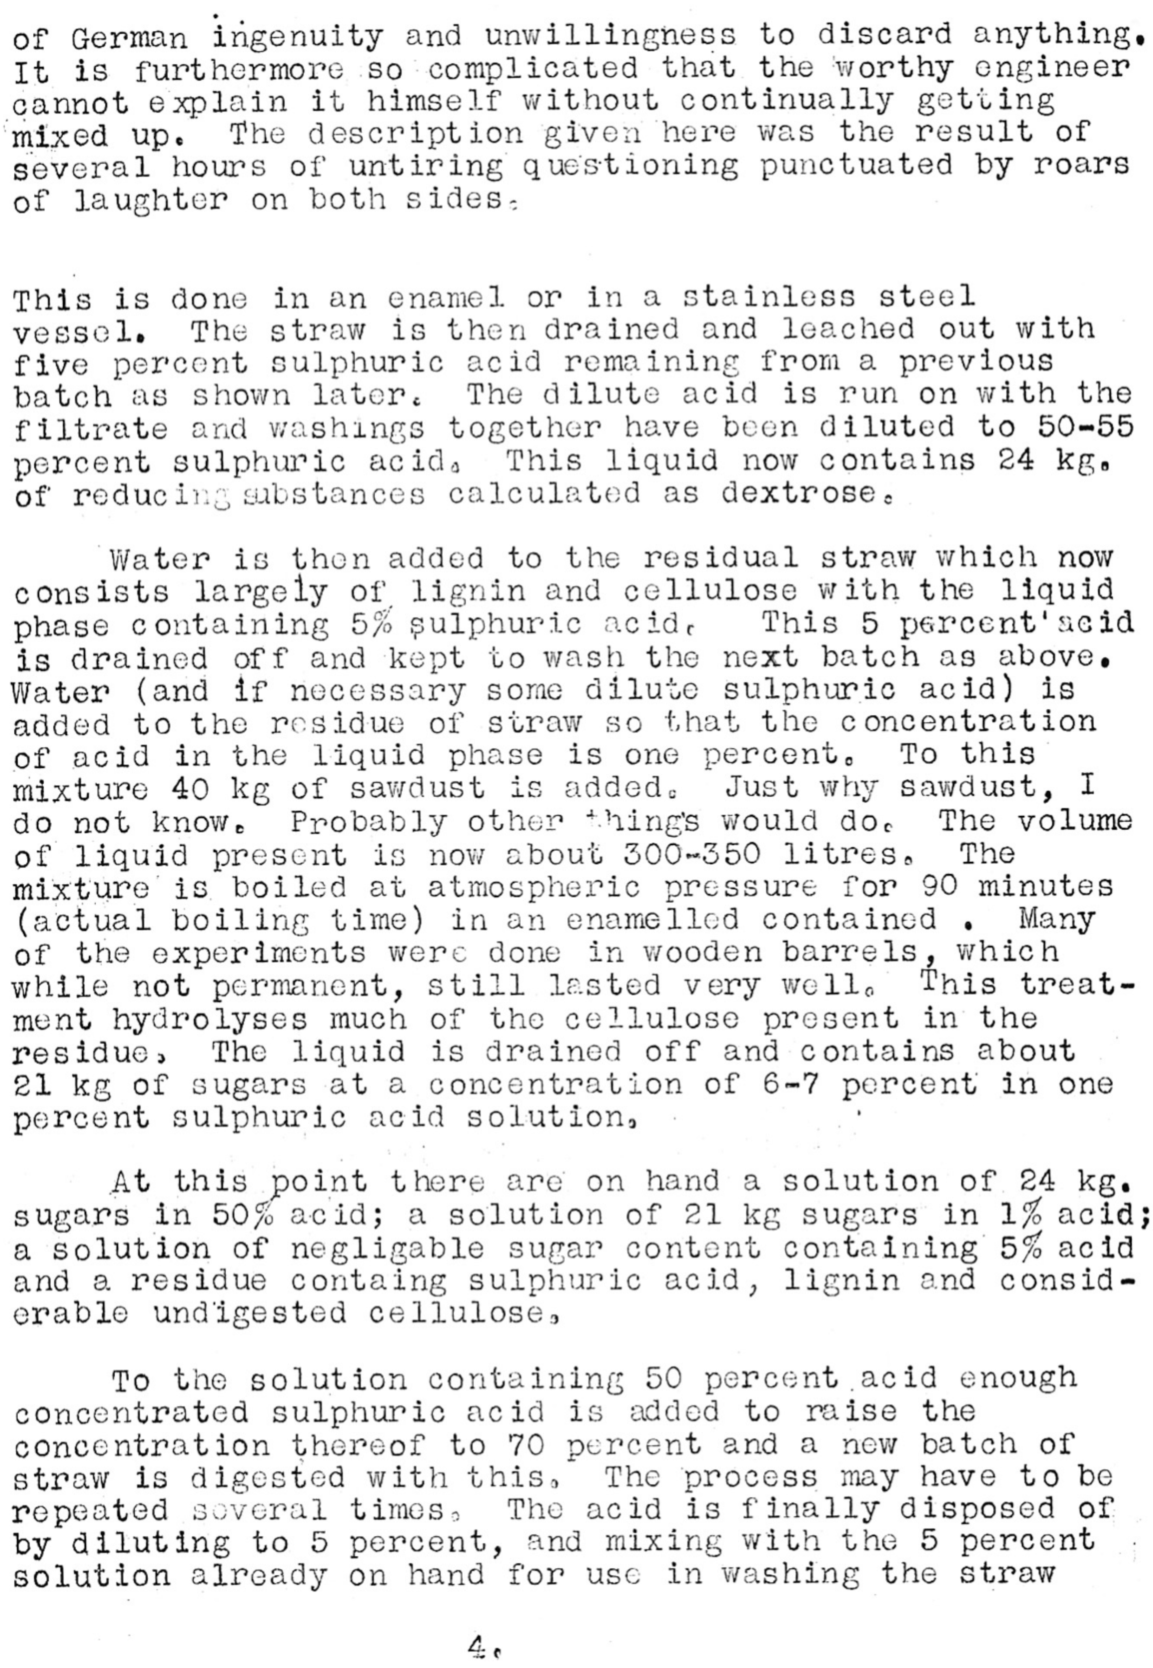
One advantage of propagating oidium lactis is that the mold grows well on pentoses, thereby permitting the utilization of agricultural material such as straw, and oat hulls which are rich in pentosans. The method of obtaining sugars from such materials is essentially a modified form of Scholler's process. The method is designed to hydrolyse most of the pentosans, but leave a considerable part of the hemicelluloses undigested. Therefore oat hulls are a more favorable material to work with than straw.

Treatment of Straw** One hundred kg of straw is mixed with 100 kg of a seventy percent (by weight) solution of sulphuric acid and then allowed to stand for 30 hours at about 20°C. The optimum temperature is 18°c.

*Geh. Jungel was formerly a prominent figure in the German Department of Agriculture. He is also a director in the Heyden Chemical Company of Dresden Germany, and near Planfield, N.J. This company has lately acquired a wood-sugar plant at Regensburg, and seems to have many connections.

**This process worked out by Stöb is an outstanding example

Figure A.92: Production of fat by *Oidium lactis* [FIAT 371].



of German ingenuity and unwillingness to discard anything. It is furthermore so complicated that the worthy engineer cannot explain it himself without continually getting mixed up. The description given here was the result of several hours of untiring questioning punctuated by roars of laughter on both sides.

This is done in an enamel or in a stainless steel vessel. The straw is then drained and leached out with five percent sulphuric acid remaining from a previous batch as shown later. The dilute acid is run on with the filtrate and washings together have been diluted to 50-55 percent sulphuric acid. This liquid now contains 24 kg. of reducing substances calculated as dextrose.

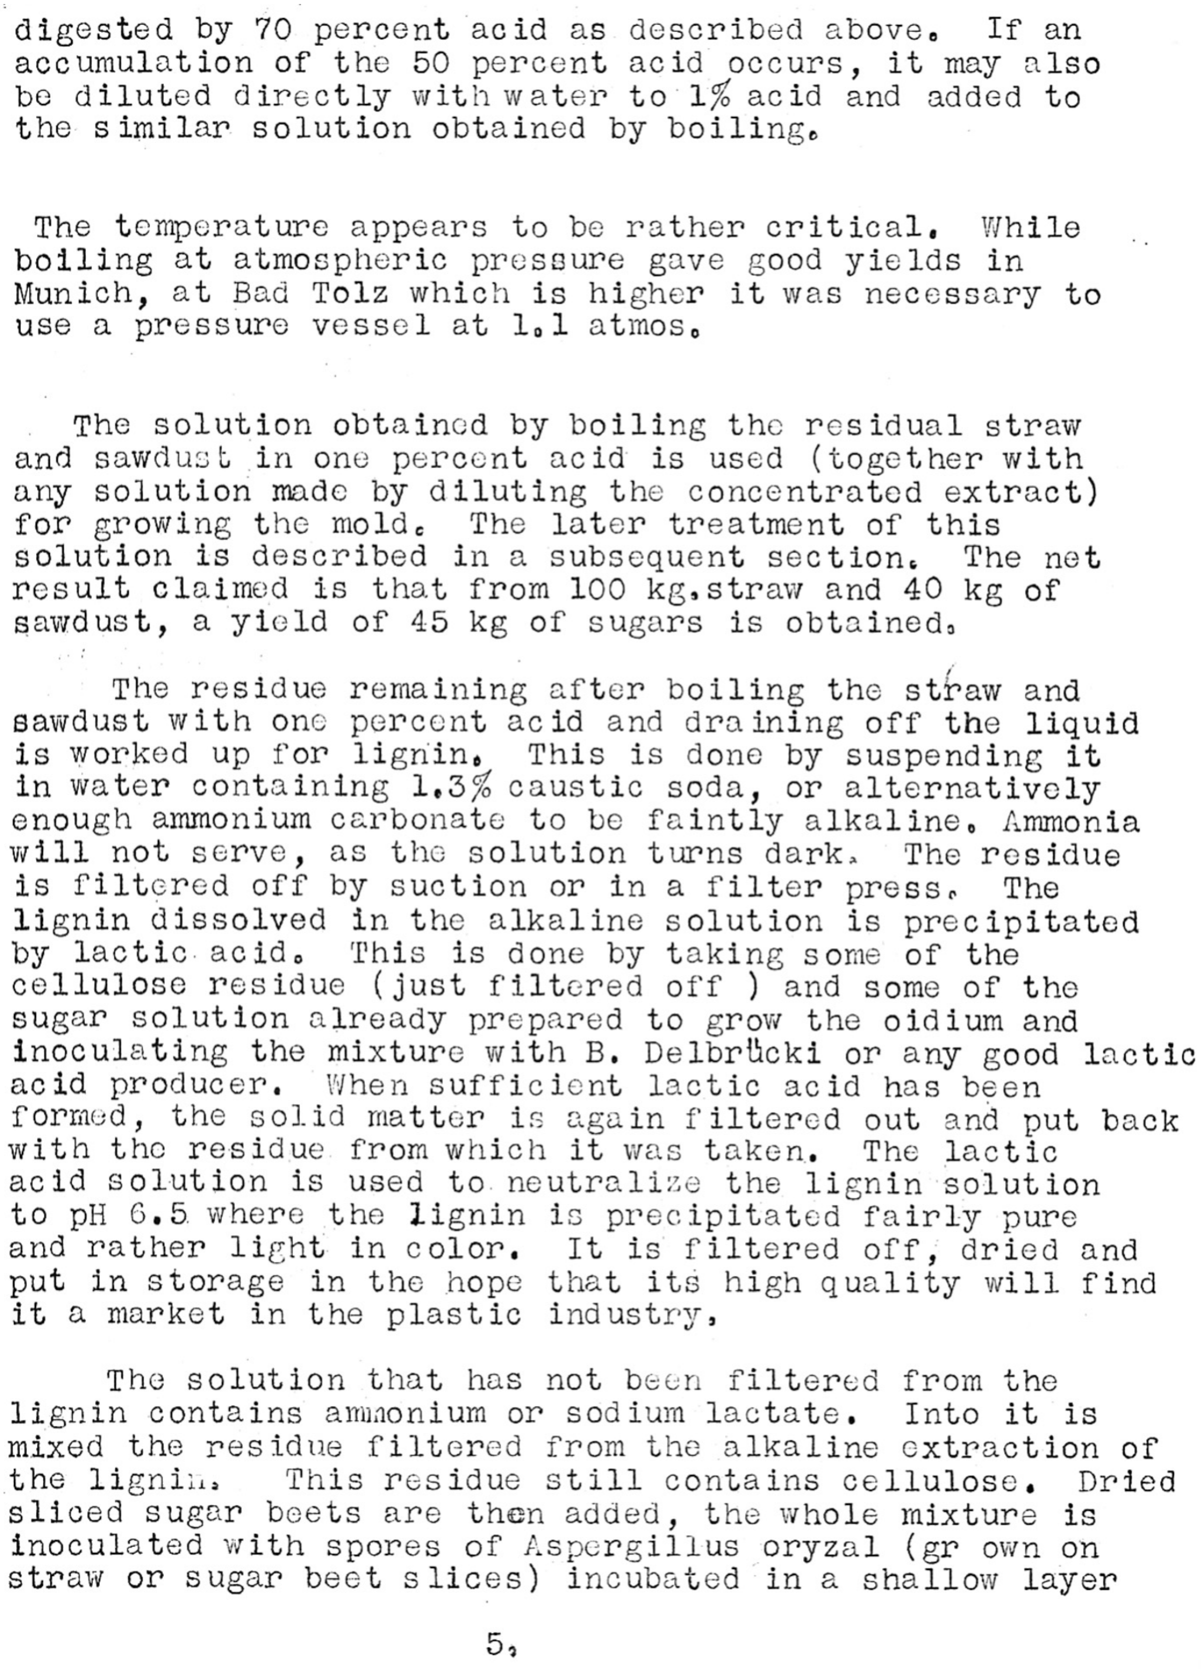
Water is then added to the residual straw which now consists largely of lignin and cellulose with the liquid phase containing 5% sulphuric acid. This 5 percent acid is drained off and kept to wash the next batch as above. Water (and if necessary some dilute sulphuric acid) is added to the residue of straw so that the concentration of acid in the liquid phase is one percent. To this mixture 40 kg of sawdust is added. Just why sawdust, I do not know. Probably other things would do. The volume of liquid present is now about 300-350 litres. The mixture is boiled at atmospheric pressure for 90 minutes (actual boiling time) in an enamelled contained . Many of the experiments were done in wooden barrels, which while not permanent, still lasted very well. This treatment hydrolyses much of the cellulose present in the residue. The liquid is drained off and contains about 21 kg of sugars at a concentration of 6-7 percent in one percent sulphuric acid solution.

At this point there are on hand a solution of 24 kg. sugars in 50% acid; a solution of 21 kg sugars in 1% acid; a solution of negligable sugar content containing 5% acid and a residue containg sulphuric acid, lignin and considerable undigested cellulose.

To the solution containing 50 percent acid enough concentrated sulphuric acid is added to raise the concentration thereof to 70 percent and a new batch of straw is digested with this. The process may have to be repeated several times. The acid is finally disposed of by diluting to 5 percent, and mixing with the 5 percent solution already on hand for use in washing the straw

4.

Figure A.93: Production of fat by *Oidium lactis* [FIAT 371].



digested by 70 percent acid as described above. If an accumulation of the 50 percent acid occurs, it may also be diluted directly with water to 1% acid and added to the similar solution obtained by boiling.

The temperature appears to be rather critical. While boiling at atmospheric pressure gave good yields in Munich, at Bad Tolz which is higher it was necessary to use a pressure vessel at 1.1 atmos.

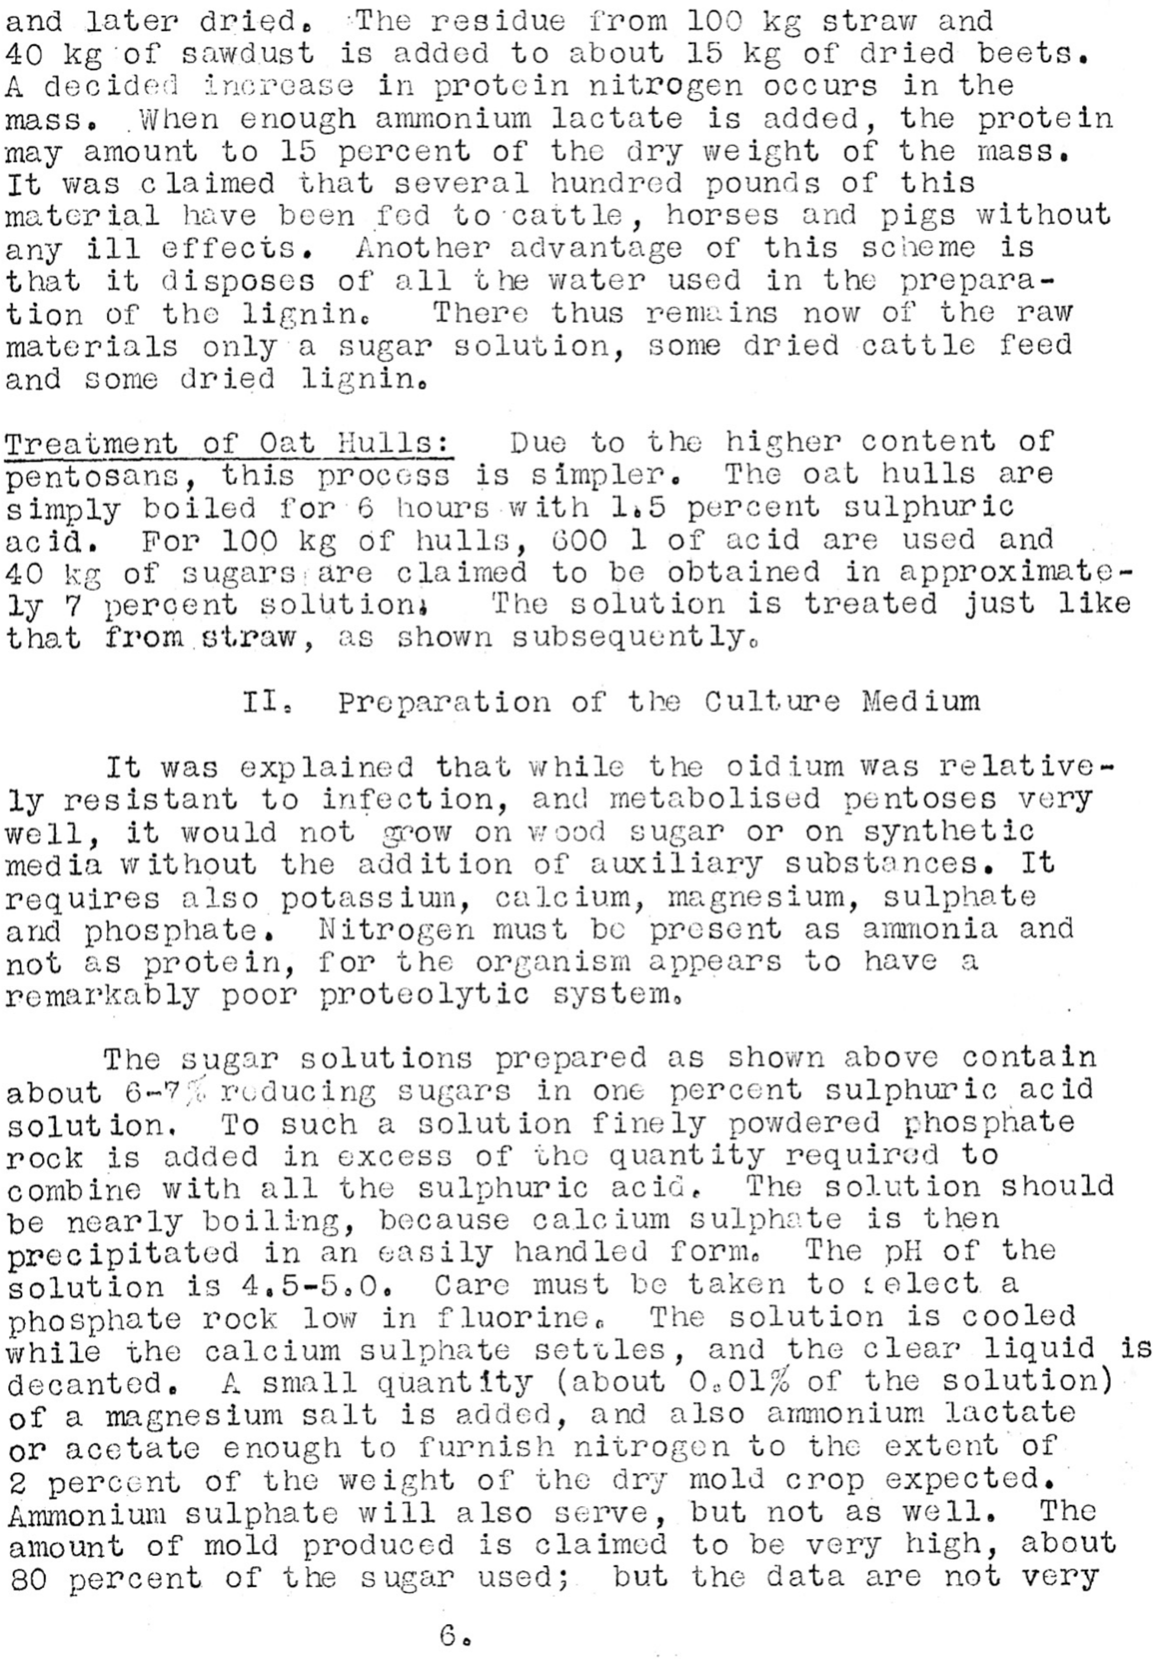
The solution obtained by boiling the residual straw and sawdust in one percent acid is used (together with any solution made by diluting the concentrated extract) for growing the mold. The later treatment of this solution is described in a subsequent section. The net result claimed is that from 100 kg, straw and 40 kg of sawdust, a yield of 45 kg of sugars is obtained.

The residue remaining after boiling the straw and sawdust with one percent acid and draining off the liquid is worked up for lignin. This is done by suspending it in water containing 1.3% caustic soda, or alternatively enough ammonium carbonate to be faintly alkaline. Ammonia will not serve, as the solution turns dark. The residue is filtered off by suction or in a filter press. The lignin dissolved in the alkaline solution is precipitated by lactic acid. This is done by taking some of the cellulose residue (just filtered off) and some of the sugar solution already prepared to grow the oidium and inoculating the mixture with B. Delbrücki or any good lactic acid producer. When sufficient lactic acid has been formed, the solid matter is again filtered out and put back with the residue from which it was taken. The lactic acid solution is used to neutralize the lignin solution to pH 6.5 where the lignin is precipitated fairly pure and rather light in color. It is filtered off, dried and put in storage in the hope that its high quality will find it a market in the plastic industry.

The solution that has not been filtered from the lignin contains ammonium or sodium lactate. Into it is mixed the residue filtered from the alkaline extraction of the lignin. This residue still contains cellulose. Dried sliced sugar beets are then added, the whole mixture is inoculated with spores of Aspergillus oryzal (gr own on straw or sugar beet slices) incubated in a shallow layer

5.

Figure A.94: Production of fat by *Oidium lactis* [FIAT 371].



and later dried. The residue from 100 kg straw and 40 kg of sawdust is added to about 15 kg of dried beets. A decided increase in protein nitrogen occurs in the mass. When enough ammonium lactate is added, the protein may amount to 15 percent of the dry weight of the mass. It was claimed that several hundred pounds of this material have been fed to cattle, horses and pigs without any ill effects. Another advantage of this scheme is that it disposes of all the water used in the preparation of the lignin. There thus remains now of the raw materials only a sugar solution, some dried cattle feed and some dried lignin.

Treatment of Oat Hulls: Due to the higher content of pentosans, this process is simpler. The oat hulls are simply boiled for 6 hours with 1.5 percent sulphuric acid. For 100 kg of hulls, 600 l of acid are used and 40 kg of sugars are claimed to be obtained in approximately 7 percent solution. The solution is treated just like that from straw, as shown subsequently.

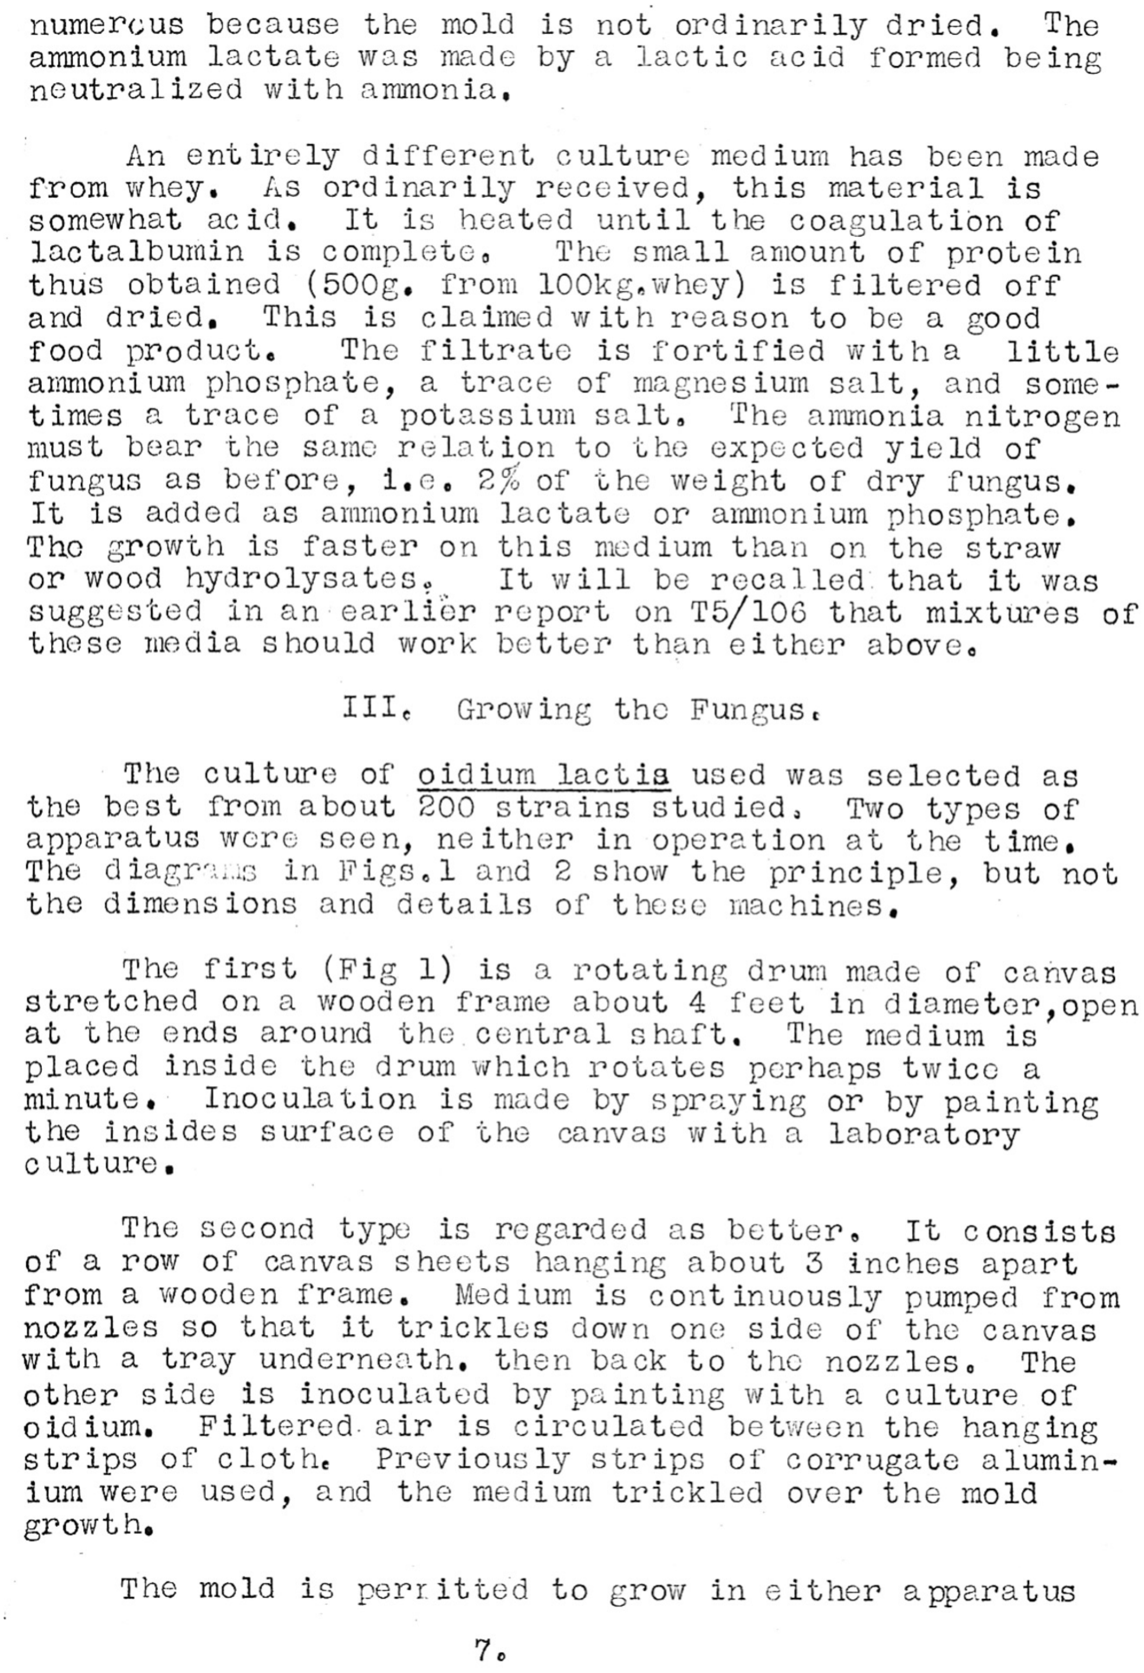
II. Preparation of the Culture Medium

It was explained that while the oidium was relatively resistant to infection, and metabolised pentoses very well, it would not grow on wood sugar or on synthetic media without the addition of auxiliary substances. It requires also potassium, calcium, magnesium, sulphate and phosphate. Nitrogen must be present as ammonia and not as protein, for the organism appears to have a remarkably poor proteolytic system.

The sugar solutions prepared as shown above contain about 6-7% reducing sugars in one percent sulphuric acid solution. To such a solution finely powdered phosphate rock is added in excess of the quantity required to combine with all the sulphuric acid. The solution should be nearly boiling, because calcium sulphate is then precipitated in an easily handled form. The pH of the solution is 4.5-5.0. Care must be taken to select a phosphate rock low in fluorine. The solution is cooled while the calcium sulphate settles, and the clear liquid is decanted. A small quantity (about 0.01% of the solution) of a magnesium salt is added, and also ammonium lactate or acetate enough to furnish nitrogen to the extent of 2 percent of the weight of the dry mold crop expected. Ammonium sulphate will also serve, but not as well. The amount of mold produced is claimed to be very high, about 80 percent of the sugar used; but the data are not very

6.

Figure A.95: Production of fat by *Oidium lactis* [FIAT 371].



numerous because the mold is not ordinarily dried. The ammonium lactate was made by a lactic acid formed being neutralized with ammonia.

An entirely different culture medium has been made from whey. As ordinarily received, this material is somewhat acid. It is heated until the coagulation of lactalbumin is complete. The small amount of protein thus obtained (500g. from 100kg.whey) is filtered off and dried. This is claimed with reason to be a good food product. The filtrate is fortified with a little ammonium phosphate, a trace of magnesium salt, and sometimes a trace of a potassium salt. The ammonia nitrogen must bear the same relation to the expected yield of fungus as before, i.e. 2% of the weight of dry fungus. It is added as ammonium lactate or ammonium phosphate. The growth is faster on this medium than on the straw or wood hydrolysates. It will be recalled that it was suggested in an earlier report on T5/106 that mixtures of these media should work better than either above.

III. Growing the Fungus.

The culture of oidium lactis used was selected as the best from about 200 strains studied. Two types of apparatus were seen, neither in operation at the time. The diagrams in Figs.1 and 2 show the principle, but not the dimensions and details of these machines.

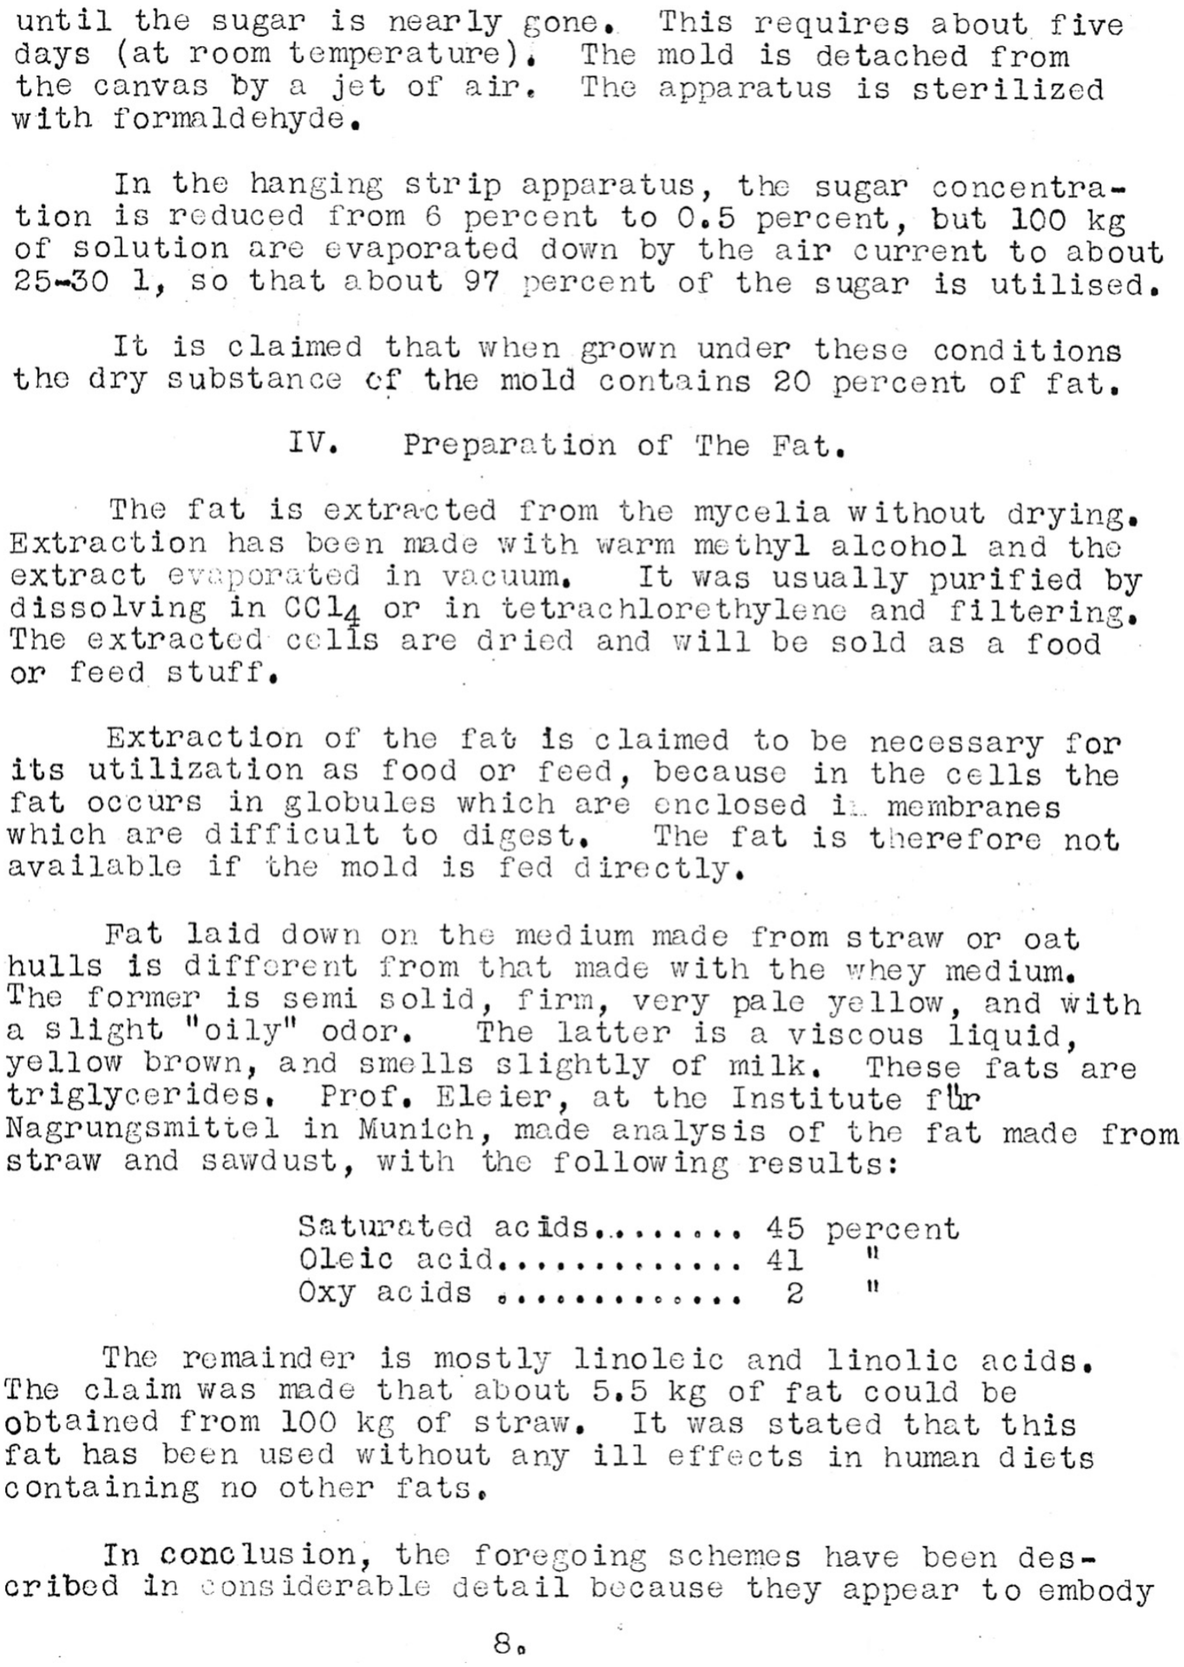
The first (Fig 1) is a rotating drum made of canvas stretched on a wooden frame about 4 feet in diameter,open at the ends around the central shaft. The medium is placed inside the drum which rotates perhaps twice a minute. Inoculation is made by spraying or by painting the insides surface of the canvas with a laboratory culture.

The second type is regarded as better. It consists of a row of canvas sheets hanging about 3 inches apart from a wooden frame. Medium is continuously pumped from nozzles so that it trickles down one side of the canvas with a tray underneath. then back to the nozzles. The other side is inoculated by painting with a culture of oidium. Filtered air is circulated between the hanging strips of cloth. Previously strips of corrugate aluminium were used, and the medium trickled over the mold growth.

The mold is permitted to grow in either apparatus

7.

Figure A.96: Production of fat by *Oidium lactis* [FIAT 371].



until the sugar is nearly gone. This requires about five days (at room temperature). The mold is detached from the canvas by a jet of air. The apparatus is sterilized with formaldehyde.

In the hanging strip apparatus, the sugar concentration is reduced from 6 percent to 0.5 percent, but 100 kg of solution are evaporated down by the air current to about 25-30 l, so that about 97 percent of the sugar is utilised.

It is claimed that when grown under these conditions the dry substance of the mold contains 20 percent of fat.

IV. Preparation of The Fat.

The fat is extracted from the mycelia without drying. Extraction has been made with warm methyl alcohol and the extract evaporated in vacuum. It was usually purified by dissolving in CCl_4 or in tetrachlorethylene and filtering. The extracted cells are dried and will be sold as a food or feed stuff.

Extraction of the fat is claimed to be necessary for its utilization as food or feed, because in the cells the fat occurs in globules which are enclosed in membranes which are difficult to digest. The fat is therefore not available if the mold is fed directly.

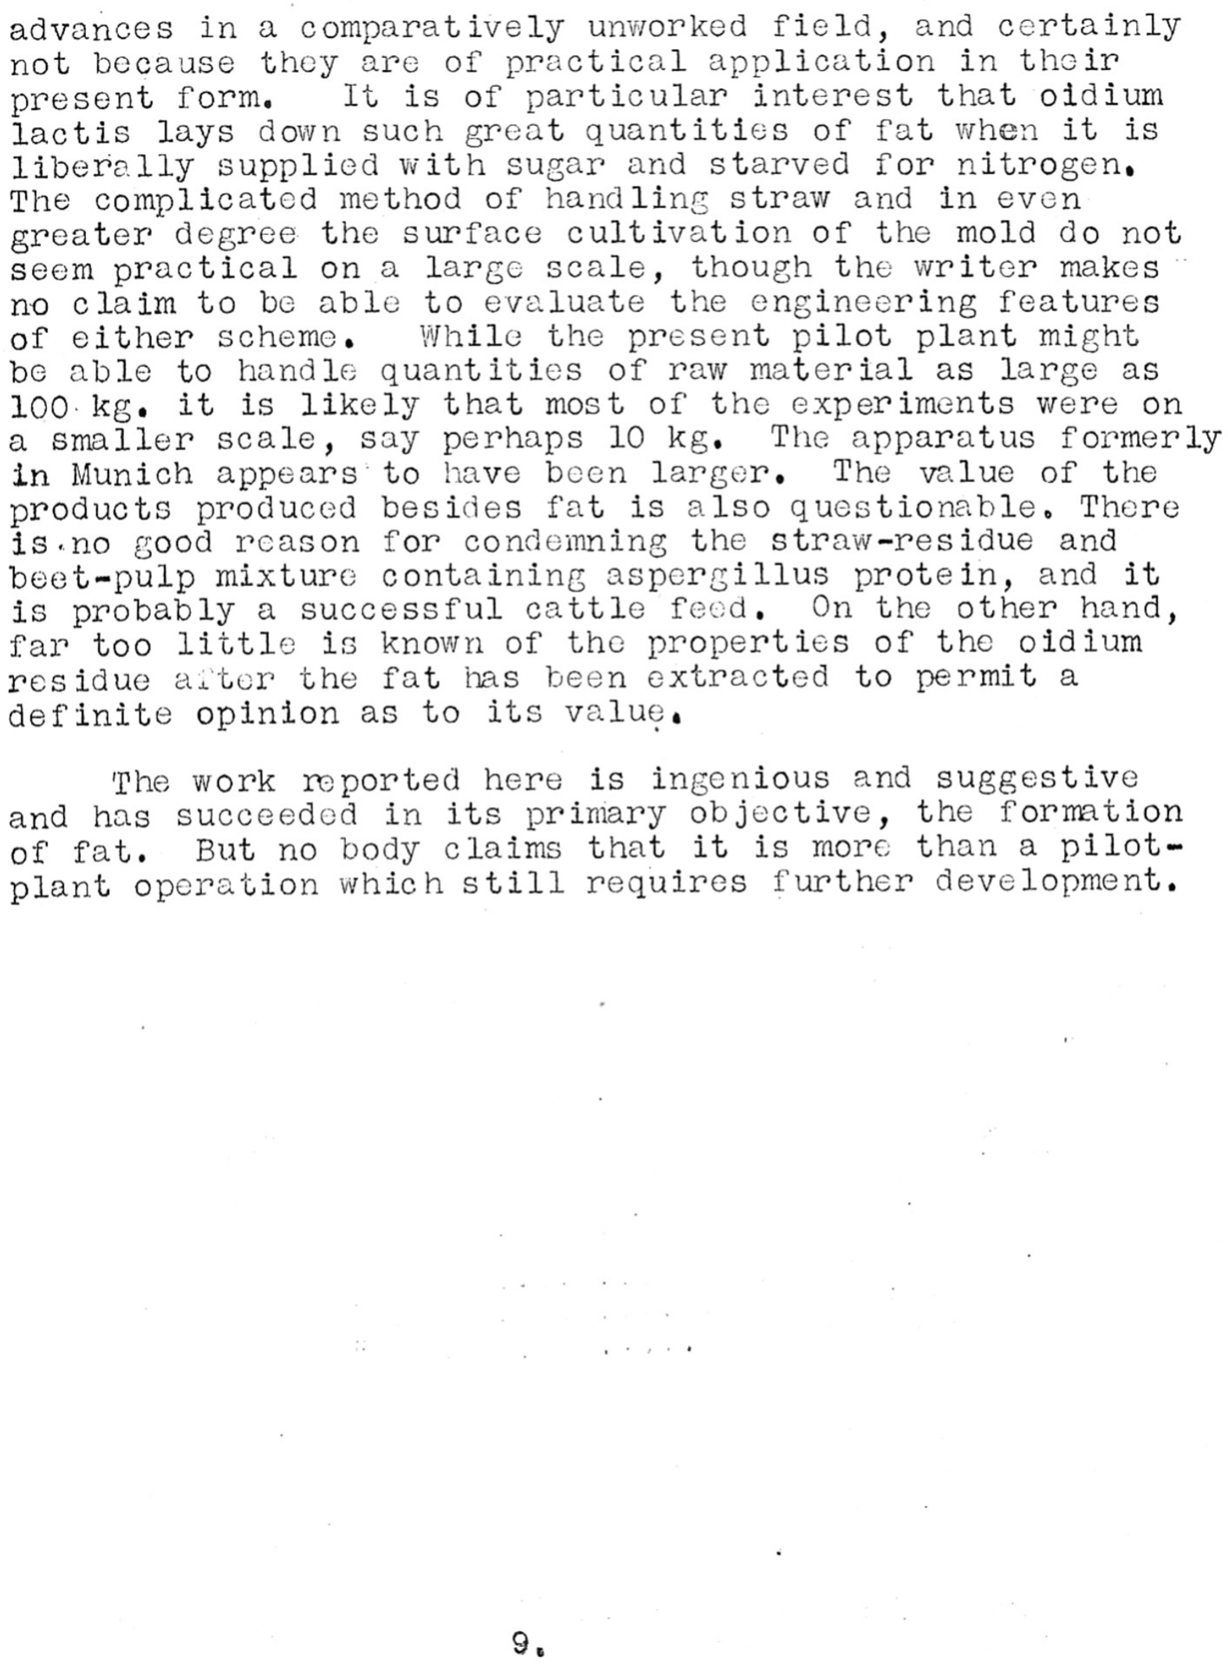
Fat laid down on the medium made from straw or oat hulls is different from that made with the whey medium. The former is semi solid, firm, very pale yellow, and with a slight "oily" odor. The latter is a viscous liquid, yellow brown, and smells slightly of milk. These fats are triglycerides. Prof. Eleier, at the Institute für Nagrungsmittel in Munich, made analysis of the fat made from straw and sawdust, with the following results:

Saturated acids.........	45 percent
Oleic acid.............	41 "
Oxy acids	2 "

The remainder is mostly linoleic and linolic acids. The claim was made that about 5.5 kg of fat could be obtained from 100 kg of straw. It was stated that this fat has been used without any ill effects in human diets containing no other fats.

In conclusion, the foregoing schemes have been described in considerable detail because they appear to embody

Figure A.97: Production of fat by *Oidium lactis* [FIAT 371].

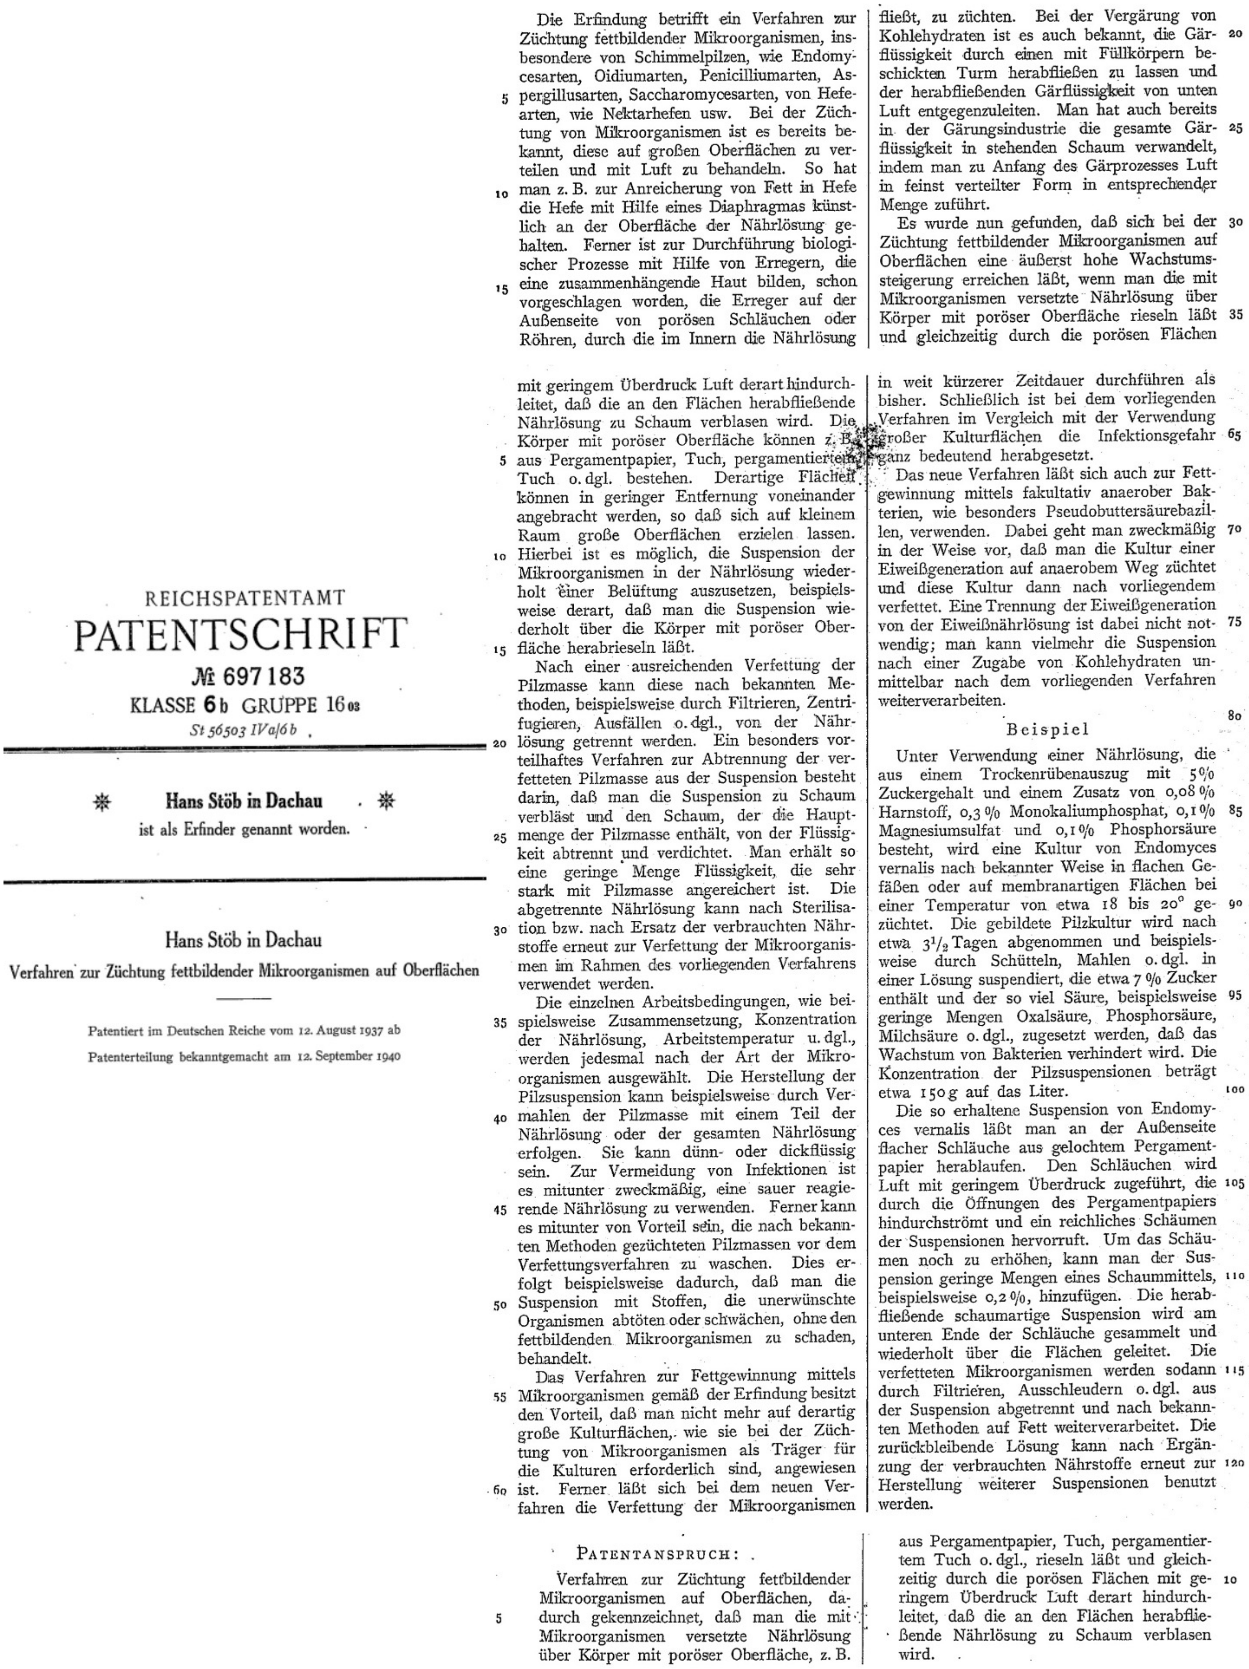


advances in a comparatively unworked field, and certainly not because they are of practical application in their present form. It is of particular interest that oidium lactis lays down such great quantities of fat when it is liberally supplied with sugar and starved for nitrogen. The complicated method of handling straw and in even greater degree the surface cultivation of the mold do not seem practical on a large scale, though the writer makes no claim to be able to evaluate the engineering features of either scheme. While the present pilot plant might be able to handle quantities of raw material as large as 100 kg. it is likely that most of the experiments were on a smaller scale, say perhaps 10 kg. The apparatus formerly in Munich appears to have been larger. The value of the products produced besides fat is also questionable. There is no good reason for condemning the straw-residue and beet-pulp mixture containing aspergillus protein, and it is probably a successful cattle feed. On the other hand, far too little is known of the properties of the oidium residue after the fat has been extracted to permit a definite opinion as to its value.

The work reported here is ingenious and suggestive and has succeeded in its primary objective, the formation of fat. But no body claims that it is more than a pilot-plant operation which still requires further development.

9.

Figure A.98: Production of fat by *Oidium lactis* [FIAT 371].



REICHSPATENTAMT
PATENTSCHRIFT
№ 697 183
KLASSE 6b GRUPPE 16_{03}
St 56503 IVa/6b

Hans Stöb in Dachau
ist als Erfinder genannt worden.

Hans Stöb in Dachau
Verfahren zur Züchtung fettbildender Mikroorganismen auf Oberflächen

Patentiert im Deutschen Reiche vom 12. August 1937 ab
Patenterteilung bekanntgemacht am 12. September 1940

Die Erfindung betrifft ein Verfahren zur Züchtung fettbildender Mikroorganismen, insbesondere von Schimmelpilzen, wie Endomycesarten, Oidiumarten, Penicilliumarten, Aspergillusarten, Saccharomycesarten, von Hefearten, wie Nektarhefen usw. Bei der Züchtung von Mikroorganismen ist es bereits bekannt, diese auf großen Oberflächen zu verteilen und mit Luft zu behandeln. So hat man z. B. zur Anreicherung von Fett in Hefe die Hefe mit Hilfe eines Diaphragmas künstlich an der Oberfläche der Nährlösung gehalten. Ferner ist zur Durchführung biologischer Prozesse mit Hilfe von Erregern, die eine zusammenhängende Haut bilden, schon vorgeschlagen worden, die Erreger auf der Außenseite von porösen Schläuchen oder Röhren, durch die im Innern die Nährlösung fließt, zu züchten. Bei der Vergärung von Kohlehydraten ist es auch bekannt, die Gärflüssigkeit durch einen mit Füllkörpern beschickten Turm herabfließen zu lassen und der herabfließenden Gärflüssigkeit von unten Luft entgegenzuleiten. Man hat auch bereits in der Gärungsindustrie die gesamte Gärflüssigkeit in stehenden Schaum verwandelt, indem man zu Anfang des Gärprozesses Luft in feinst verteilter Form in entsprechender Menge zuführt.

Es wurde nun gefunden, daß sich bei der Züchtung fettbildender Mikroorganismen auf Oberflächen eine äußerst hohe Wachstumssteigerung erreichen läßt, wenn man die mit Mikroorganismen versetzte Nährlösung über Körper mit poröser Oberfläche rieseln läßt und gleichzeitig durch die porösen Flächen mit geringem Überdruck Luft derart hindurchleitet, daß die an den Flächen herabfließende Nährlösung zu Schaum verblasen wird. Die Körper mit poröser Oberfläche können z. B. aus Pergamentpapier, Tuch, pergamentiertem Tuch o. dgl. bestehen. Derartige Flächen können in geringer Entfernung voneinander angebracht werden, so daß sich auf kleinem Raum große Oberflächen erzielen lassen. Hierbei ist es möglich, die Suspension der Mikroorganismen in der Nährlösung wiederholt einer Belüftung auszusetzen, beispielsweise derart, daß man die Suspension wiederholt über die Körper mit poröser Oberfläche herabrieseln läßt.

Nach einer ausreichenden Verfettung der Pilzmasse kann diese nach bekannten Methoden, beispielsweise durch Filtrieren, Zentrifugieren, Ausfällen o. dgl., von der Nährlösung getrennt werden. Ein besonders vorteilhaftes Verfahren zur Abtrennung der verfetteten Pilzmasse aus der Suspension besteht darin, daß man die Suspension zu Schaum verbläst und den Schaum, der die Hauptmenge der Pilzmasse enthält, von der Flüssigkeit abtrennt und verdichtet. Man erhält so eine geringe Menge Flüssigkeit, die sehr stark mit Pilzmasse angereichert ist. Die abgetrennte Nährlösung kann nach Sterilisation bzw. nach Ersatz der verbrauchten Nährstoffe erneut zur Verfettung der Mikroorganismen im Rahmen des vorliegenden Verfahrens verwendet werden.

Die einzelnen Arbeitsbedingungen, wie beispielsweise Zusammensetzung, Konzentration der Nährlösung, Arbeitstemperatur u. dgl., werden jedesmal nach der Art der Mikroorganismen ausgewählt. Die Herstellung der Pilzsuspension kann beispielsweise durch Vermahlen der Pilzmasse mit einem Teil der Nährlösung oder der gesamten Nährlösung erfolgen. Sie kann dünn- oder dickflüssig sein. Zur Vermeidung von Infektionen ist es mitunter zweckmäßig, eine sauer reagierende Nährlösung zu verwenden. Ferner kann es mitunter von Vorteil sein, die nach bekannten Methoden gezüchteten Pilzmassen vor dem Verfettungsverfahren zu waschen. Dies erfolgt beispielsweise dadurch, daß man die Suspension mit Stoffen, die unerwünschte Organismen abtöten oder schwächen, ohne den fettbildenden Mikroorganismen zu schaden, behandelt.

Das Verfahren zur Fettgewinnung mittels Mikroorganismen gemäß der Erfindung besitzt den Vorteil, daß man nicht mehr auf derartig große Kulturflächen, wie sie bei der Züchtung von Mikroorganismen als Träger für die Kulturen erforderlich sind, angewiesen ist. Ferner läßt sich bei dem neuen Verfahren die Verfettung der Mikroorganismen in weit kürzerer Zeitdauer durchführen als bisher. Schließlich ist bei dem vorliegenden Verfahren im Vergleich mit der Verwendung großer Kulturflächen die Infektionsgefahr ganz bedeutend herabgesetzt.

Das neue Verfahren läßt sich auch zur Fettgewinnung mittels fakultativ anaerober Bakterien, wie besonders Pseudobuttersäurebazillen, verwenden. Dabei geht man zweckmäßig in der Weise vor, daß man die Kultur einer Eiweißgeneration auf anaerobem Weg züchtet und diese Kultur dann nach vorliegendem verfettet. Eine Trennung der Eiweißgeneration von der Eiweißnährlösung ist dabei nicht notwendig; man kann vielmehr die Suspension nach einer Zugabe von Kohlehydraten unmittelbar nach dem vorliegenden Verfahren weiterverarbeiten.

Beispiel

Unter Verwendung einer Nährlösung, die aus einem Trockenrübenauszug mit 5% Zuckergehalt und einem Zusatz von 0,08% Harnstoff, 0,3% Monokaliumphosphat, 0,1% Magnesiumsulfat und 0,1% Phosphorsäure besteht, wird eine Kultur von Endomyces vernalis nach bekannter Weise in flachen Gefäßen oder auf membranartigen Flächen bei einer Temperatur von etwa 18 bis 20° gezüchtet. Die gebildete Pilzkultur wird nach etwa $3^1/_2$ Tagen abgenommen und beispielsweise durch Schütteln, Mahlen o. dgl. in einer Lösung suspendiert, die etwa 7% Zucker enthält und der so viel Säure, beispielsweise geringe Mengen Oxalsäure, Phosphorsäure, Milchsäure o. dgl., zugesetzt werden, daß das Wachstum von Bakterien verhindert wird. Die Konzentration der Pilzsuspensionen beträgt etwa 150 g auf das Liter.

Die so erhaltene Suspension von Endomyces vernalis läßt man an der Außenseite flacher Schläuche aus gelochtem Pergamentpapier herablaufen. Den Schläuchen wird Luft mit geringem Überdruck zugeführt, die durch die Öffnungen des Pergamentpapiers hindurchströmt und ein reichliches Schäumen der Suspensionen hervorruft. Um das Schäumen noch zu erhöhen, kann man der Suspension geringe Mengen eines Schaummittels, beispielsweise 0,2%, hinzufügen. Die herabfließende schaumartige Suspension wird am unteren Ende der Schläuche gesammelt und wiederholt über die Flächen geleitet. Die verfetteten Mikroorganismen werden sodann durch Filtrieren, Ausschleudern o. dgl. aus der Suspension abgetrennt und nach bekannten Methoden auf Fett weiterverarbeitet. Die zurückbleibende Lösung kann nach Ergänzung der verbrauchten Nährstoffe erneut zur Herstellung weiterer Suspensionen benutzt werden.

Patentanspruch:

Verfahren zur Züchtung fettbildender Mikroorganismen auf Oberflächen, dadurch gekennzeichnet, daß man die mit Mikroorganismen versetzte Nährlösung über Körper mit poröser Oberfläche, z. B. aus Pergamentpapier, Tuch, pergamentiertem Tuch o. dgl., rieseln läßt und gleichzeitig durch die porösen Flächen mit geringem Überdruck Luft derart hindurchleitet, daß die an den Flächen herabfließende Nährlösung zu Schaum verblasen wird.

Vorrichtung zum Züchten fettbildender Mikroorganismen, insbesondere Fetthefen

Patentiert im Deutschen Reiche vom 29. Oktober 1937 ab

Patenterteilung bekanntgemacht am 11. Juli 1940

Zur Züchtung und Anregung der Fettbildung von hautbildenden Mikroorganismen, beispielsweise von Hefe und Schimmelpilzen, wie Endomyces vernalis, Oidium, Aspergillus-, Saccharomycesarten u. dgl., hat man ursprünglich eine Nährlösung mit den betreffenden Mikroorganismen geimpft. Nach einem ausreichenden Wachstum hat man die so gewonnene Kultur entfernt und dieses Verfahren unter Verwendung einer neuen Nährlösung wiederholt. Es hat sich jedoch im Laufe der Zeit als zweckmäßig herausgestellt, die Nährlösung von der Pilzschicht durch ein Diaphragma zu trennen. Zu diesem Zweck hat man durchlässige Membranflächen, beispielsweise Pergamentpapier, enggewebte Tücher, Papier u. dgl., auf einer Seite mit den jeweiligen Mikroorganismen geimpft und auf der anderen Seite mit einer entsprechenden Nährlösung bespült, die durch die Membranflächen hindurchdiffundierte und so ein Wachstum der Pilzschicht ermöglichte. Die Züchtung und Verfettung von Mikroorganismen auf diese Art ist jedoch mit gewissen Schwierigkeiten verbunden, da eine ausreichende Luftzufuhr, insbesondere von der mit der Nährlösung bespülten Seite her, schwer möglich ist. Neben einer ausreichenden Nährstoffversorgung ist aber gerade eine genügende Belüftung der Pilzschicht ausschlaggebend für deren Wachstum und insbesondere für deren Fettbildung.

Ferner ist es bereits bekannt, als Fermentträger Gipsblöcke oder feste Blöcke aus Schamotte zu verwenden. Es wurde nun gefunden, daß man bei der Züchtung von fettbildenden Mikroorganismen, insbesondere Fetthefen, neben der Nährstoffzufuhr zugleich eine ausreichende Belüftung erzielen kann, wenn man eine Vorrichtung verwendet, die aus einem oder mehreren schwach geneigten porösen Flächengebilden aus biegsamer Unterlage und halbstarrem Überzug und einer für die Zufuhr der Nährlösung auf die obere oder untere Seite der Flächen geeigneten Zerstäubungsvorrichtung besteht. Hierbei wird die Struktur und die Porosität der Flächengebilde so gewählt, daß bei der wechselnden Zufuhr von Luft und Nährlösung die Luft auch durch die Flächengebilde hindurch an die Pilzschicht gelangt. Die mit der Nährlösung gefüllten Poren übernehmen dabei die Versorgung der Pilzdecke mit den erforderlichen Nährstoffen und die mit Luft gefüllten Poren die Versorgung mit Luft. Die Verwendung derartiger Flächengebilde ermöglicht die gleichzeitige Zuführung von Nährstoffen und Sauerstoff, wodurch ein erhöhtes Wachstum und eine starke Fettbildung der Mikroorganismen erzielt wird.

Die porösen Flächengebilde aus biegsamer Unterlage können beispielsweise aus grobmaschigem Tuch oder aus Drahtgewebe bestehen. Der halbstarre Überzug wird zweckmäßigerweise aus Ton, Gips, porösem Stein, porösen Kunstmassen oder aus auf mechanischem Wege porös gemachten Stoffen gebildet. Besonders geeignet sind Flächengebilde, welche durch Aufstreichen von erhärtenden Massen, wie z. B. Gipsbrei, auf ein grobmaschiges Tuch oder auf Drahtgewebe hergestellt sind. Dabei kann es zweckmäßig sein, der Gipsmasse oder ähnlichen Stoffen faserige oder körnige Zusatzstoffe, wie beispielsweise Sägespäne, Holzschliff, Cellulose, Holzkohle, gebrannte Kieselgurkörper oder andere indifferente, körnige Stoffe, zuzusetzen, welche die Porosität der Gipsfläche noch wesentlich erhöhen. Auch kann man der Gipsmasse Stoffe beisetzen, welche die Festigkeit erhöhen oder die Biegsamkeit beeinflussen, so z. B. Schmelzen aus Boraten und Magnesiumverbindungen, quellbare organische Stoffe, Wasserglas u. dgl. Um ein rasches Entleeren und Füllen der Poren zu erzielen, ist unter Umständen eine Imprägnierung der gesamten Flächen mit Stoffen, die eine rasche Abgabe der Flüssigkeit bewirken oder wasserabstoßend sind, angebracht. Derartige Imprägniermittel, wie z. B. geringe Mengen von Schwermetallseifen, kann man entweder der Grundmasse selbst oder den Zusatzstoffen, wie Holzmehl, Cellulose u. dgl., zusetzen. Flächengebilde der vorstehend beschriebenen Art, welche als Träger für die Pilzkulturen dienen, sind im Gegensatz zu den bisher verwendeten Membranflächen aus Tuch und Papier fest und in sich porös. Sie besitzen eine große Widerstandsfähigkeit gegen chemische oder mechanische Angriffe und gewährleisten daher einen einwandfreien Betrieb während der Züchtung und Verfettung der Pilzkulturen. Beulen oder Falten können bei diesen Flächengebilden nicht auftreten, so daß die Herzucht und die Ernte der Pilzkultur sowie eine gleichmäßige Verteilung der Nährlösung auf der gesamten Fläche ohne Schwierigkeiten durchführbar sind. Ein weiterer Vorteil bei der Verwendung der neuen Kulturflächen besteht darin, daß man bei ihnen von starren Unterlagen, wie Blechen usw., unabhängig ist. Sie sind ferner ausreichend griffig, so daß das Saatgut genügend haftenbleibt und Störungen im Laufe der Züchtung vermieden werden. Der Hauptvorteil der neuen Flächengebilde besteht darin, daß sie durch und durch porös sind und daß man darauf angesetzte Pilzkulturen nicht nur ausreichend mit Nährstoffen versehen, sondern gleichzeitig von beiden Seiten intensiv belüften kann. Gerade dadurch wird ein ausreichendes Wachstum der Kultur und eine weitgehende Verfettung erst möglich. Da die neuen Kulturflächen in sich einheitlich sind, ist es gleichgültig, auf welcher Seite man die Pilzkulturen züchtet. Die Nährlösung wird dabei stets auf der der Pilzkultur entgegengesetzten Seite aufgebracht. Für eine möglichst gleichmäßige Verteilung der Nährlösung ist es zweckmäßig, die von ihr berieselte Seite der Flächen mit Rillen, Kanälen o. dgl. zu versehen oder die Flächen durch kleine Dämme in einzelne Felder aufzuteilen. Um die mit der Nährlösung berieselte Seite vor einer vorzeitigen Abnutzung zu schützen, ist es zweckmäßig, sie mit einer widerstandsfähigen Schutzschicht, z. B. aus Hartpech o. dgl., zu überziehen, die ihrerseits, um den Eintritt der Nährlösung in die Poren zu ermöglichen, mit zahlreichen Öffnungen versehen sein muß. Die Kulturflächen können verschiedene Formen, z. B. die von ebenen Flächen oder von Röhren, haben. Besonders vorteilhaft ist jedoch die Verwendung von flächenförmigen Unterlagen, die senkrecht, waagerecht oder geneigt angebracht sein können. Es wurde gefunden, daß die Verwendung von zur waagerechten Richtung schwach geneigten Flächen besonders empfehlenswert ist.

Beim Züchten von Mikroorganismen unter Verwendung der beschriebenen Flächengebilde wird nach einer Sterilisation der gesamten Anlage die eine Seite der Flächen mit den betreffenden Mikroorganismen dadurch geimpft, daß man diese durch Zerstäuben oder Aufsprühen aufbringt. Auf die andere Seite wird sodann stetig oder mit Unterbrechungen die für das Wachstum oder die Verfettung der Mikroorganismen erforderliche Nährlösung gebracht, wobei gleichzeitig auch genügend Luft durch die Poren hindurchgeblasen wird. Die einzelnen Arbeitsbedingungen, wie z. B. Zusammensetzung, Konzentration und Zuflußgeschwindigkeit der Nährlösung sowie Temperatur u. dgl., werden in jedem Fall nach der Art der Mikroorganismen ausgewählt. Die zur Verwendung gelangenden Nährlösungen können wiederholt zum Besprühen der Kulturfläche benutzt werden, nachdem sie gegebenenfalls vorher gereinigt und sterilisiert oder verbrauchte Stoffe ergänzt wurden. Der gesamte Arbeitsgang kann bei normalem, erhöhtem oder auch vermindertem Druck stattfinden. Sind Wachstum und Fettbildung der Mikroorganismen bis zu dem gewünschten Maße vollendet, so wird die auf den Flächen haftende Haut in geeigneter Weise abgenommen. Vor einer erneuten Impfung der porösen Flächen ist es zweckmäßig, diese beispielsweise mit Hitze, Dampf oder Formaldehyd zu sterilisieren.

In der Zeichnung ist eine beispielsweise Ausführungsform einer Vorrichtung gemäß der Erfindung schematisch im Schnitt dargestellt. In dieser Zeichnung bedeutet *A* einen viereckigen Kasten, in dessen rechter und linker Hälfte je sechs zur waagerechten Richtung schwach geneigte poröse Flächengebilde derart angebracht sind, daß die Flächengebilde fortschreitend nach unten der Mitte des Kastens mehr angenähert und von den Seitenwänden weiter entfernt sind. Die Flächen *B* sind auf der Oberseite mit Rillen versehen und werden auf dieser Seite durch die von einer mittleren Hauptleitung *H* traubenartig abgezweigten Düsen *D* mit Nährlösung berieselt. Auf der Unterseite der Flächengebilde *B* befindet sich die Pilzschicht *C*. Die aus den Düsen *D* auf die Flächen *B* aufgesprühte Nährlösung rieselt über die schwach geneigten Flächen und läuft schließlich in die Sammelkästen *E* ab, aus denen sie wiederholt den Düsen *D* zugeführt werden kann. An der Bodenfläche des Kastens befindet sich eine Vorrichtung *F* für die Zufuhr von Luft, die an der Deckfläche durch *G* austreten kann.

Es ist nicht unbedingt erforderlich, daß in der beschriebenen Anordnung die Berieselung der Flächen auf der Oberseite stattfindet und die Pilzkultur auf der Unterseite der porösen Flächen gezüchtet wird; man kann genau so gut die Flächengebilde von der Unterseite her berieseln, während sich die Pilzkultur auf der Oberseite befindet. Ferner ist man bei der Berieselung der Flächen mit Nährlösung nicht unbedingt auf fest angebrachte Düsen angewiesen, man kann z. B. auch bewegliche Sprühvorrichtungen verwenden, welche die gesamte Fläche bestreichen.

PATENTANSPRÜCHE:

1. Vorrichtung zum Züchten fettbildender Mikroorganismen, insbesondere Fetthefen, bestehend aus einem oder mehreren schwach geneigten porösen Flächengebilden aus biegsamer Unterlage und halbstarrem Überzug und einer für die Zufuhr der Nährlösung auf die obere oder untere Seite der Flächen geeigneten Zerstäubungsvorrichtung.

2. Vorrichtung nach Anspruch 1, dadurch gekennzeichnet, daß die vorzugsweise mit Rillen, Kanälen o. dgl. versehenen oder durch kleine Dämme in einzelne Felder aufgeteilten porösen Flächengebilde aus einer Gipsmasse zweckmäßig mit einem Zusatz körniger oder faseriger Stoffe, z. B. Sägemehl, Holzschliff, Cellulose o. dgl., bestehen und auf einer biegsamen Unterlage aufgebracht sind.

Kulturverfahren für Mikroorganismen auf einer durch einen flächenförmigen Träger gestützten Zwischenschicht

Patentiert im Deutschen Reich vom 9. August 1940 an
Patenterteilung bekanntgemacht am 13. August 1942

Die Erfindung betrifft ein Kulturverfahren für Mikroorganismen, wie Endomyces-, Hefe-, Monilia-, Oospora-, Aspergillus- und andere Pilzarten. Es ist bekannt, solche Züchtungen in flachen Schalen, auf Flächen aus porösen oder durchlässigen Stoffen oder auf undurchlässigen Membranen durchzuführen. Das Schalenverfahren kommt für den Großbetrieb nicht in Betracht, da es zu umständlich und zu teuer ist. Bei dem bisher durchgeführten Oberflächenverfahren mit senkrecht oder schräg stehenden Flächen läuft oft ein großer Teil der Saat nutzlos ab, oder das Wachstum der Pilze ist schlecht, da die Trägerbeschaffenheit weder für den Halt der Saat noch für die Versorgung der Kultur mit Nährlösung tauglich war. Besonders trifft dies für die bereits vorgeschlagenen, zur Dialyse geeigneten Membranen zu, die ein Durchwandern der Flüssigkeit und ein Wandern derselben in der Membran selbst nicht zulassen, so daß ein befriedigendes Wachstum der Kultur ausgeschlossen ist. Um ein gutes Haften der Saat und eine gute Versorgung mit Nährlösung zu erreichen, wird das Kulturverfahren erfindungsgemäß in der Weise durchgeführt, daß die Kultur auf einer die Flüssigkeitsbewegung in sich und durch sich zulassenden Zwischenschicht aus organischen Stoffen in Faserform gezüchtet wird, die in senkrechter oder geneigter Lage die zugeführte Nährlösung in sich aufnimmt und weitergibt.

Für die Durchführung des Verfahrens sind folgende Gesichtspunkte maßgebend:

Als Träger für die Zwischenschicht und der darauf gezüchteten Pilzdecke kommen alle Arten von flächigen Körpern aus flüssigkeitsdurchlässigem oder undurchlässigem Stoff in Betracht. Der Träger kann aus Blech, welches durchlocht oder nicht durchlocht ist, aus Asphalt- oder Bitumenpappe, aus porösen Massen, wie Gips oder keramischen Stoffen, aus Faser- oder Drahtgeweben usw. bestehen. Die Faserplatten, die sich besonders bewähren, können auch gedichtet sein, so daß ihre Porosität aufgehoben ist, was durch Anstrich oder Überzug mit Bitumen, Kunstharz usw. zu erreichen ist. Die Lagenanordnung der Träger kann geneigt oder senkrecht stehend sein. Auf der so zur Verfügung stehenden Tragfläche wird eine dünne Schicht aus organischen Stoffen in Faserform, z. B. in Holz-, Stroh-, Zell-, Papierstoff, auch Pülpe ist geeignet, erzeugt. Deren Schicht wird vorzugsweise durch Aufspritzen oder Aufschleudern der wäßrigen Fasermassesuspension hergestellt. Hierzu ist in der Regel eine geeignete Vorbehandlung der Fasermasse, wie Mahlung u. dgl., notwendig. Besonders eignet sich aufgeschlossenes Stroh, das in bekannter Weise mit Dampf von höherem Druck oder mit Alkalien bzw. alkalisch wirkenden Stoffen behandelt worden ist. Die Verwendung einer aufgeschlossenen Strohmasse hat vor allem den Vorteil der Billigkeit und der Ergiebigkeit und weiterhin, den Vorzug, daß die aufgeschlossenen Strohteile unter Umständen als Nährmittel in der gewonnenen Pilzmasse verbleiben können. Auch können zur Herstellung der Fasermasse jüngere Teile von Laubbäumen, die auf mechanischem Wege, gegebenenfalls unter Zusatz von zucker- oder stärkehaltigen Stoffen u. dgl., als Futtermittel aufbereitet worden sind, verwendet werden. Die Faserstoffsuspension, die knotenfrei sein muß, wird z. B. durch Düsen oder durch Bürstenwalzen auf die Tragfläche ausgeblasen oder aufgeschleudert. Die Konzentration der Suspension wird so gehalten, daß möglichst geringe Ablaufverluste entstehen. Werden Träger aus porösem Stoff verwendet, so ist es zweckmäßig, durch Vorbehandlung des Trägers mit heißem Wasser oder Dampf und nachheriges Abtropfenlassen seine Saugfähigkeit zu steigern, so daß ein großer Teil der Feuchtigkeit der aufgebrachten Fasermassesuspension in die Poren des Trägers eingesaugt wird und die Fasermasse einen dünen, gleichmäßigen und zusammenhängenden Belag mit guter Haftung bildet, der auch gegebenenfalls durch ablaufende Flüssigkeiten nicht zerstört wird.

Statt in Suspension kann die Zwischenschichtmasse auch in trockenem Zustand auf den Träger aufgebracht werden, wobei zweckmäßig gleichzeitig Flüssigkeit aufgespritzt wird. Um die Haftfähigkeit des Belags auf dem Träger zu erhöhen, kann der Trägeroberfläche eine besondere Gestaltung gegeben werden, z. B. durch Anbringen von Holzstiften, von kleinen Körpern aus Bimsstein, aus Koks, keramischen Körpern u. dgl. Auf der Zwischenschicht wird die Pilzdecke aufgesät. Die Nährlösung kann entweder der Zwischenschicht unmittelbar auf der Kulturseite des Trägers oder durch den porösen Träger hindurch zugeführt werden.

Nach beendetem Wachstum der Pilzdecke kann diese mit Wasser mit oder ohne Zusätzen gewaschen werden. Die Abnahme der Pilzdecke kann durch Abspülen oder Abblasen erfolgen, wobei sie zusammen mit der Zwischenschicht abgelöst wird. Je nach der weiteren Verwendungsart der Pilzernte können die Faserteile der Zwischenschicht als Nähr- oder Futterstoffe in der abgenommenen Masse verbleiben oder z. B. durch Aufschwemmen oder Aussieben oder Auswaschen aus ihr abgeschieden werden. Die ausgeschiedene faserige Masse kann unter Umständen mehrmals zur Faserschichtbildung verwendet werden. Vor Wiederverwendung des Trägers wird in der Regel eine Keimfreimachung notwendig sein, die je nach den Verhältnissen mit chemischen Mitteln, wie verdünntem Chlorwasser oder durch Wärmeeinrichtung oder beiden durchgeführt werden kann, wobei bei porösen Trägern die Wärmeeinwirkung zur Beeinflussung der Porosität, wie erwähnt, ausgenutzt werden kann. Das Verfahren kann sowohl zur Fett- und Eiweißsynthese als auch zur Gewinnung organischer Säuren und anderer Produkte unter Beachtung der jeweiligen Bedingungen verwendet werden.

PATENTANSPRÜCHE:

1. Kulturverfahren für Mikroorganismen auf einer durch einen flächenförmigen Träger gestützten Zwischenschicht, dadurch gekennzeichnet, daß die Kultur auf einer die Flüssigkeitsbewegung in sich und durch sich zulassenden Zwischenschicht aus organischen Stoffen in Faserform gezüchtet wird, die in senkrechter oder geneigter Lage die zugeführte Nährlösung in sich aufnimmt und weitergibt.

2. Verfahren nach Anspruch 1, dadurch gekennzeichnet, daß die Zwischenschichtmasse in Suspension auf den Träger aufgebracht wird.

3. Verfahren nach Anspruch 1, dadurch gekennzeichnet, daß die Zwischenschichtmasse in trockenem Zustand unter gleichzeitiger Aufspritzung von Flüssigkeit auf dem Träger verteilt wird.

4. Verfahren nach Ansprüchen 1 bis 3, dadurch gekennzeichnet, daß die Zwischenschicht auf einem Träger aus porösem Stoff erzeugt wird.

5. Verfahren nach Anspruch 4, dadurch gekennzeichnet, daß der poröse Träger vor Aufbringen der Zwischenschicht durch Behandlung mit heißer Flüssigkeit, Dampf o.dgl. und Abtropfenlassen in den Zustand erhöhter Saugfähigkeit versetzt wird.

6. Verfahren nach Ansprüchen 1 bis 5, dadurch gekennzeichnet, daß die Zwischenschichtmasse aus als Futtermittel dienendem Stoff besteht, der gegebenenfalls in der fertigen und abgelösten Kulturdecke verbleibt.

7. Verfahren nach Anspruch 6, dadurch gekennzeichnet, daß die Zwischenschichtmasse aus sogenanntem Kochstroh besteht, das aus Stroh durch Behandlung mit alkalischen Stoffen mit oder ohne erhöhter Temperatur oder durch Behandlung mit Dampf bei erhöhtem Druck gewonnen wird.

8. Verfahren nach Ansprüchen 1 bis 6, dadurch gekennzeichnet, daß als Zwischenschichtmasse Holz, insbesondere jüngere Teile von Laubbäumen verwendet werden, die auf mechanischem Wege, gegebenenfalls unter Zusatz von zucker- oder stärkehaltigen Stoffen u. dgl., als Futtermittel aufbereitet worden sind.

Hans Stöb in Dachau

Kulturträger zur Züchtung von flächenbildenden Mikroorganismen

Patentiert im Deutschen Reich vom 9. August 1940 an

Patenterteilung bekanntgemacht am 13. August 1942

Die Erfindung betrifft einen Kulturträger zur Züchtung flächenbildender Mikroorganismen, wie Endomyces-, Hefe-, Monilia-, Oospora-, Aspergillus- und andere Pilzarten. Man hat bisher schon solche Kulturen in flachen Schalen oder nach dem Lichtungsverfahren gezüchtet. Beide Maßnahmen eignen sich nicht für den Großbetrieb. Auch ist für die Züchtung solcher Kulturen schon das Oberflächenverfahren vorgeschlagen worden, bei welchem die Kulturen auf flächenförmigen Trägern wachsen sollen. Als Träger sind poröse Flächengebilde mit biegsamer Unterlage aus grobmaschigem Tuch oder Drahtgewebe und halbstarrem Überzug aus Ton, Gips oder sonstigen porösen Stoffen mit irgendwelchen Zusätzen zur Erhöhung der Porosität verwendet worden. Die Versorgung der Pilzdecke mit Nährlösung findet dabei durch den halbstarren porösen Überzug statt. Da die Porosität des genannten Überzugs der Unterlage für die Ernährung der Kultur zu unzuverlässig ist, geht die Erfindung andere Wege und versorgt die Kultur durch die Vereinigung besonderer Vorkehrungen und Anordnungen längs der Oberfläche des Trägers, verläßt sich also nicht auf das Hindurchwandern der Nährlösung durch die Träger. Zu diesem Zweck bestehen erfindungsgemäß die Träger aus Platten, z. B. aus Faserplatten nach Art der Bau- und Isolierplatten, die auf der Kulturseite bekannte Oberflächenformungen, wie Rippen, Rillen, aufweisen, geeignet zur Führung der der Kulturseite zugeführten Nährflüssigkeit und zum Halt einer aufzubringenden Faserzwischenschicht und der Pilzdecke.

In der Zeichnung ist ein Ausführungsbeispiel der Erfindung wiedergegeben.

Fig. 1 zeigt eine Einheit des Kulturträgers von der Seite gesehen;

Fig. 2 zeigt die Einheit von vorn gesehen;

Fig. 3 zeigt die Ansicht einer kammartigen Hilfsvorrichtung.

Die Einheit der Vorrichtung besteht aus einer flächenförmigen Platte 1, die als Träger der Kulturen anzusprechen ist. Dieser Träger wird senkrecht oder gegen die Senkrechte nur wenig geneigt angeordnet, z. B. aufgehängt,

wie in der Zeichnung gezeigt ist. Er besteht z. B. aus Faserstoff, sog. Faserplatten, die an sich porös sind und auch imprägniert sein können, z. B. mit Bitumen, wodurch die Festigkeitseigenschaften verbessert werden, ohne daß die Porosität besonders leidet. Anderseits kann der Träger auch mit solchen Stoffen imprägniert sein, die eine teilweise oder völlige Dichtung ergeben. Der Träger ist oben zwischen zwei Leisten 2 und 3 befestigt, deren Spalt 4 sich nach oben konisch erweitert. Mit diesen Leisten 2 und 3 hängt der Träger an Tragleisten 5 und 6. Auf seinen beiden Breitseiten ist der Träger 1 mit von oben nach unten verlaufenden Nuten oder Rillen 7 versehen. Auf die so gestalteten Breitseiten des Trägers wird vorzugsweise eine dünne Zwischenschicht aus Faserstoff, z. B. aufgeschlossener Strohmasse, aufgebracht, der die Grundlage für die Kultur darstellt und mit dem Saatgut versehen wird. Der in Fig. 3 dargestellte Kamm 8 ist ein Hilfsmittel für die Aufbringung der Faserzwischenschicht. Seine drahtförmigen Zinken 9, die im Abstand der Rillen 7 stehen, werden dabei in die Rillen 7 eingelegt und wandern mit dem Fortschreiten der Faserdecke, um zu verhüten, daß die Rillen verstopft werden. Insbesondere ist ein Verstopfen unter den Leisten 2 und 3 zu vermeiden, wo der Einlauf der Nährlösung stattfindet. Zur Zuführung der Nährlösung dient vorzugsweise eine gleichmäßig fortlaufend oder unterbrochen beschickte Ausflußvorrichtung, die langsam längs des Spaltes 4 wandert. Die Nährflüssigkeit füllt diesen Spalt, in welchem zur Verteilung oder Speicherung Saugstoffe eingebracht sein können, und läuft dem Träger 1 entlang, vor allem in den Rillen 7, nach unten und verteilt sich so auf die beiderseitigen Kulturflächen. Zur Ernte der Pilzdecke wird diese gegebenenfalls mit der Faserzwischenschicht von dem Träger 1 abgezogen, wozu der Kamm 8 vorteilhaft verwendet werden kann. Die Gesamtanlage besteht aus einer Reihe solcher Trägereinheiten, die nebeneinander an den Leisten 5 und 6 hängen.

Statt die Kulturträger mit Leisten 2 und 3 aufzuhängen, kann man auch Aufhängeglieder verwenden, die zwischen zwei mit ihrer Rückseite aneinanderliegenden Trägern befestigt sind. Dabei können die Träger an den aneinanderliegenden Rückflächen ganz oder teilweise mit irgendeiner Masse, wie Bitumen, Asphalt, Kunstharz u. dgl., behandelt sein, die die beispielsweise aus Metall bestehenden Aufhängeglieder schützend umhüllt oder selbst eine andere Aufhängemöglichkeit ergibt und den Zusammenhalt der Platten sichert.

Die Zuführung der Nährlösung auf der Kulturseite bringt eine einfache Gestaltung und damit billige Herstellung der Träger mit sich, ermöglicht eine leichte Reinigung der Träger und gestattet deshalb auch die Verwendung von Nährlösungen, die Verunreinigungen suspendiert enthalten oder die während des Betriebes Ausfüllungen bilden. Auch ist es bei geeigneter Anordnung der Oberflächenformungen möglich, mit sehr geringem Diffusionswiderstand zu arbeiten, wodurch die Ausnutzung auch von Lösungen mit sehr geringem Gehalt an nutzbaren Stoffen, z. B. von Sulfitschlempen, möglich ist.

Die Vorrichtung kann auch zur biologischen Gewinnung von organischen Säuren und ähnlichen biologischen Verfahren verwendet werden.

PATENTANSPRÜCHE:

1. Kulturträger zur Züchtung von flächenbildenden Mikroorganismen, dadurch gekennzeichnet, daß die Träger (1) aus Platten, z. B. Faserplatten nach Art der Bau- und Isolierplatten, bestehen, die auf der Kulturseite bekannte Oberflächenformungen, wie Rippen, Rillen, aufweisen, geeignet zur Führung der der Kulturseite zugeführten Nährflüssigkeit und zum Halt einer aufzubringenden Faserzwischenschicht und der Pilzdecke.

2. Vorrichtung nach Anspruch 1, dadurch gekennzeichnet, daß die Träger (1) schmale, beiderseits längs gerillte Einheiten bilden, die einzeln zwischen Tragleisten (2, 3) gefaßt sind, deren Spalt (4) sich nach oben als Auffangrinne für die Nährlösung erweitert.

3. Vorrichtung nach Anspruch 1 und 2, dadurch gekennzeichnet, daß der Träger (1) aus zwei untrennbar verbundenen Teilen besteht und Aufhängeglieder, die durch die Verbindungsmasse geschützt sind, enthält.

4. Vorrichtung nach Anspruch 1 bis 3, gekennzeichnet durch eine Zuführungsvorrichtung für die Nährlösung, deren Ausflußöffnung über die obere Kante der Träger hin und her beweglich angeordnet ist.

5. Vorrichtung zur Bedienung des Kulturträgers, gekennzeichnet durch einen mit seinen Zinken (9) in die Rillen (7) des Trägers (1) passenden Kamm (8) zum Verlegen der Rillen (7) beim Aufbringen der Faserzwischenschicht und zur Abnahme der Pilzdecke gegebenenfalls gemeinsam mit der Zwischenschicht.

Hans Stöb in Dachau

Kulturträger zur Züchtung von flächenbildenden Mikroorganismen, insbesondere für die biologische Fett- und Eiweißgewinnung

Patentiert im Deutschen Reich vom 9. August 1940 an

Patenterteilung bekanntgemacht am 13. August 1942

Die Erfindung betrifft einen flächenförmigen Träger zur Kultur von Mikroorganismen, besonders deckenbildenden Pilzen für die biologische Fett- und Eiweißgewinnung. Man hat die Kultur dieser Pilze bisher auf Flüssigkeiten oder gestaltlosen Massen, wie Sägespänen, Torf, Stroh u. dgl., in Schalen vorgenommen, was aber umständlich und unwirtschaftlich ist. Auch wurden schon flächenförmige Träger für die Kulturen vorgeschlagen, und zwar aus Gips, keramischen Stoffen, Papier und Geweben, auf deren einen Seite die Pilzdecke aufgesät und auf deren anderen Seite die Nährflüssigkeit zugeführt wird. Das Züchtungsverfahren mit solchen Trägern ist unergiebig und teuer. Die Herstellung geeigneter Gipsflächen ist fast unmöglich, ihre Porosität ist für die erstrebten Zwecke zu gering und die Zerbrechlichkeit ist zu groß. Auch Papier, Pergamentpapier und Gewebe ergeben ein schlechtes Wachstum und eine ungleichmäßige Verteilung der Nährflüssigkeit, so daß auch hiermit ein zweckentsprechender Dauerbetrieb nicht durchzuführen ist. Die Erfindung erstrebt einen Kulturträger, der in Einheiten unterteilt in großer Zahl in Englage angeordnet, z. B. aufgehängt werden kann, eine gute fortlaufende Versorgung der Pilzdecke mit Nährflüssigkeit zuläßt und eine leichte Abnahme der fertigen Pilzdecke ermöglicht. Erfindungsgemäß ist dies dadurch erreicht, daß die Kulturträger aus Platten gebildet sind, die einheitlich aus Faserstoff nach Art der Bau- und Isolierplatten bestehen und die, gegebenenfalls nach verstärkender Imprägnierung, senkrecht angeordnet, z. B. aufgehängt werden.

Die vorzugsweise ebenen Platten bestehen aus Holz-, Stroh- oder Torffasermassen, genau wie die sogenannten Bauplatten, Dämm-Isolierplatten, wie z. B. die Kapag-Linoleumunterlage, usw. Diese Massen in Plattenform sind für die erstrebten Zwecke nicht nur hinsichtlich ihrer Festigkeit und ihrer Durchlässigkeit für Flüssigkeiten besonders vorteilhaft, sondern eignen sich auch deshalb sehr gut, weil sie das Saatgut und die entstehende Pilzdecke genügend festzuhalten vermögen, die fertige Pilzdecke leicht abblasen oder abspülen lassen, korrosionsbeständig sind und leicht keimfrei gemacht werden können. Die Faserstoffplatten können in unimprägniertem Zustand Verwendung finden. Es hat sich aber gezeigt, daß die mechanische Festigkeit durch geeignete Imprägnierung gesteigert werden kann, wozu Bitumen, Asphalt und ähnliche Stoffe verwendet werden können. Die diesen Stoffen innewohnenden wasserabweisenden Eigenschaften sind im allgemeinen nicht störend und können für den Anfang, wo sie besonders in Erscheinung treten, durch Netzmittel behoben werden. Die Naßfestigkeit der so imprägnierten Platten und ihre allgemeine Widerstandsfähigkeit ist aber erheblich größer als diejenige der nichtimprägnierten Platten. Man kann auch die Fasern der Platten mit Wasserglas o. dgl. tränken und durch Behandlung mit Säuren oder geeigneten Salzen die Kieselsäure als Gallerte ausfällen und so die Poren ganz oder teilweise ausfüllen.

Die Platten werden mittels Stiften u. dgl. an Leisten, Bändern, Drähten befestigt und an Tragschienen aufgehängt. Dies ergibt an den Lochstellen eine erhöhte Beanspruchung der Platten, weshalb die Festigkeit an diesen Stellen zweckmäßig durch besondere Imprägnierung gesteigert wird. Zwei in unmittelbarer Nachbarschaft hängende Platten werden zweckmäßig gemeinsam an den gegenseitig zugekehrten Flächen mit Nährflüssigkeit versorgt, die dann durch die Platten zu den Pilzdecken hindurchwandert. Zur Lenkung der Nährflüssigkeit und zur gleichmäßigen Verteilung derselben können die von der Flüssigkeit bespülten Seiten der Platten durch Formänderungen der Oberfläche, wie Rippen oder Rillen, oder durch Auftragungen in Felder, schmale Streifen oder Bahnen unterteilt werden.

Eine besonders günstige Kombination zweier Nachbarplatten ist als Ausführungsbeispiel in der Zeichnung wiedergegeben. Hier sind die beiden Faserplatten 1 und 2 mit ganz geringem Spalt 3 aneinandergelegt und mit Leisten 4 an Tragleisten 5, 6 aufgehängt, die einen Spalt 7 zwischen sich lassen, der sich beispielsweise konisch nach oben erweitert und die Fortsetzung des Plattenspaltes 3 bildet. Die Platten 1 und 2 sind vorzugsweise durch Stifte 8, die auf ihre Fläche verteilt sind, miteinander verbunden. Sie ragen aus der Oberfläche der Platten hervor, sind entweder aus Holz oder aus in der Längsrichtung elastischem Stoff hergestellt oder mit elastischen Köpfen versehen, so daß sie eine Ausdehnung der Platten ermöglichen und ihnen eine Art Atmung gestatten. Am äußeren Umfang und unten ist der Spalt 3 durch irgendwelche Einlagen usw. abgedichtet, so daß die in den Spalt 7 eingefüllte Nährflüssigkeit durch die Platten hindurchwandert. Die gleiche Anordnung kann getroffen werden, wenn die Gegenplatte aus einem anderen Stoff, z. B. aus Blech besteht. Die Zufuhr der Nährflüssigkeit in den Spalt 7 und dadurch in den Spalt 3 geschieht zweckmäßig durch ein Zuführungsrohr oder einen Trichter, welche Zuführungsteile hin und her beweglich angeordnet sind. Die Flüssigkeit staut sich im Spalt 3 der Platten und beeinflußt den Feuchtigkeitszustand der Flächen, wovon die Diffusion zu den Kulturflächen abhängt. Besonders vorteilhaft ist es, die Flüssigkeit mit Unterbrechungen zuzuführen. Durch die Zufuhr der Lösung mit Überstaudruck füllen sich die Poren mit Flüssigkeit, und es zeigt sich deutlich ein Anschwellen der Flächen; hört die Zufuhr auf, so tritt Saugwirkung der abströmenden Flüssigkeit ein und die Schwellung verwandelt sich in eine Zusammenziehung, so daß in den Poren ein Wechsel im Flüssigkeitsgehalt erzielt wird. Große Poren in den Platten sind beim Arbeiten mit Überstau und Überdruck und mit unterbrochener Zufuhr der Nährlösung nicht erwünscht, da dabei ein Durchströmen der Flüssigkeit und eine Verletzung der Pilzdecke eintreten können. Durch rhythmische Unterbrechung der Flüssigkeitszufuhr kann eine pulsierende Strömung im Spalt 7 erreicht werden. Die Spaltweite wird im allgemeinen 0,5 mm nicht überschreiten. Haben z. B. die Kulturplatten eine Stärke von je 6 mm, also insgesamt 12 mm, so genügt eine elastische Formänderung von etwa 4 %, um diese Spaltweite zu erreichen. Diese geringfügige Formänderung ist für Faserplatten unbedenklich beliebig oft durchzuführen. Durch den Überdruck auf Grund des Überstaus ist eine dauernd gleichmäßige Verteilung der Nährflüssigkeit und damit ein gleichmäßiges Wachstum, hohe Flächen- und Materialausbeute bei verringerter Infektionsgefahr zu erzielen. Es hat sich gezeigt, daß die Flächenausbeute unter Umständen mehrfach höher wird als bei Einrichtungen, die ohne Überdruck arbeiten. Die Menge der Nährflüssigkeit, der nötige Druck, der Rhythmus der Zufuhr richten sich nach der Art der Organismen, dem Vegetationszustand, der Stärke der Lösung, der Größe der Platten usw. Die Keimfreimachung der Flächen, die Aufbringung des Saatgutes, das Abnehmen der fertigen Pilzdecke vollziehen sich auf bekannte Weise. Die Nährflüssigkeit kann gegebenenfalls unter entsprechender Ergänzung mehrmals verwendet werden.

PATENTANSPRÜCHE:

1. Kulturträger zur Züchtung von flächenbildenden Mikroorganismen, insbesondere für die biologische Fett- und Eiweißgewinnung, gekennzeichnet durch einheitlich aus Faserstoff bestehende Platten nach Art der Bau- und Isolierplatten, die, gegebenenfalls nach verstärkender Imprägnierung, senkrecht angeordnet, z. B. aufgehängt werden.

2. Kulturträger nach Anspruch 1, dadurch gekennzeichnet, daß die Faserstoffplatten an ihrer Oberfläche in bekannter Weise durch Formänderungen oder Auftragungen in schmale Streifen oder Bahnen unterteilt werden.

3. Kulturträger nach Anspruch 1 und 2, dadurch gekennzeichnet, daß durch Parallelanordnung einer zweiten Platte ein Spalt zur Aufnahme der Nährflüssigkeit gebildet wird, wobei die zu einer Einheit vereinigten beiden Platten (1, 2) zur Beeinflussung des Druckes im Plattenspalt elastisch miteinander zusammenhängen können.

Kulturanlage für mikrobiologische Prozesse

Patentiert im Deutschen Reich vom 6. Mai 1941 an
Patenterteilung bekanntgemacht am 1. Oktober 1942

Die Erfindung betrifft eine Kulturanlage für mikrobiologische Prozesse, wie z. B. für die biologische Fettsynthese. Hierzu sind bereits senkrecht oder geneigt angeordnete Flächen vorgeschlagen worden, denen die Nährflüssigkeit für die von ihnen getragenen Kulturen zugeführt wird. Die notwendigen Flächen sind verhältnismäßig sehr groß. Für die Versorgung der Kulturen mit Nährflüssigkeit und dadurch für das Gedeihen dieser Kulturen ist es von wesentlicher Bedeutung, in welcher Weise es gelingt, die Träger der Kulturen als verteilende Vermittler der Nährflüssigkeit auszunutzen. Als solche Flächen wurden schon Gipsflächen, Gewebeflächen, Tonflächen, zur Dialyse geeignete Membranen, wie Pergamentpapier, präpariertes Filtrierpapier usw., vorgeschlagen. Alle diese Träger haben wesentliche Nachteile und sind der Förderung der Kulturen nicht dienlich. Die einen dieser Träger sind zu wenig flüssigkeitsdurchlässig, so daß die Versorgung der Kulturen leidet, während die anderen, wie die Gewebe, zu durchlässig sind, so daß die Kulturen weggeschwemmt werden und nicht gedeihen können. Wieder andere sind zu wenig fest oder behalten zu wenig ihre glatte flächenförmige Form, um als versorgende Unterlage für die Kulturen brauchbar zu sein. Diese Nachteile liegen bei der eine Kombination darstellenden Kulturanlage gemäß der Erfindung nicht vor, da die erwähnten ungünstigen Eigenschaften, wie mangelnde Durchlässigkeit oder übermäßige Durchlässigkeit und ungenügende Formbeständigkeit durch die Kombination beseitigt sind. Dies ist erreicht durch die Vereinigung eines flächenförmigen Stützkörpers mit flüssigkeitsdurchlässigen gesonderten Tragflächen und einem flüssigkeitsaufnehmenden Polster in der Form, daß die flüssigkeitsdurchlässigen Tragflächen zwischen dem die Nährflüssigkeit führenden Stützkörper und den die Kultur tragenden Polstern sitzen und diesen die Nährflüssigkeit vermitteln.

In der Zeichnung ist ein Ausführungsbeispiel der Erfindung wiedergegeben.

Die Kulturanlage besteht aus einer Vielzahl von vorzugsweise hängenden Einheiten, die wie folgt aufgebaut sind: Den Kern jeder Einheit bildet ein Stützkörper 1, der flächenförmig ist und beispielsweise aus Hartfaserplatten, Bitumenpappe, Blech o. dgl. besteht. Auf jeder Seite dieses Stützkörpers 1 liegt eine Tragfläche 2 auf, in der Weise, daß ein Spalt zwischen ihr und dem Stützkörper 1 verbleibt, in den durch eine trichterförmige Anordnung 3 die Nährflüssigkeit eingeführt werden kann. Diese Tragflächen sind flüssigkeitsdurchlässig, und zwar in reichlichem Maße, jedoch ohne eine Schwemmwirkung auszuüben. Sie bestehen beispielsweise aus besonderen, teilweise gedichteten Geweben, wie aus Ce-Pe-Faser, aus flüssigkeitsundurchlässigen Folien, wie Pergamentpapier, asphaltierten oder paraffinierten Papier, die zur Erreichung der Durchlässigkeit für die Nährlösung mit einer Vielzahl kleiner Löcher versehen sind. Auf die Außenseite dieser Träger 2 ist ein Polster 4 aus einer Faser- oder Körnerschicht aufgebracht, auf welcher die Saat verteilt wird und welche die Nährflüssigkeit aufnimmt und an diese weitergibt. Die Durchlässigkeit der Trägerflächen 2 wird so gewählt bzw. gestaltet, daß sie weder für die Versorgung der Kultur zu gering ist noch zu stark, so daß ein Abschwemmen des Polsters samt der Kultur eintreten würde. Um die Oberflächenbeschaffenheit der Tragflächen ständig gleich glatt und gleichmäßig zu erhalten und Änderungen im Betrieb zu vermeiden, sind die Tragflächen 2 mit dem Stützkörper 1 punkt- oder streifenförmig verbunden, was durch kaltes oder heißes Verkleben, z. B. durch Anbügeln oder sonstwie geschehen kann. Dadurch wird der Spalt zwischen dem Stützkörper 1 und den Tragflächen 2 streifenförmig unterbrochen, wobei die Unterteilungen 5 in der Strömungsrichtung der Nährflüssigkeit also von oben nach unten verlaufen. Je nach Beschaffenheit und Neigung zur Faltenbildung werden die Tragflächen entweder trocken oder in befeuchtetem Zustand auf den Stützkörper 1 aufgebracht. Soweit bei feuchten Tragflächen das stellenweise Verkleben mit dem Stützkörper nicht möglich ist, müssen diese zu diesem Zweck stellenweise mit Hilfe erhitzter Rollen, Bügeleisen usw. getrocknet werden. Die Zufuhr der Nährlösung kann in gleichmäßigem Strom oder pulsierend erfolgen. Die stoßweise Versorgung hat bei den gelochten Tragflächen besondere Vorteile. Während des Versorgungsstoßes dringt die Flüssigkeit durch die Tragflächen 2 in das Faserpolster 4 und wird von diesem aufgenommen und an die Kultur weitergegeben. Während der Stoßpause strömt die überschüssige Lösung wieder in den Spalt zwischen Stützkörper 1 und Tragfläche 2 zurück, so daß die Gefahr der Überschwemmung der Kulturschicht und des sie tragenden Polsters 4 vermieden bleibt. Das Faserpolster 4 hält die Kultur fest und versorgt sie gleichmäßig mit Nährflüssigkeit. Sie bildet eine Zwischenschicht zwischen Kultur und Tragfläche, die die Ablösung der Kulturen erleichtert. Die Ablösung und Verarbeitung von Faserpolster und Kultur erfolgt gleichzeitig und gemeinsam.

PATENTANSPRÜCHE:

1. Kulturanlage für mikrobiologische Prozesse, wie z. B. biologische Fettgewinnung aus senkrecht oder geneigt angeordneten Flächen, gekennzeichnet durch die Vereinigung eines flächenförmigen Stützkörpers (1) mit flüssigkeitsdurchlässigen gesonderten Tragflächen (2) und einem flüssigkeitsaufnehmenden Polster (4) in der Form, daß die flüssigkeitsdurchlässigen Tragflächen (2) zwischen dem die Nährflüssigkeit führenden Stützkörper (1) und den die Kultur tragenden Polstern (4) sitzen.

2. Kulturanlage nach Anspruch 1, dadurch gekennzeichnet, daß im Spalt zwischen dem Stützkörper (1) und den Tragflächen (2) in der Strömungsrichtung der Nährflüssigkeit verlaufende streifenförmige Unterbrechungen (5) vorgesehen sind, die durch stellenweise Verklebungen oder sonstige Verbindungen des Trägers (2) mit dem Stützkörper (1) gebildet sind.

3. Kulturanlage nach Anspruch 1 und 2, dadurch gekennzeichnet, daß die Tragfläche (2) zwischen Stützkörper (1) und Polster (4) beispielsweise aus mit einer Vielzahl kleiner Öffnungen versehenem Pergamentpapier besteht und das Polster (4) aus einer flüssigkeitsaufnehmenden faserigen oder körnigen Schicht gebildet wird.

4. Arbeitsweise bei der Kulturanlage nach Anspruch 1 bis 3, dadurch gekennzeichnet, daß die zwischen Stützkörper (1) und Tragfläche (2) erfolgende Nährlösungszufuhr intermittierend ist und vorzugsweise durch eine Wanderdüse erfolgt.

FIAT 545. ***Pulling Wool by the Use of Enzymes.***

PURPOSE

To remove wool from pelts without detriment to the wool fibers nor to the hides.

SUMMARY

By the use of an enzymatic product called Arazym NSL, the above purpose appears to have been accomplished with excellent results.

ARAZYM NSL

This process of pulling wool from sheep skins was developed by the Röhm and Haas Company of Darmstadt who are the manufacturers of the enzyme product named Arazym NSL.

The process was explained by Dr. C. T. Kaulter, Technical Director of Röhm and Haas and is a development of research carried on during the past five or six years.

Manufacture

Originally the enzyme used was produced from animal pancreas imported frozen from American packing houses. When the war interrupted these importations, they began producing enzymes from cultures in bran. Protease is the active principle. Production has been terminated at present due to the destruction of the factory, but it is now being reconstructed and they expect to be in production again by spring.

The mould, Aspergil paraciticus, is produced in pure strains in the laboratory. Trays of bran seeded with the mould are cultured for five days at 20^oC. to 22^oC. The temperature must not be allowed to rise above 28^oC. Temperature is kept down by cold water which is circulated through the shelves on which the shallow trays of bran rest.

No particular attention is paid to pH control but it normally runs around 6.8.

The mould culture is then extracted with water and precipitated with ammonium sulphate or sodium sulphate or a mixture of both. It also may be precipitated with ethyl alcohol. The salts used for precipitation are in 35% solution.

After the proteinic matter is precipitated out, it is put through a filter press and then dried under vacuum at 30^oC. A protease of high concentration which contains 40,000 enzymatic units is thus obtained. [...]

COMPARISONS BETWEEN OLD AND NEW PULLING PROCESSES

The old lime process took only about 12 hours instead of 24 hours and could be used on cold skins. Also the old methods with lime and sulfide were very cheap.

However, the resulting pulled wool by the enzyme process is much superior in handle and contains no bothersome chemicals. The additional cost of the enzyme over the cheaper chemicals is more than made up in the increased value and higher selling price of the wool as well as an estimated increase in wool yield of approximately 10%.

FIAT 570. ***Inoculation of Food Plant Seeds with Specific Strains of Microorganisms.***

FIAT 871. ***The Luminometer.***

ABSTRACT

A new visual photometer, called the Luminometer, was developed in 1943 by Carl Zeiss to measure very faint brightnesses. In contrast to ordinary photometers it has a field of view of 30^o and an exit pupil 9 mm. in diameter. The measuring range covered by the Luminometer is 10^{-2} to 10^{-6} millilambert. At a brightness of 10^{-5} millilambert, for instance, the average error of matching brightnesses in one operation is about 15 percent. The accuracy as compared with that of ordinary photometers is about three times greater. [...]

FIAT 910. ***Production of Pharmaceutical and Industrial Enzymes in Southern Germany.***

ABSTRACT

In this report the processing methods are described for the manufacture of a number of enzymes.

Protease. The protein digestive enzyme was produced from special strains of Aspergillus parasiticus for use, in varying proportions, in commercial preparations for the leather industry.

Pectinase was produced from Aspergillus wentii for use in the fruit industries in clearing juices, prevention of jellying, etc.

Pancreatic amylase, called "Degomma", was prepared before the war from beef pancreas and used in the textile trade for destarching.

"Clauden" a styptic substance from beef lung tissue was a popular item for the pharmaceutical trade for the control of hemorrhage.

Sanarthrit a cartilaginous extract was used pharmaceutically as an anti-arthritic injectable substance (non proteinaceous).

"Telatuten" another injectable substance was on the pharmaceutical market for the treatment of arteriosclerosis.

"Luizyme" an enzyme mixture was a mixture of cellulases, amylases, proteases and esterases obtained from Aspergillus uryceae and widely used in the treatment of digestive disorders.

The preparation of these enzymatic substances is recorded in detail. [...]

Evaluation:

Manufacturing processes of enzymes for pharmaceutical and industrial operation have been obtained. Many of these agents are comparatively new, all of them are valuable assets in this particular field of chemistry. The source of some of them is unique and the whole field warrants the attention of the American industry.

ENZYMATIC PRODUCTS OF RÖHM AND HAAS, DARMSTADT

General

Röhm and Haas at Darmstadt originally went into the enzyme field with the assumption of developing a pharmaceutical market. After some initial pharmaceutical enzyme production, it was discovered that the scope of protease application in the industrial field was much greater, and further production gradually turned entirely towards this field.

For the production of protease, special strains of Aspergillus parasiticus were utilized. Wheat bran substances served as a medium. The filtrates of autolyzed cultures contain the active principles which can be precipitated with ammonium sulphate. The precipitates are dried and serve in standardized solutions or powder mixes of varying percentages as the active agents in commercial preparations. Some of these are sold under the trade names of Burnus, Oropon and Arazym.

THE PRODUCTION OF PROTEASE

Fundamentally the production of protease consists of five steps:

Pure culture of Aspergillus parasiticus.

Production of initial spore yield for protease.

Production of technical spore seed for protease.

Volume culture of Aspergillus parasiticus and processing to liquid enzyme concentrates.

Production of dry protease, (enzyme-carrier) mixture and storage. [...]

[This report describes and shows large, advanced, industrial biotechnology installations for producing and purifying a variety of different enzymes. Please see pp. 2450–2452 for some of the illustrations from this report.]

FIAT 964. ***Regarding the Resistance to Temperature Variations of Zygotes of Chlamydomonas.***

ABSTRACT

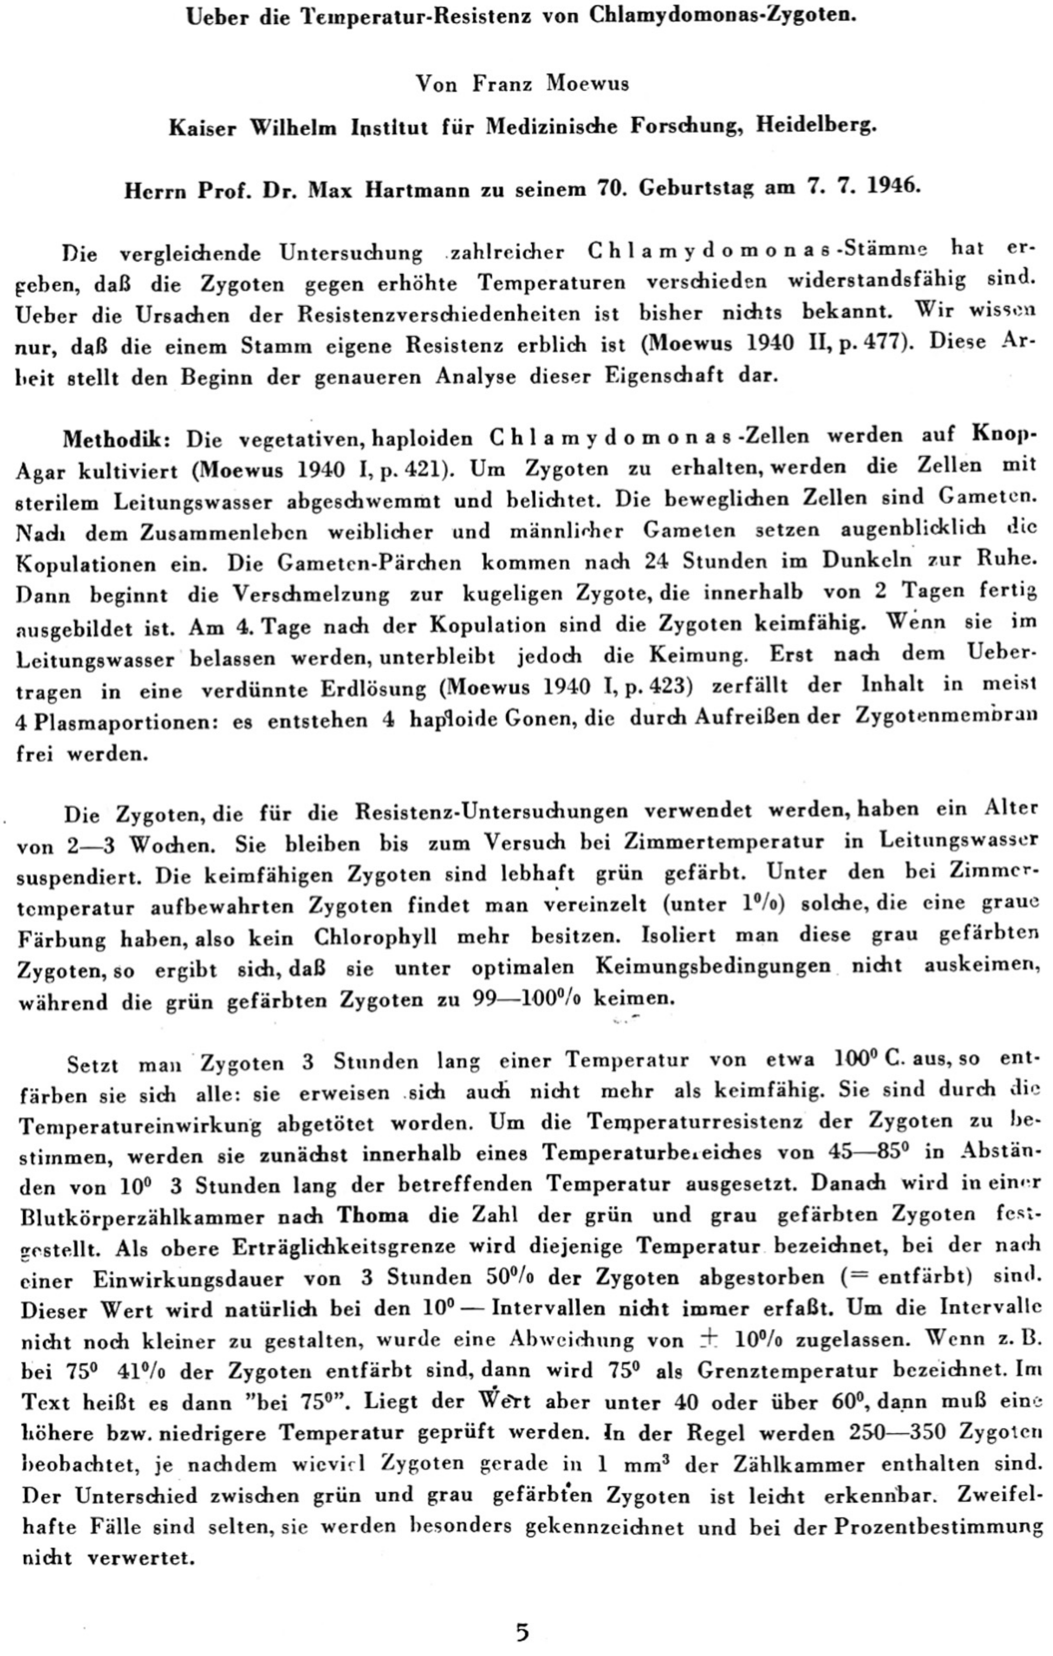
Complete details of the technique used in experimenting with the zygotes are given. Two strains of Chlamydomonas eugametos were tested at temperatures varying from 45–85^{o}C. Resistance paralleled the osmotic properties of the zygotes, the cells with greater osmotic properties being more resistant. Two genes condition the zygote resistance. The gene "zyte" rules the osmotic valves while the gene "zyme" modifies the strength of the osmotic membranes of the zygotes.

BIOGRAPHICAL NOTE

Dr. Franz Moewus, professorial lecturer for botany at Heidelberg University, is a pupil of Dr. Max Hartmann with whom he worked in the Kaiser Wilhelm Institute for Biology in Berlin-Dahlem. For the past 10 years he has been engaged at the Kaiser Wilhelm Institute for Medical Research in Heidelberg on research in the field of fertility agents, sex determining substances, blastocholines, and genetic investigations.

[This report covers culture methods and genetic analysis of *Chlamydomonas* algae to engineer robust microorganisms for biotechnology applications. Since *Chlamydomonas* is photosynthetic, it was probably being studied for applications such as photosynthetic biofuel or food production.

See pp. 2454–2460 for some of the pages from this report.]



Ueber die Temperatur-Resistenz von Chlamydomonas-Zygoten.

Von Franz Moewus

Kaiser Wilhelm Institut für Medizinische Forschung, Heidelberg.

Herrn Prof. Dr. Max Hartmann zu seinem 70. Geburtstag am 7. 7. 1946.

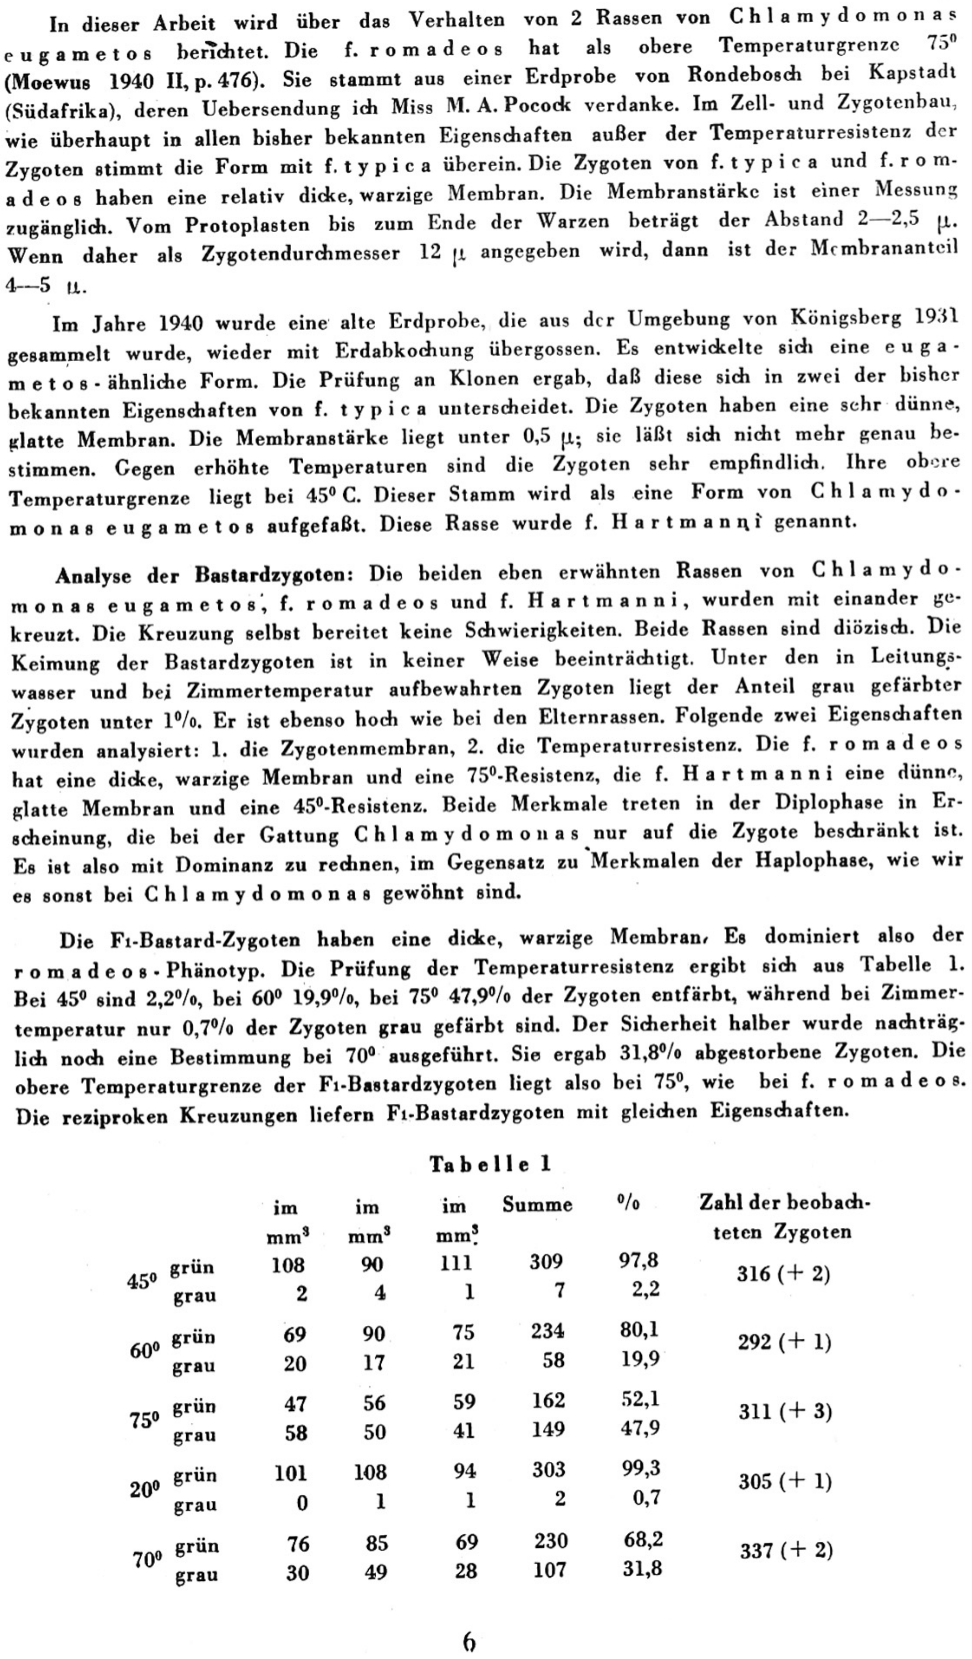
Die vergleichende Untersuchung zahlreicher Chlamydomonas-Stämme hat ergeben, daß die Zygoten gegen erhöhte Temperaturen verschieden widerstandsfähig sind. Ueber die Ursachen der Resistenzverschiedenheiten ist bisher nichts bekannt. Wir wissen nur, daß die einem Stamm eigene Resistenz erblich ist (**Moewus** 1940 II, p. 477). Diese Arbeit stellt den Beginn der genaueren Analyse dieser Eigenschaft dar.

Methodik: Die vegetativen, haploiden Chlamydomonas-Zellen werden auf **Knop**-Agar kultiviert (**Moewus** 1940 I, p. 421). Um Zygoten zu erhalten, werden die Zellen mit sterilem Leitungswasser abgeschwemmt und belichtet. Die beweglichen Zellen sind Gameten. Nach dem Zusammenleben weiblicher und männlicher Gameten setzen augenblicklich die Kopulationen ein. Die Gameten-Pärchen kommen nach 24 Stunden im Dunkeln zur Ruhe. Dann beginnt die Verschmelzung zur kugeligen Zygote, die innerhalb von 2 Tagen fertig ausgebildet ist. Am 4. Tage nach der Kopulation sind die Zygoten keimfähig. Wenn sie im Leitungswasser belassen werden, unterbleibt jedoch die Keimung. Erst nach dem Uebertragen in eine verdünnte Erdlösung (**Moewus** 1940 I, p. 423) zerfällt der Inhalt in meist 4 Plasmaportionen: es entstehen 4 haploide Gonen, die durch Aufreißen der Zygotenmembran frei werden.

Die Zygoten, die für die Resistenz-Untersuchungen verwendet werden, haben ein Alter von 2—3 Wochen. Sie bleiben bis zum Versuch bei Zimmertemperatur in Leitungswasser suspendiert. Die keimfähigen Zygoten sind lebhaft grün gefärbt. Unter den bei Zimmertemperatur aufbewahrten Zygoten findet man vereinzelt (unter 1%) solche, die eine graue Färbung haben, also kein Chlorophyll mehr besitzen. Isoliert man diese grau gefärbten Zygoten, so ergibt sich, daß sie unter optimalen Keimungsbedingungen nicht auskeimen, während die grün gefärbten Zygoten zu 99—100% keimen.

Setzt man Zygoten 3 Stunden lang einer Temperatur von etwa 100° C. aus, so entfärben sie sich alle: sie erweisen sich auch nicht mehr als keimfähig. Sie sind durch die Temperatureinwirkung abgetötet worden. Um die Temperaturresistenz der Zygoten zu bestimmen, werden sie zunächst innerhalb eines Temperaturbereiches von 45—85° in Abständen von 10° 3 Stunden lang der betreffenden Temperatur ausgesetzt. Danach wird in einer Blutkörperzählkammer nach **Thoma** die Zahl der grün und grau gefärbten Zygoten festgestellt. Als obere Erträglichkeitsgrenze wird diejenige Temperatur bezeichnet, bei der nach einer Einwirkungsdauer von 3 Stunden 50% der Zygoten abgestorben (= entfärbt) sind. Dieser Wert wird natürlich bei den 10° — Intervallen nicht immer erfaßt. Um die Intervalle nicht noch kleiner zu gestalten, wurde eine Abweichung von ± 10% zugelassen. Wenn z. B. bei 75° 41% der Zygoten entfärbt sind, dann wird 75° als Grenztemperatur bezeichnet. Im Text heißt es dann "bei 75°". Liegt der Wert aber unter 40 oder über 60%, dann muß eine höhere bzw. niedrigere Temperatur geprüft werden. In der Regel werden 250—350 Zygoten beobachtet, je nachdem wieviel Zygoten gerade in 1 mm³ der Zählkammer enthalten sind. Der Unterschied zwischen grün und grau gefärbten Zygoten ist leicht erkennbar. Zweifelhafte Fälle sind selten, sie werden besonders gekennzeichnet und bei der Prozentbestimmung nicht verwertet.

Figure A.109: Culture methods and genetic analysis of *Chlamydomonas* algae to engineer robust microorganisms for biotechnology applications [FIAT 964].



In dieser Arbeit wird über das Verhalten von 2 Rassen von Chlamydomonas eugametos berichtet. Die f. romadeos hat als obere Temperaturgrenze 75° (Moewus 1940 II, p. 476). Sie stammt aus einer Erdprobe von Rondebosch bei Kapstadt (Südafrika), deren Uebersendung ich Miss M. A. Pocock verdanke. Im Zell- und Zygotenbau, wie überhaupt in allen bisher bekannten Eigenschaften außer der Temperaturresistenz der Zygoten stimmt die Form mit f. typica überein. Die Zygoten von f. typica und f. romadeos haben eine relativ dicke, warzige Membran. Die Membranstärke ist einer Messung zugänglich. Vom Protoplasten bis zum Ende der Warzen beträgt der Abstand 2—2,5 μ. Wenn daher als Zygotendurchmesser 12 μ angegeben wird, dann ist der Membrananteil 4—5 μ.

Im Jahre 1940 wurde eine alte Erdprobe, die aus der Umgebung von Königsberg 1931 gesammelt wurde, wieder mit Erdabkochung übergossen. Es entwickelte sich eine eugametos-ähnliche Form. Die Prüfung an Klonen ergab, daß diese sich in zwei der bisher bekannten Eigenschaften von f. typica unterscheidet. Die Zygoten haben eine sehr dünne, glatte Membran. Die Membranstärke liegt unter 0,5 μ; sie läßt sich nicht mehr genau bestimmen. Gegen erhöhte Temperaturen sind die Zygoten sehr empfindlich. Ihre obere Temperaturgrenze liegt bei 45° C. Dieser Stamm wird als eine Form von Chlamydomonas eugametos aufgefaßt. Diese Rasse wurde f. Hartmanni genannt.

Analyse der Bastardzygoten: Die beiden eben erwähnten Rassen von Chlamydomonas eugametos, f. romadeos und f. Hartmanni, wurden mit einander gekreuzt. Die Kreuzung selbst bereitet keine Schwierigkeiten. Beide Rassen sind diözisch. Die Keimung der Bastardzygoten ist in keiner Weise beeinträchtigt. Unter den in Leitungswasser und bei Zimmertemperatur aufbewahrten Zygoten liegt der Anteil grau gefärbter Zygoten unter 1%. Er ist ebenso hoch wie bei den Elternrassen. Folgende zwei Eigenschaften wurden analysiert: 1. die Zygotenmembran, 2. die Temperaturresistenz. Die f. romadeos hat eine dicke, warzige Membran und eine 75°-Resistenz, die f. Hartmanni eine dünne, glatte Membran und eine 45°-Resistenz. Beide Merkmale treten in der Diplophase in Erscheinung, die bei der Gattung Chlamydomonas nur auf die Zygote beschränkt ist. Es ist also mit Dominanz zu rechnen, im Gegensatz zu Merkmalen der Haplophase, wie wir es sonst bei Chlamydomonas gewöhnt sind.

Die F$_1$-Bastard-Zygoten haben eine dicke, warzige Membran. Es dominiert also der romadeos-Phänotyp. Die Prüfung der Temperaturresistenz ergibt sich aus Tabelle 1. Bei 45° sind 2,2%, bei 60° 19,9%, bei 75° 47,9% der Zygoten entfärbt, während bei Zimmertemperatur nur 0,7% der Zygoten grau gefärbt sind. Der Sicherheit halber wurde nachträglich noch eine Bestimmung bei 70° ausgeführt. Sie ergab 31,8% abgestorbene Zygoten. Die obere Temperaturgrenze der F$_1$-Bastardzygoten liegt also bei 75°, wie bei f. romadeos. Die reziproken Kreuzungen liefern F$_1$-Bastardzygoten mit gleichen Eigenschaften.

Tabelle 1

		im mm^3	im mm^3	im mm^3	Summe	%	Zahl der beobachteten Zygoten
45°	grün	108	90	111	309	97,8	316 (+ 2)

Figure A.110: Culture methods and genetic analysis of *Chlamydomonas* algae to engineer robust microorganisms for biotechnology applications [FIAT 964].

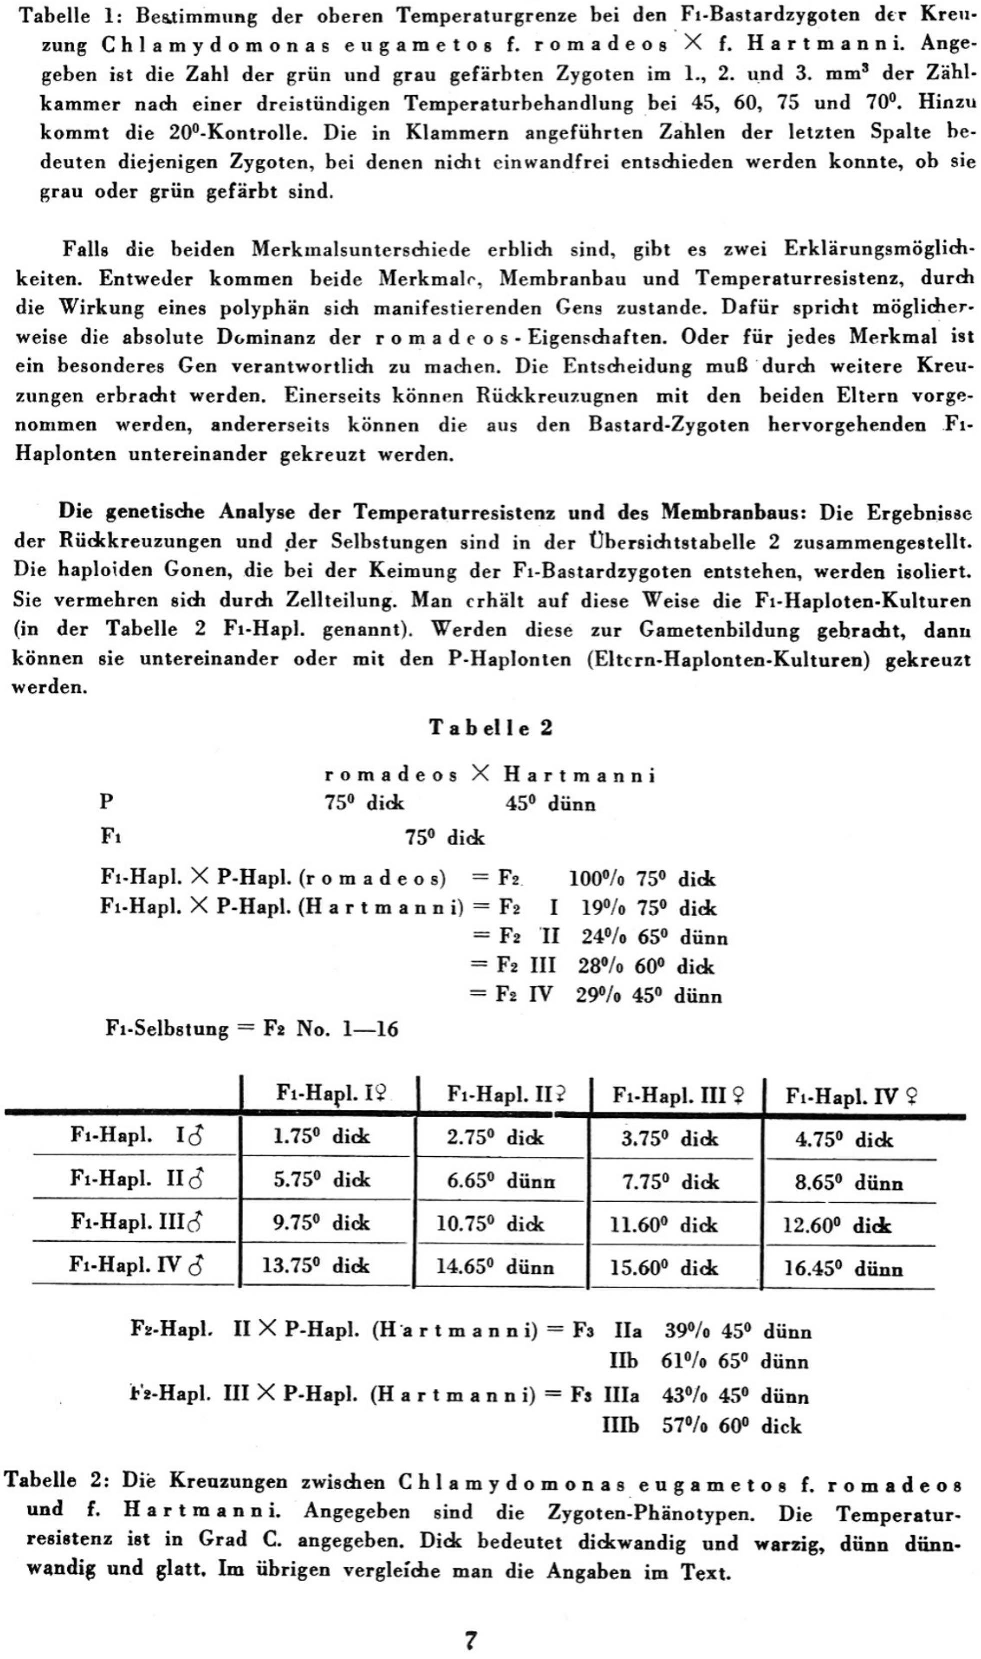

Tabelle 1: Bestimmung der oberen Temperaturgrenze bei den F_1-Bastardzygoten der Kreuzung Chlamydomonas eugametos f. romadeos × f. Hartmanni. Angegeben ist die Zahl der grün und grau gefärbten Zygoten im 1., 2. und 3. mm^3 der Zählkammer nach einer dreistündigen Temperaturbehandlung bei 45, 60, 75 und 70°. Hinzu kommt die 20°-Kontrolle. Die in Klammern angeführten Zahlen der letzten Spalte bedeuten diejenigen Zygoten, bei denen nicht einwandfrei entschieden werden konnte, ob sie grau oder grün gefärbt sind.

Falls die beiden Merkmalsunterschiede erblich sind, gibt es zwei Erklärungsmöglichkeiten. Entweder kommen beide Merkmale, Membranbau und Temperaturresistenz, durch die Wirkung eines polyphän sich manifestierenden Gens zustande. Dafür spricht möglicherweise die absolute Dominanz der romadeos-Eigenschaften. Oder für jedes Merkmal ist ein besonderes Gen verantwortlich zu machen. Die Entscheidung muß durch weitere Kreuzungen erbracht werden. Einerseits können Rückkreuzugnen mit den beiden Eltern vorgenommen werden, andererseits können die aus den Bastard-Zygoten hervorgehenden F_1-Haplonten untereinander gekreuzt werden.

Die genetische Analyse der Temperaturresistenz und des Membranbaus: Die Ergebnisse der Rückkreuzungen und der Selbstungen sind in der Übersichtstabelle 2 zusammengestellt. Die haploiden Gonen, die bei der Keimung der F_1-Bastardzygoten entstehen, werden isoliert. Sie vermehren sich durch Zellteilung. Man erhält auf diese Weise die F_1-Haploten-Kulturen (in der Tabelle 2 F_1-Hapl. genannt). Werden diese zur Gametenbildung gebracht, dann können sie untereinander oder mit den P-Haplonten (Eltern-Haplonten-Kulturen) gekreuzt werden.

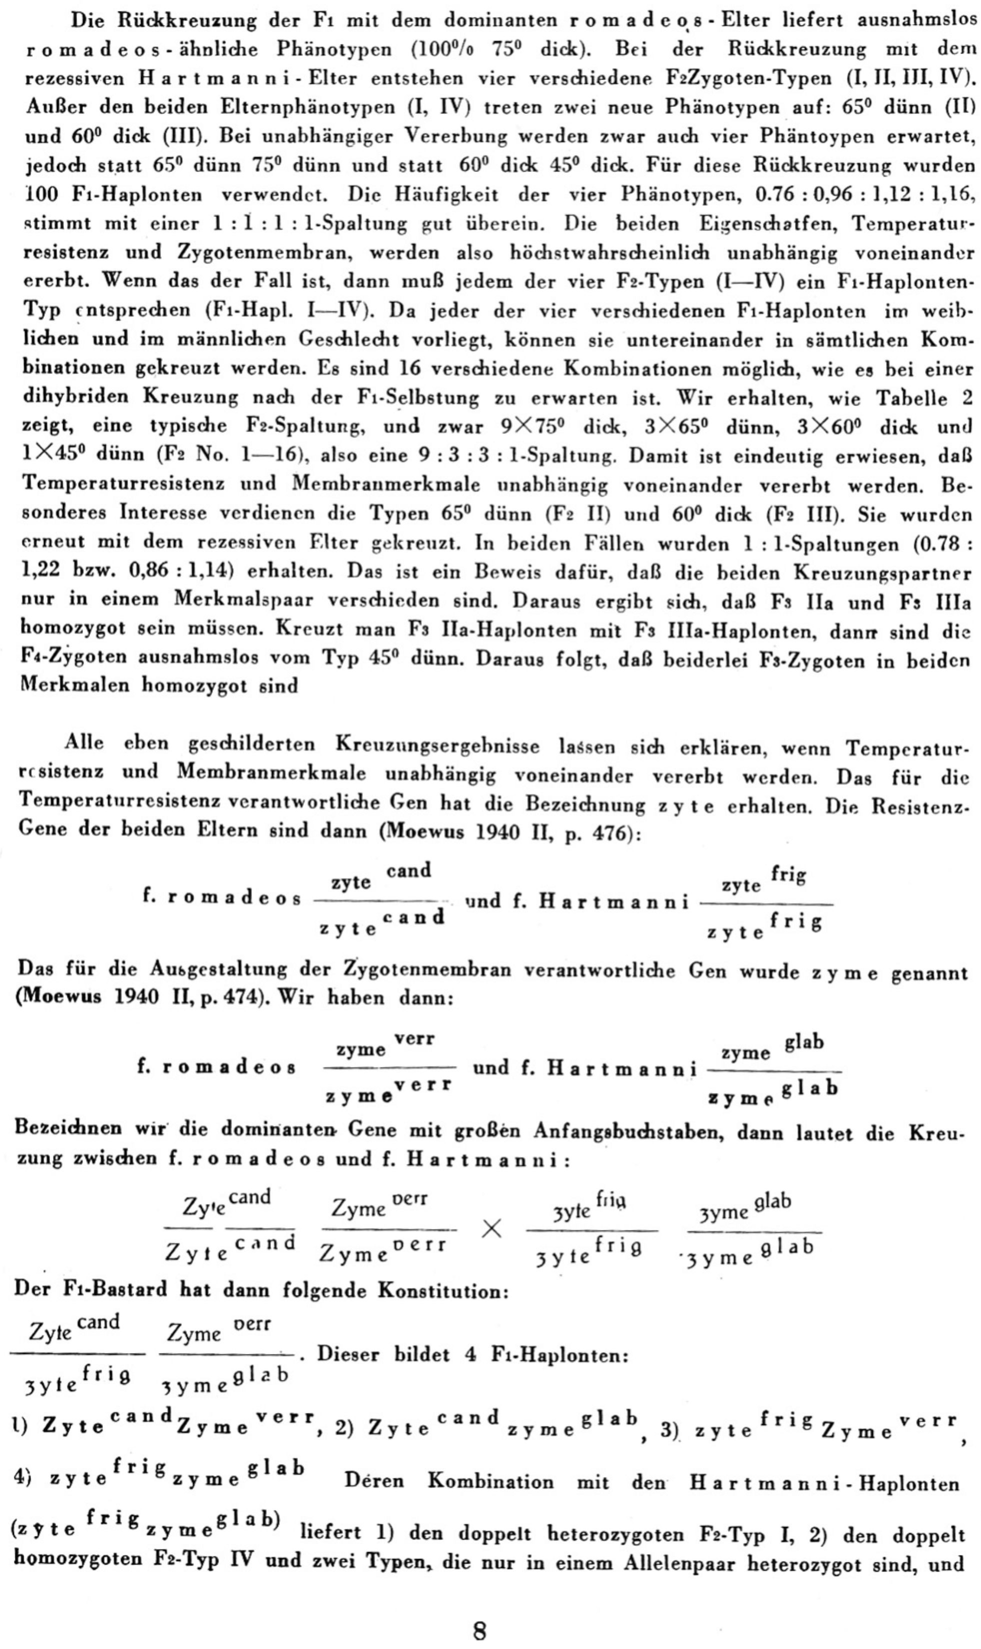
F_2-Hapl. III × P-Hapl. (Hartmanni) = F_3 IIIa 43% 45° dünn
IIIb 57% 60° dick

Tabelle 2: Die Kreuzungen zwischen Chlamydomonas eugametos f. romadeos und f. Hartmanni. Angegeben sind die Zygoten-Phänotypen. Die Temperaturresistenz ist in Grad C. angegeben. Dick bedeutet dickwandig und warzig, dünn dünnwandig und glatt. Im übrigen vergleiche man die Angaben im Text.

7

Figure A.111: Culture methods and genetic analysis of *Chlamydomonas* algae to engineer robust microorganisms for biotechnology applications [FIAT 964].



Die Rückkreuzung der F_1 mit dem dominanten romadeos-Elter liefert ausnahmslos romadeos-ähnliche Phänotypen (100% 75° dick). Bei der Rückkreuzung mit dem rezessiven Hartmanni-Elter entstehen vier verschiedene F_2Zygoten-Typen (I, II, III, IV). Außer den beiden Elternphänotypen (I, IV) treten zwei neue Phänotypen auf: 65° dünn (II) und 60° dick (III). Bei unabhängiger Vererbung werden zwar auch vier Phäntoypen erwartet, jedoch statt 65° dünn 75° dünn und statt 60° dick 45° dick. Für diese Rückkreuzung wurden 100 F_1-Haplonten verwendet. Die Häufigkeit der vier Phänotypen, 0.76 : 0,96 : 1,12 : 1,16, stimmt mit einer 1 : 1 : 1 : 1-Spaltung gut überein. Die beiden Eigenschatfen, Temperaturresistenz und Zygotenmembran, werden also höchstwahrscheinlich unabhängig voneinander ererbt. Wenn das der Fall ist, dann muß jedem der vier F_2-Typen (I—IV) ein F_1-Haplonten-Typ entsprechen (F_1-Hapl. I—IV). Da jeder der vier verschiedenen F_1-Haplonten im weiblichen und im männlichen Geschlecht vorliegt, können sie untereinander in sämtlichen Kombinationen gekreuzt werden. Es sind 16 verschiedene Kombinationen möglich, wie es bei einer dihybriden Kreuzung nach der F_1-Selbstung zu erwarten ist. Wir erhalten, wie Tabelle 2 zeigt, eine typische F_2-Spaltung, und zwar 9×75° dick, 3×65° dünn, 3×60° dick und 1×45° dünn (F_2 No. 1—16), also eine 9 : 3 : 3 : 1-Spaltung. Damit ist eindeutig erwiesen, daß Temperaturresistenz und Membranmerkmale unabhängig voneinander vererbt werden. Besonderes Interesse verdienen die Typen 65° dünn (F_2 II) und 60° dick (F_2 III). Sie wurden erneut mit dem rezessiven Elter gekreuzt. In beiden Fällen wurden 1 : 1-Spaltungen (0.78 : 1,22 bzw. 0,86 : 1,14) erhalten. Das ist ein Beweis dafür, daß die beiden Kreuzungspartner nur in einem Merkmalspaar verschieden sind. Daraus ergibt sich, daß F_3 IIa und F_3 IIIa homozygot sein müssen. Kreuzt man F_3 IIa-Haplonten mit F_3 IIIa-Haplonten, dann sind die F_4-Zygoten ausnahmslos vom Typ 45° dünn. Daraus folgt, daß beiderlei F_3-Zygoten in beiden Merkmalen homozygot sind

Alle eben geschilderten Kreuzungsergebnisse lassen sich erklären, wenn Temperaturresistenz und Membranmerkmale unabhängig voneinander vererbt werden. Das für die Temperaturresistenz verantwortliche Gen hat die Bezeichnung zyte erhalten. Die Resistenz-Gene der beiden Eltern sind dann (Moewus 1940 II, p. 476):

$$\text{f. romadeos}\ \frac{\text{zyte}^{\text{cand}}}{\text{zyte}^{\text{cand}}}\ \text{und f. Hartmanni}\ \frac{\text{zyte}^{\text{frig}}}{\text{zyte}^{\text{frig}}}$$

Das für die Ausgestaltung der Zygotenmembran verantwortliche Gen wurde zyme genannt (Moewus 1940 II, p. 474). Wir haben dann:

$$\text{f. romadeos}\ \frac{\text{zyme}^{\text{verr}}}{\text{zyme}^{\text{verr}}}\ \text{und f. Hartmanni}\ \frac{\text{zyme}^{\text{glab}}}{\text{zyme}^{\text{glab}}}$$

Bezeichnen wir die dominanten Gene mit großen Anfangsbuchstaben, dann lautet die Kreuzung zwischen f. romadeos und f. Hartmanni:

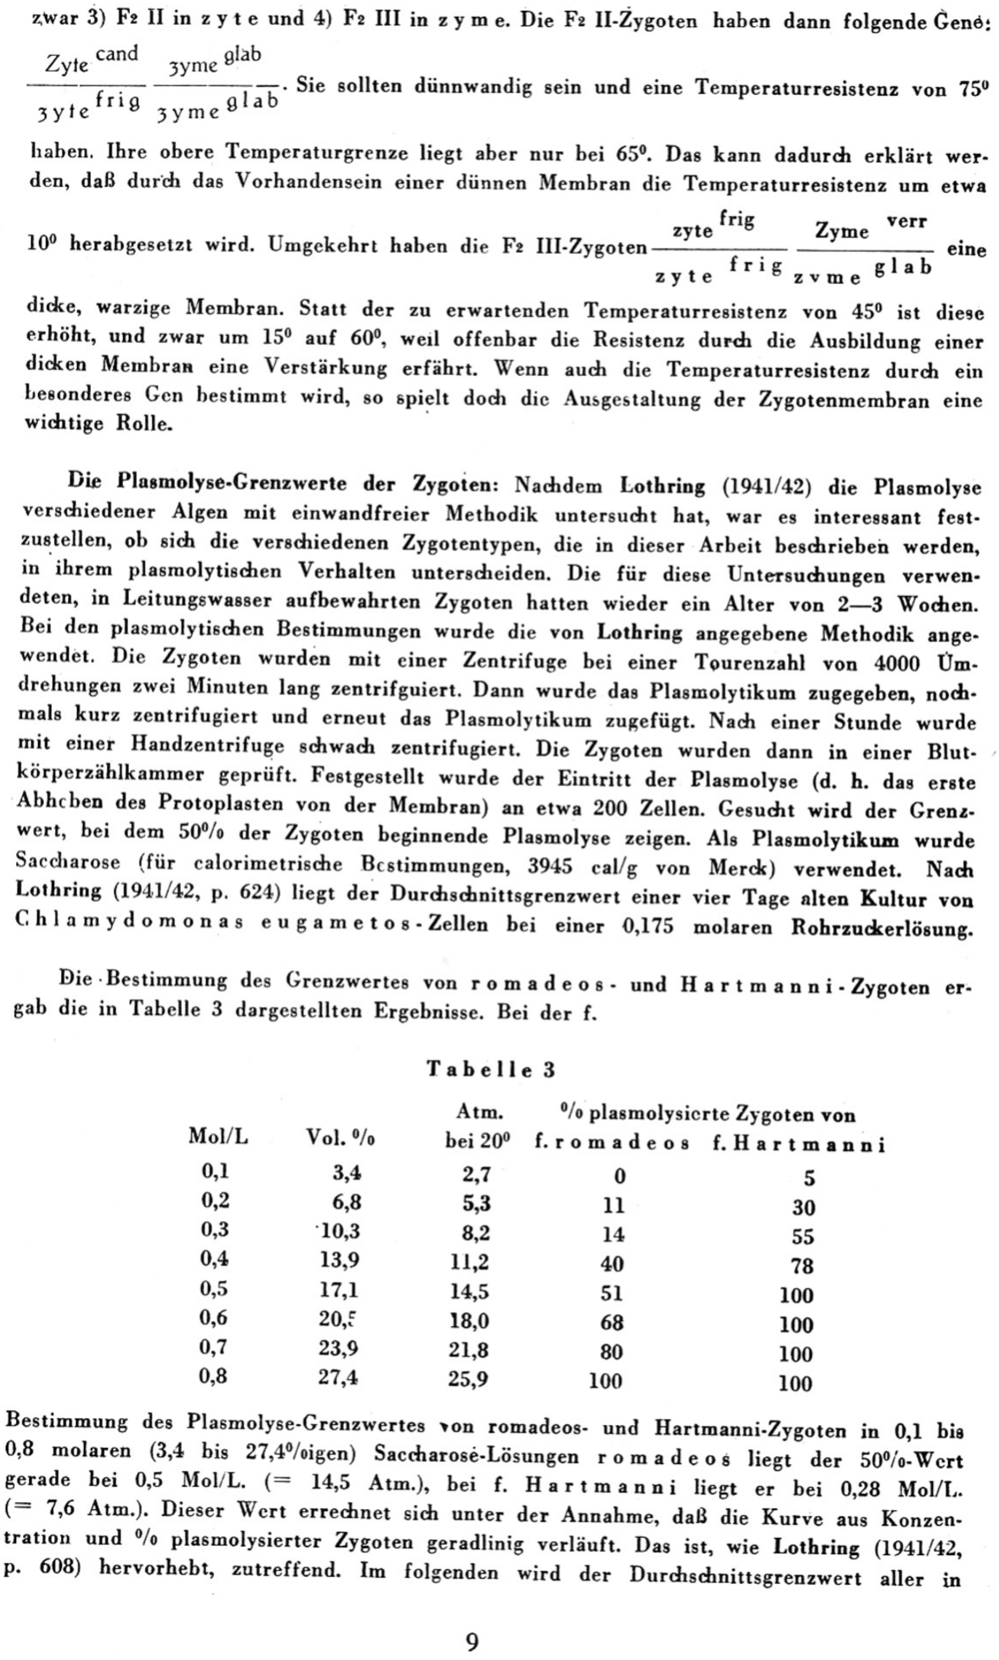
$$\frac{\text{Zyte}^{\text{cand}}}{\text{Zyte}^{\text{cand}}}\ \frac{\text{Zyme}^{\text{verr}}}{\text{Zyme}^{\text{verr}}} \times \frac{\text{zyte}^{\text{frig}}}{\text{zyte}^{\text{frig}}}\ \frac{\text{zyme}^{\text{glab}}}{\text{zyme}^{\text{glab}}}$$

Der F_1-Bastard hat dann folgende Konstitution:

$\dfrac{\text{Zyte}^{\text{cand}}}{\text{zyte}^{\text{frig}}}\ \dfrac{\text{Zyme}^{\text{verr}}}{\text{zyme}^{\text{glab}}}$. Dieser bildet 4 F_1-Haplonten:

1) $\text{Zyte}^{\text{cand}}\text{Zyme}^{\text{verr}}$, 2) $\text{Zyte}^{\text{cand}}\text{zyme}^{\text{glab}}$, 3) $\text{zyte}^{\text{frig}}\text{Zyme}^{\text{verr}}$, 4) $\text{zyte}^{\text{frig}}\text{zyme}^{\text{glab}}$ Deren Kombination mit den Hartmanni-Haplonten ($\text{zyte}^{\text{frig}}\text{zyme}^{\text{glab}}$) liefert 1) den doppelt heterozygoten F_2-Typ I, 2) den doppelt homozygoten F_2-Typ IV und zwei Typen, die nur in einem Allelenpaar heterozygot sind, und

Figure A.112: Culture methods and genetic analysis of *Chlamydomonas* algae to engineer robust microorganisms for biotechnology applications [FIAT 964].



zwar 3) F_2 II in zyte und 4) F_2 III in zyme. Die F_2 II-Zygoten haben dann folgende Gene: $\frac{\text{Zyte}^{\text{cand}}}{\text{ʒyte}^{\text{frig}}}\ \frac{\text{ʒyme}^{\text{glab}}}{\text{ʒyme}^{\text{glab}}}$. Sie sollten dünnwandig sein und eine Temperaturresistenz von 75° haben. Ihre obere Temperaturgrenze liegt aber nur bei 65°. Das kann dadurch erklärt werden, daß durch das Vorhandensein einer dünnen Membran die Temperaturresistenz um etwa 10° herabgesetzt wird. Umgekehrt haben die F_2 III-Zygoten $\frac{\text{zyte}^{\text{frig}}}{\text{zyte}^{\text{frig}}}\ \frac{\text{Zyme}^{\text{verr}}}{\text{zyme}^{\text{glab}}}$ eine dicke, warzige Membran. Statt der zu erwartenden Temperaturresistenz von 45° ist diese erhöht, und zwar um 15° auf 60°, weil offenbar die Resistenz durch die Ausbildung einer dicken Membran eine Verstärkung erfährt. Wenn auch die Temperaturresistenz durch ein besonderes Gen bestimmt wird, so spielt doch die Ausgestaltung der Zygotenmembran eine wichtige Rolle.

Die Plasmolyse-Grenzwerte der Zygoten: Nachdem **Lothring** (1941/42) die Plasmolyse verschiedener Algen mit einwandfreier Methodik untersucht hat, war es interessant festzustellen, ob sich die verschiedenen Zygotentypen, die in dieser Arbeit beschrieben werden, in ihrem plasmolytischen Verhalten unterscheiden. Die für diese Untersuchungen verwendeten, in Leitungswasser aufbewahrten Zygoten hatten wieder ein Alter von 2—3 Wochen. Bei den plasmolytischen Bestimmungen wurde die von **Lothring** angegebene Methodik angewendet. Die Zygoten wurden mit einer Zentrifuge bei einer Tourenzahl von 4000 Umdrehungen zwei Minuten lang zentrifguiert. Dann wurde das Plasmolytikum zugegeben, nochmals kurz zentrifugiert und erneut das Plasmolytikum zugefügt. Nach einer Stunde wurde mit einer Handzentrifuge schwach zentrifugiert. Die Zygoten wurden dann in einer Blutkörperzählkammer geprüft. Festgestellt wurde der Eintritt der Plasmolyse (d. h. das erste Abheben des Protoplasten von der Membran) an etwa 200 Zellen. Gesucht wird der Grenzwert, bei dem 50% der Zygoten beginnende Plasmolyse zeigen. Als Plasmolytikum wurde Saccharose (für calorimetrische Bestimmungen, 3945 cal/g von Merck) verwendet. Nach **Lothring** (1941/42, p. 624) liegt der Durchschnittsgrenzwert einer vier Tage alten Kultur von Chlamydomonas eugametos-Zellen bei einer 0,175 molaren Rohrzuckerlösung.

Die Bestimmung des Grenzwertes von romadeos- und Hartmanni-Zygoten ergab die in Tabelle 3 dargestellten Ergebnisse. Bei der f.

Tabelle 3

Mol/L	Vol. %	Atm. bei 20°	% plasmolysierte Zygoten von f. romadeos	f. Hartmanni
0,1	3,4	2,7	0	5
0,2	6,8	5,3	11	30
0,3	10,3	8,2	14	55
0,4	13,9	11,2	40	78
0,5	17,1	14,5	51	100
0,6	20,5	18,0	68	100
0,7	23,9	21,8	80	100
0,8	27,4	25,9	100	100

Bestimmung des Plasmolyse-Grenzwertes von romadeos- und Hartmanni-Zygoten in 0,1 bis 0,8 molaren (3,4 bis 27,4%igen) Saccharose-Lösungen romadeos liegt der 50%-Wert gerade bei 0,5 Mol/L. (= 14,5 Atm.), bei f. Hartmanni liegt er bei 0,28 Mol/L. (= 7,6 Atm.). Dieser Wert errechnet sich unter der Annahme, daß die Kurve aus Konzentration und % plasmolysierter Zygoten geradlinig verläuft. Das ist, wie **Lothring** (1941/42, p. 608) hervorhebt, zutreffend. Im folgenden wird der Durchschnittsgrenzwert aller in

Figure A.113: Culture methods and genetic analysis of *Chlamydomonas* algae to engineer robust microorganisms for biotechnology applications [FIAT 964].

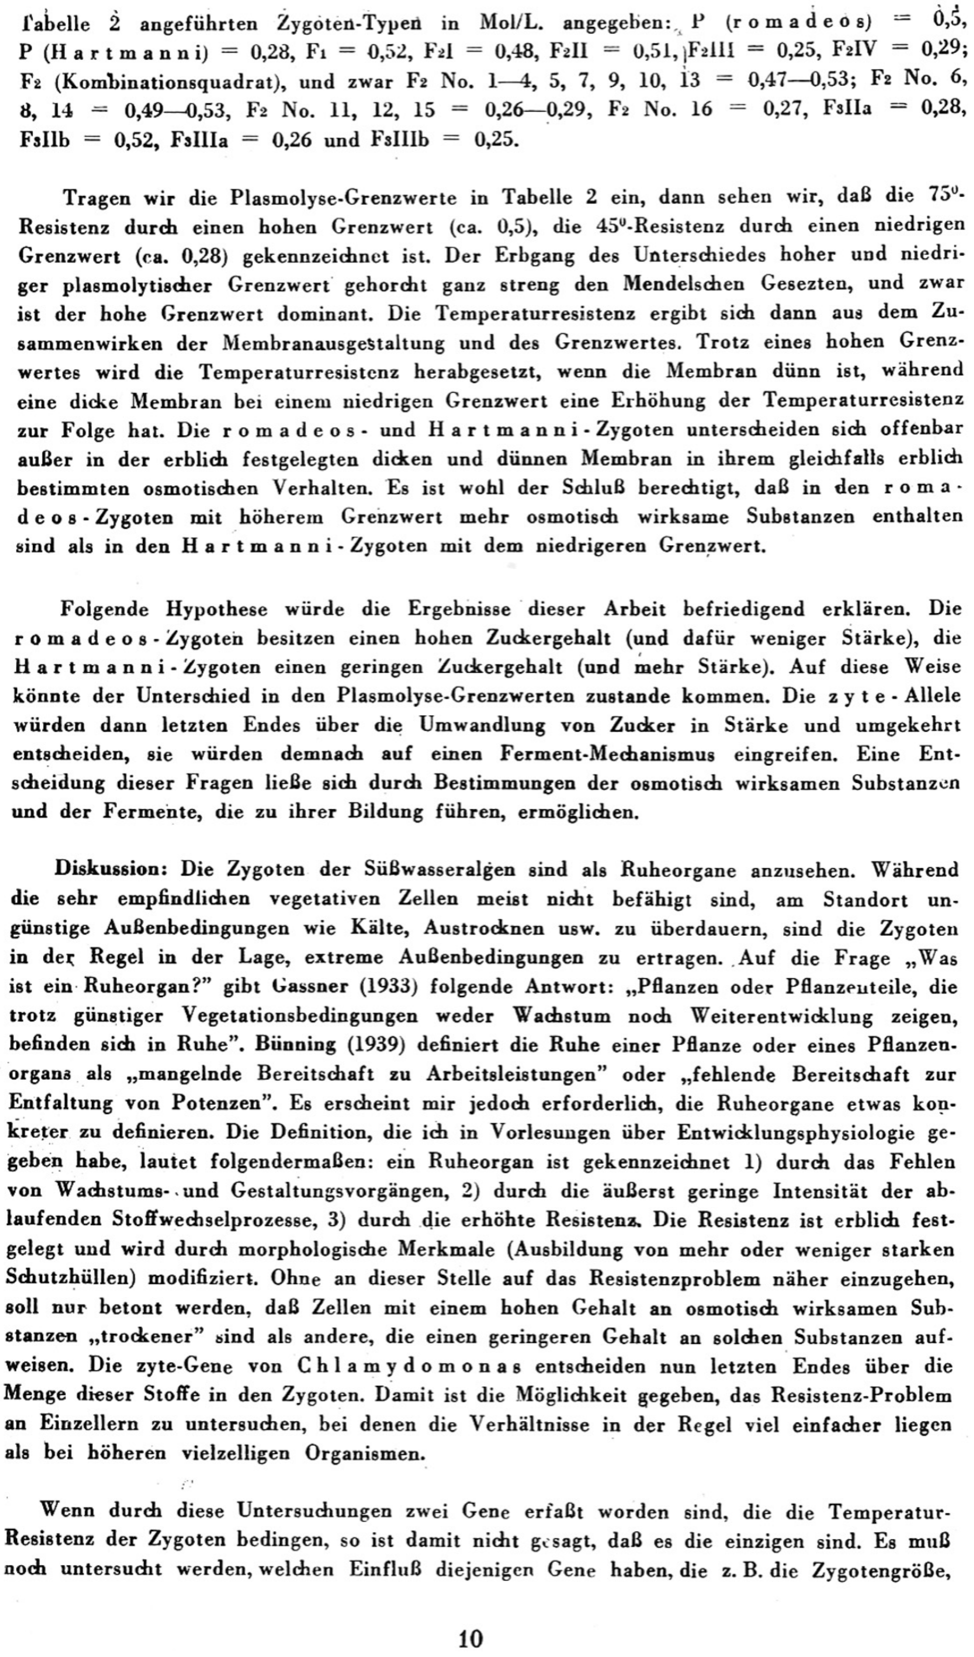


Tabelle 2 angeführten Zygoten-Typen in Mol/L. angegeben: P (romadeos) = 0,5, P (Hartmanni) = 0,28, F_1 = 0,52, F_2I = 0,48, F_2II = 0,51, F_2III = 0,25, F_2IV = 0,29; F_2 (Kombinationsquadrat), und zwar F_2 No. 1—4, 5, 7, 9, 10, 13 = 0,47—0,53; F_2 No. 6, 8, 14 = 0,49—0,53, F_2 No. 11, 12, 15 = 0,26—0,29, F_2 No. 16 = 0,27, F_3IIa = 0,28, F_3IIb = 0,52, F_3IIIa = 0,26 und F_3IIIb = 0,25.

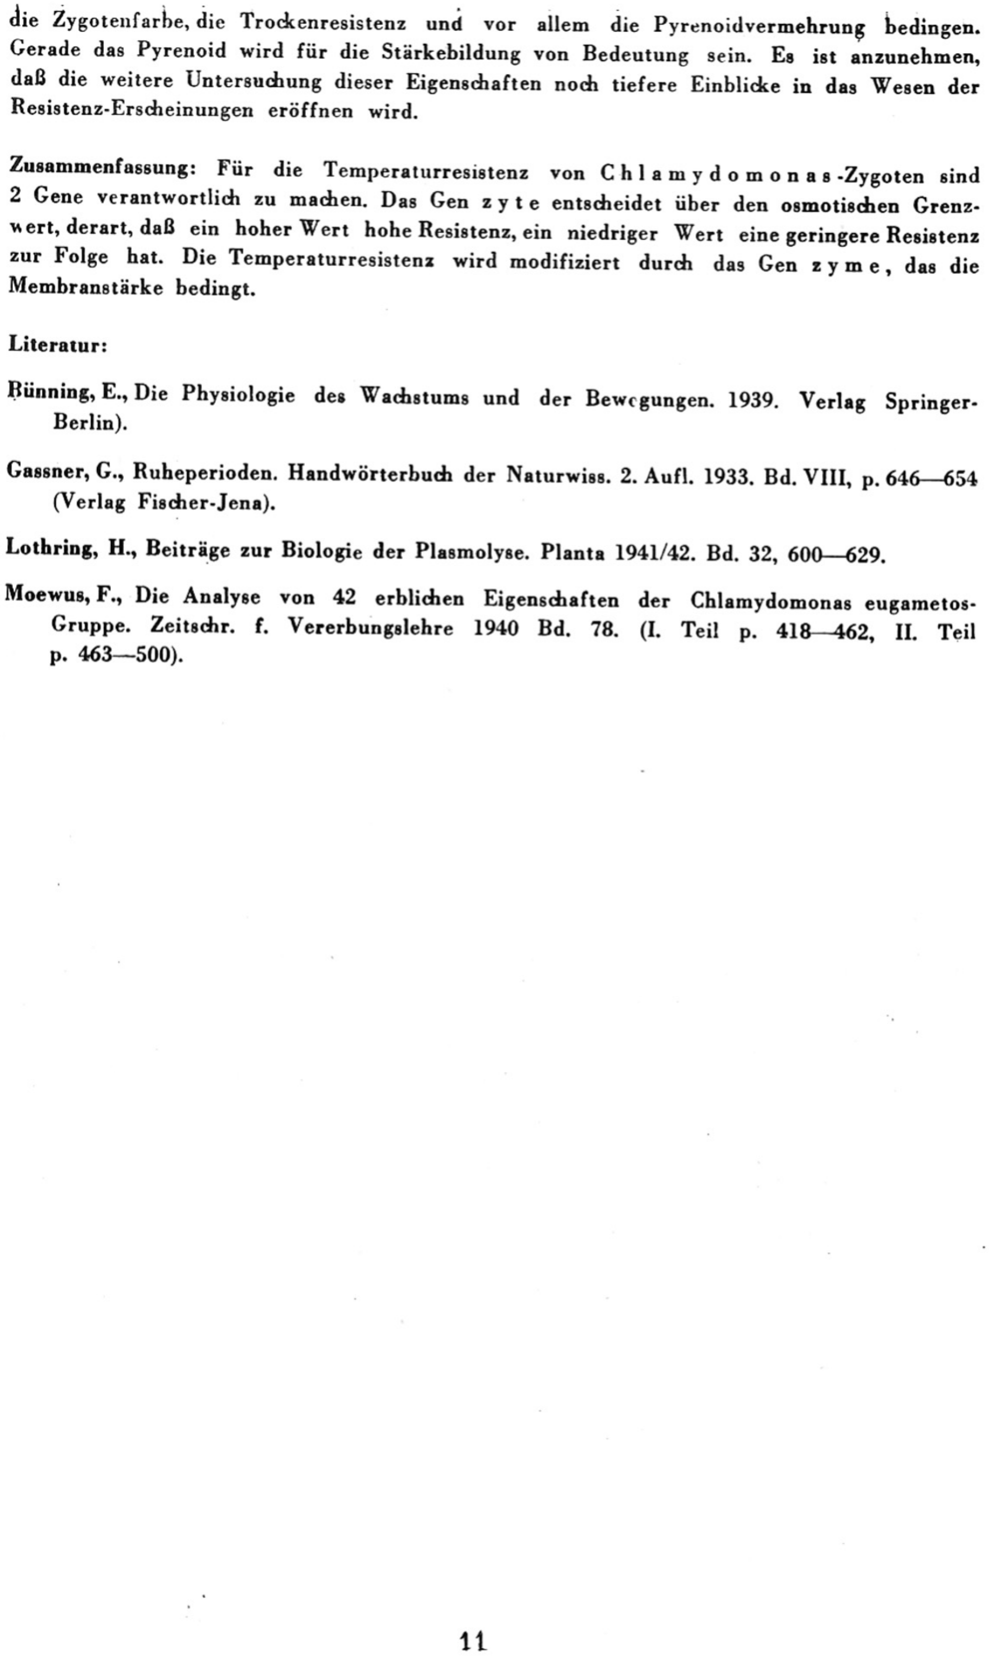
Tragen wir die Plasmolyse-Grenzwerte in Tabelle 2 ein, dann sehen wir, daß die 75°-Resistenz durch einen hohen Grenzwert (ca. 0,5), die 45°-Resistenz durch einen niedrigen Grenzwert (ca. 0,28) gekennzeichnet ist. Der Erbgang des Unterschiedes hoher und niedriger plasmolytischer Grenzwert gehorcht ganz streng den Mendelschen Gesezten, und zwar ist der hohe Grenzwert dominant. Die Temperaturresistenz ergibt sich dann aus dem Zusammenwirken der Membranausgestaltung und des Grenzwertes. Trotz eines hohen Grenzwertes wird die Temperaturresistenz herabgesetzt, wenn die Membran dünn ist, während eine dicke Membran bei einem niedrigen Grenzwert eine Erhöhung der Temperaturresistenz zur Folge hat. Die romadeos- und Hartmanni-Zygoten unterscheiden sich offenbar außer in der erblich festgelegten dicken und dünnen Membran in ihrem gleichfalls erblich bestimmten osmotischen Verhalten. Es ist wohl der Schluß berechtigt, daß in den romadeos-Zygoten mit höherem Grenzwert mehr osmotisch wirksame Substanzen enthalten sind als in den Hartmanni-Zygoten mit dem niedrigeren Grenzwert.

Folgende Hypothese würde die Ergebnisse dieser Arbeit befriedigend erklären. Die romadeos-Zygoten besitzen einen hohen Zuckergehalt (und dafür weniger Stärke), die Hartmanni-Zygoten einen geringen Zuckergehalt (und mehr Stärke). Auf diese Weise könnte der Unterschied in den Plasmolyse-Grenzwerten zustande kommen. Die zyte-Allele würden dann letzten Endes über die Umwandlung von Zucker in Stärke und umgekehrt entscheiden, sie würden demnach auf einen Ferment-Mechanismus eingreifen. Eine Entscheidung dieser Fragen ließe sich durch Bestimmungen der osmotisch wirksamen Substanzen und der Fermente, die zu ihrer Bildung führen, ermöglichen.

Diskussion: Die Zygoten der Süßwasseralgen sind als Ruheorgane anzusehen. Während die sehr empfindlichen vegetativen Zellen meist nicht befähigt sind, am Standort ungünstige Außenbedingungen wie Kälte, Austrocknen usw. zu überdauern, sind die Zygoten in der Regel in der Lage, extreme Außenbedingungen zu ertragen. Auf die Frage „Was ist ein Ruheorgan?" gibt Gassner (1933) folgende Antwort: „Pflanzen oder Pflanzenteile, die trotz günstiger Vegetationsbedingungen weder Wachstum noch Weiterentwicklung zeigen, befinden sich in Ruhe". Bünning (1939) definiert die Ruhe einer Pflanze oder eines Pflanzenorgans als „mangelnde Bereitschaft zu Arbeitsleistungen" oder „fehlende Bereitschaft zur Entfaltung von Potenzen". Es erscheint mir jedoch erforderlich, die Ruheorgane etwas konkreter zu definieren. Die Definition, die ich in Vorlesungen über Entwicklungsphysiologie gegeben habe, lautet folgendermaßen: ein Ruheorgan ist gekennzeichnet 1) durch das Fehlen von Wachstums- und Gestaltungsvorgängen, 2) durch die äußerst geringe Intensität der ablaufenden Stoffwechselprozesse, 3) durch die erhöhte Resistenz. Die Resistenz ist erblich festgelegt und wird durch morphologische Merkmale (Ausbildung von mehr oder weniger starken Schutzhüllen) modifiziert. Ohne an dieser Stelle auf das Resistenzproblem näher einzugehen, soll nur betont werden, daß Zellen mit einem hohen Gehalt an osmotisch wirksamen Substanzen „trockener" sind als andere, die einen geringeren Gehalt an solchen Substanzen aufweisen. Die zyte-Gene von Chlamydomonas entscheiden nun letzten Endes über die Menge dieser Stoffe in den Zygoten. Damit ist die Möglichkeit gegeben, das Resistenz-Problem an Einzellern zu untersuchen, bei denen die Verhältnisse in der Regel viel einfacher liegen als bei höheren vielzelligen Organismen.

Wenn durch diese Untersuchungen zwei Gene erfaßt worden sind, die die Temperatur-Resistenz der Zygoten bedingen, so ist damit nicht gesagt, daß es die einzigen sind. Es muß noch untersucht werden, welchen Einfluß diejenigen Gene haben, die z. B. die Zygotengröße,

Figure A.114: Culture methods and genetic analysis of *Chlamydomonas* algae to engineer robust microorganisms for biotechnology applications [FIAT 964].



die Zygotenfarbe, die Trockenresistenz und vor allem die Pyrenoidvermehrung bedingen. Gerade das Pyrenoid wird für die Stärkebildung von Bedeutung sein. Es ist anzunehmen, daß die weitere Untersuchung dieser Eigenschaften noch tiefere Einblicke in das Wesen der Resistenz-Erscheinungen eröffnen wird.

Zusammenfassung: Für die Temperaturresistenz von Chlamydomonas-Zygoten sind 2 Gene verantwortlich zu machen. Das Gen zyte entscheidet über den osmotischen Grenzwert, derart, daß ein hoher Wert hohe Resistenz, ein niedriger Wert eine geringere Resistenz zur Folge hat. Die Temperaturresistenz wird modifiziert durch das Gen zyme, das die Membranstärke bedingt.

FIAT 996. ***The Commercial Development and Manufacture of Synthetic Hormones in Germany.***

The technical development of the synthesis of the estrogenic, androgenic, and adrenal cortical hormones and of the manufacturing processes employed in Germany for their commercial production from cholesterol and stigmasterol are reviewed. Procedures for the preparation of testosterone and progesterone from dehydroandrosterone, for the conversion of hydroxyetiocholenic acid to desoxycorticosterone, for the transformation of acetoxybisnorcholenic acid to progesterone and desoxycorticosterone, and for the reduction of estrone to estriol are described and charted. Full manufacturing details of the Schering A.G. processes for the synthesis of hormones from cholesterol and of the Schering and I.G. Farbenindustrie processes for the synthesis of progesterone from phytosterol are discussed. The original German processes are collected in an appendix. A further appendix gives a transcript of a patent application for the preparation of estradiol and other related compounds of the cyclopentanopolyhydrophenanthrene series.

[This very long report describes many of the details of the commercial synthesis of a variety of steroid hormones. Please see pp. 2462–2470 for some of the pages from this report.

CIOS XXV-54, *Pharmaceuticals at I.G. Farbenindustrie Plant Elberfeld*, also covers some related work.]

THE MANUFACTURE OF SYNTHETIC HORMONES IN GERMANY

By the above processes worked out and developed in the research laboratories of Schering A.G., and the I.G. Farbenindustriewerke, the manufacture and distribution of synthetic hormones provided a useful and important addition to the armamentarium of the practising physician in Germany.

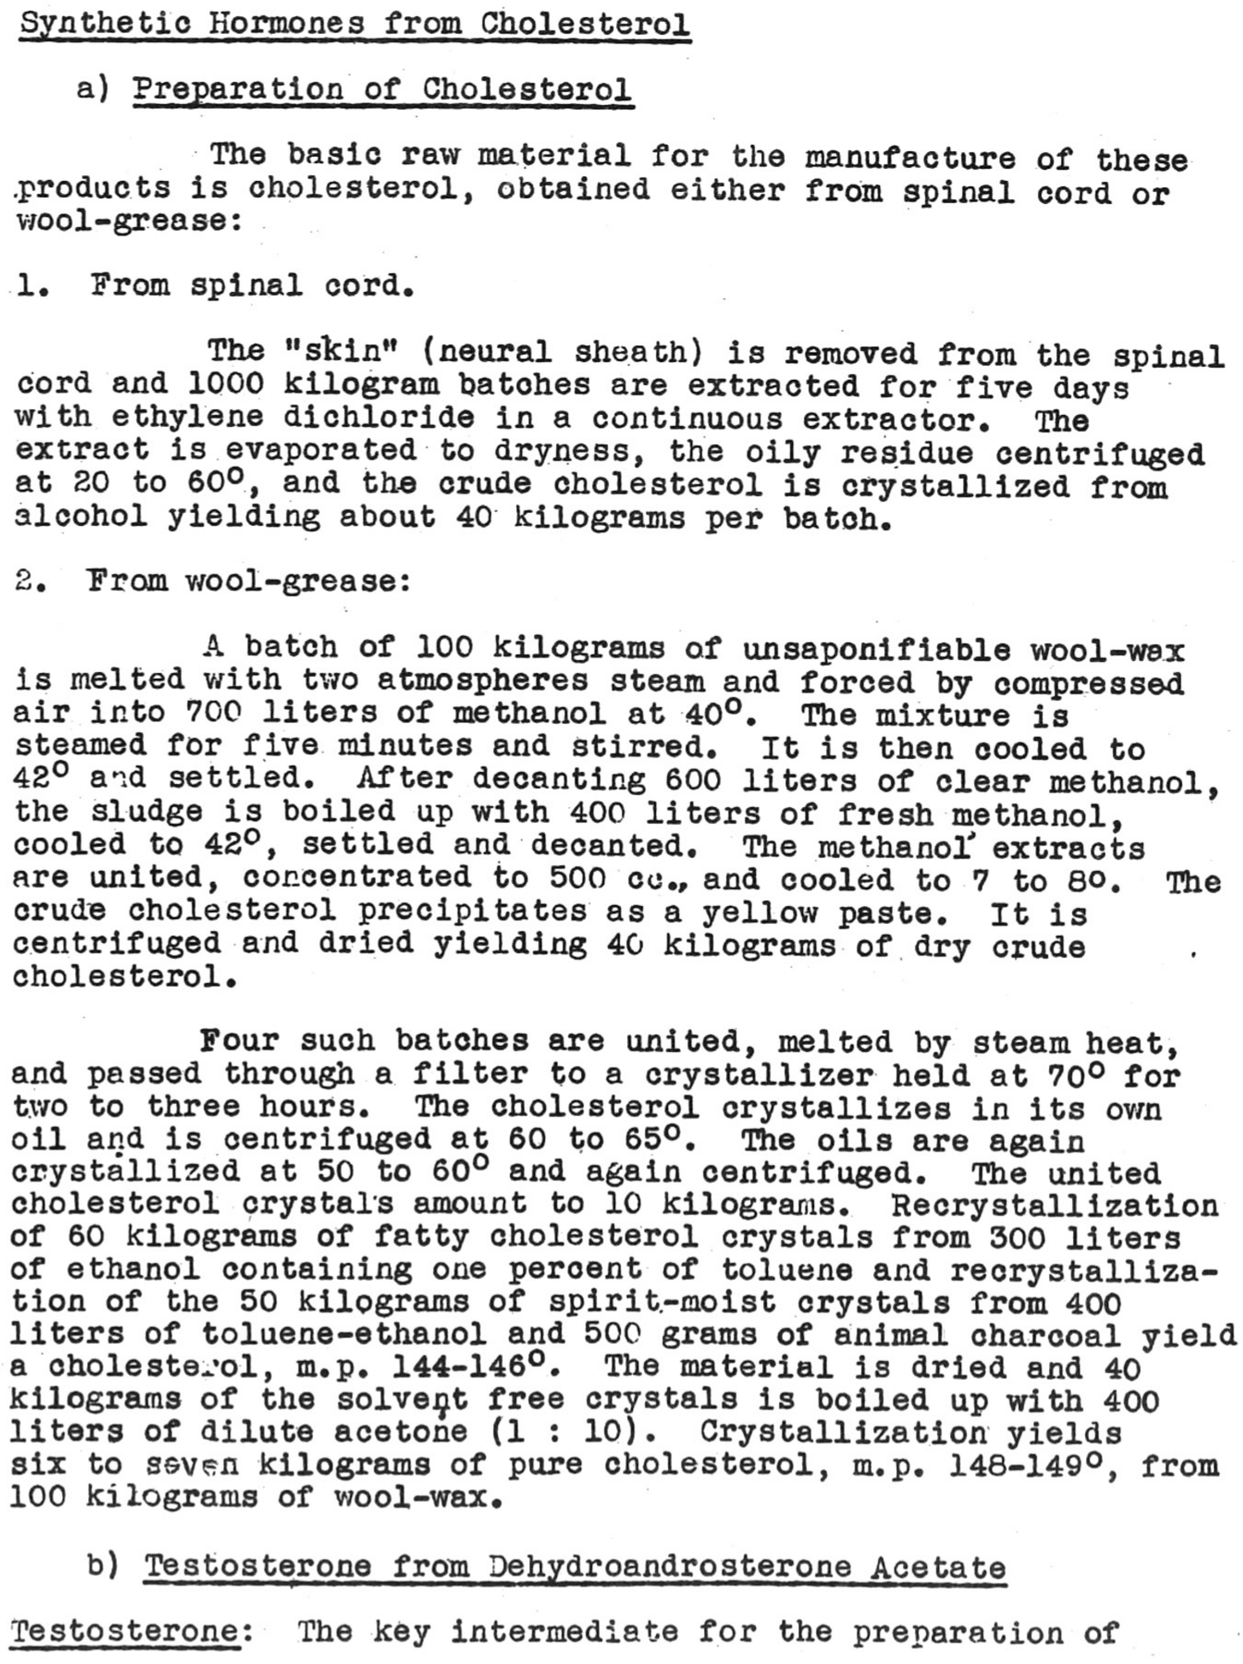
The commercial development of the synthetic hormones by Schering A.G., is illustrated by the following list of specialities and their production (in grams per year) during the years 1938-1942:

	1938	1939	1940	1941	1942
Androsterone Benzoate ...	350	422	--	--	--
Desoxycorticosterone Acetate (Cortiron)......	--	1,177	1,340	2,544	3,751
Estradiol	959	1,081	5,815	14,695	18,971
Estradiol Benzoate (Progynon B)	6,115	8,765	5,088	7,546	10,040
Estradiol Dipropionate (Progynon d.p.).........	340	275	--	723	--
Pregneninolone (Proluton C)............	--	--	5,512	36,013	16,564
Progesterone (Proluton)..	4,590	9,724	5,122	2,310	6,101
Testosterone Propionate (Testoviron)............	14,393	27,684	18,849	33,749	27,182

The bulk pharmaceutical production of Schering A.G., was formerly carried on at Berlin-Aldershof. War demolition and dismounting of equipment have seriously interrupted the flow of the intermediates for synthetic hormones previously worked up in the laboratories at Müllerstrasse, Berlin-Wedding where formerly, in addition to 1000 clerical workers in the main offices, 200 research workers and 500 factory workers were employed. Present production of synthetic hormones is small and limited to material prepared on a laboratory scale. According to Dr. Clerc, this production is less than 0.5 kilograms per month for each of the hormones testosterone, progesterone and desoxycorticosterone.

Many of the records of the manufacturing processes of Schering A.G., were destroyed or have been otherwise dispersed. Consequently it is difficult to obtain copies of supplementary information or drawings of apparatus required to illustrate the information available.

Figure A.122: Commercial synthesis of a variety of steroid hormones [FIAT 996].



Synthetic Hormones from Cholesterol

a) Preparation of Cholesterol

The basic raw material for the manufacture of these products is cholesterol, obtained either from spinal cord or wool-grease:

1. From spinal cord.

The "skin" (neural sheath) is removed from the spinal cord and 1000 kilogram batches are extracted for five days with ethylene dichloride in a continuous extractor. The extract is evaporated to dryness, the oily residue centrifuged at 20 to 60°, and the crude cholesterol is crystallized from alcohol yielding about 40 kilograms per batch.

2. From wool-grease:

A batch of 100 kilograms of unsaponifiable wool-wax is melted with two atmospheres steam and forced by compressed air into 700 liters of methanol at 40°. The mixture is steamed for five minutes and stirred. It is then cooled to 42° and settled. After decanting 600 liters of clear methanol, the sludge is boiled up with 400 liters of fresh methanol, cooled to 42°, settled and decanted. The methanol extracts are united, concentrated to 500 cc., and cooled to 7 to 8°. The crude cholesterol precipitates as a yellow paste. It is centrifuged and dried yielding 40 kilograms of dry crude cholesterol.

Four such batches are united, melted by steam heat, and passed through a filter to a crystallizer held at 70° for two to three hours. The cholesterol crystallizes in its own oil and is centrifuged at 60 to 65°. The oils are again crystallized at 50 to 60° and again centrifuged. The united cholesterol crystals amount to 10 kilograms. Recrystallization of 60 kilograms of fatty cholesterol crystals from 300 liters of ethanol containing one percent of toluene and recrystallization of the 50 kilograms of spirit-moist crystals from 400 liters of toluene-ethanol and 500 grams of animal charcoal yield a cholesterol, m.p. 144-146°. The material is dried and 40 kilograms of the solvent free crystals is boiled up with 400 liters of dilute acetone (1 : 10). Crystallization yields six to seven kilograms of pure cholesterol, m.p. 148-149°, from 100 kilograms of wool-wax.

b) Testosterone from Dehydroandrosterone Acetate

Testosterone: The key intermediate for the preparation of

INTRODUCTION

Objective:

A visit was made to the Elberfeld plant of the I. G. Farbenindustrie A. G., to determine the processes used for preparation of a series of pharmaceuticals and pharmaceutical intermediates for which no information as to methods of manufacture was available.

Evaluation:

Processes were obtained for eleven pharmaceuticals and as many more underlying intermediates. These processes are of interest not only for themselves but because of special procedures used and certain reactions carried out which have general value as novel methods of chemical synthesis.

PRODUCTS AND PROCESSES

(For tabular list and process detail see Appendix 3)

Pardinon:

Pardinon or meta-fluor-thyrosin was first announced by publication of the chemical formula of the products in 1944. (Schw. Ap. Ztg. 82, 165, 1944). A process outline was drawn up by Dr. Medick in 1943 and this was followed by process detail dated 1946. (Briefly the synthesis of this product is carried out as follows: Cresidine (3-amino-4-cresol methyl ether) is diazotized and the diazoborofluoride is formed by reaction with hydroborofluoric acid. This product is decomposed to 3-fluoro-4-cresol methyl ether with evolution of nitrogen and release of boron trifluoride. On oxidation the compound goes over to fluoroanisaldehyde (3-fluoro-4-methoxybenzaldehyde). As a separate synthesis the hydrochloride of glycollic acid ethyl ester is condensed with potassium cyanate to form hydantoin acid ethyl ester. This product is ring closed to form hydantoin and then condensed with fluoroanisaldehyde to form a compound known as Fluantoin. By a series of reactions carried on successively in one reaction vessel saponification of the cresol ether takes place, the hydantoin ring is broken and the double bond of the carbon attached to the benzene ring is reduced. The product so obtained is the final product Pardinon.

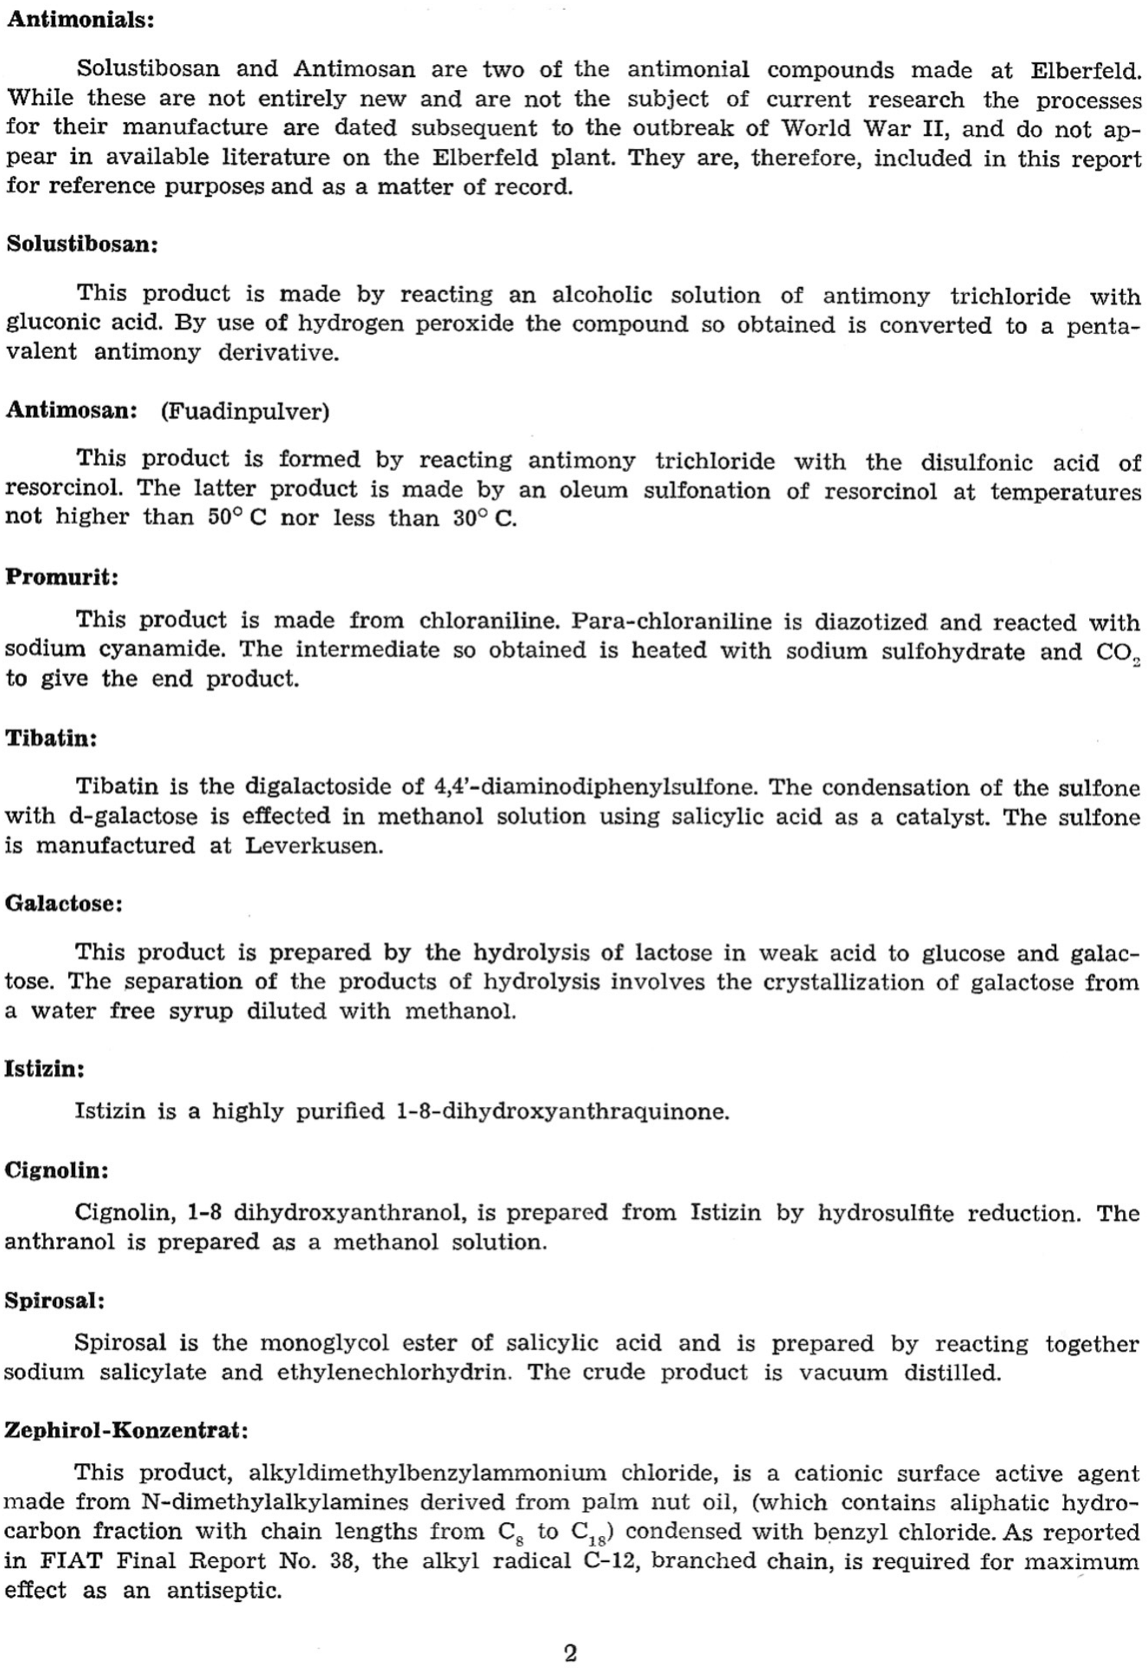
Yatrensäure:

Yatrensäure (7-iodo-8-hydroxyquinoline-5-sulfonic acid) for which the current process is dated March 1945, is derived from 8-hydroxyquinoline-5-sulfonic acid by iodination with sodium iodide-sodium iodate solution using hydrogen peroxide as the oxidizing agent. The intermediate hydroxyquinolinesulfonic acid is derived from 8-hydroxyquinoline by sulfonation of the latter with sulfuric acid monohydrate.

W - 941: This product (2-chlor-4-dimethyl-amino-6-methylpyrimidin), for which the current process is dated November 1944, is made by chlorination of Urazil (2,4 dihydroxy-6-methylpyrimidin) with phosphorous oxychloride, followed by reaction with dimethylamine replacing one chlorine atom with the dimethylamine group to give the final product.

Urazil is formed by reacting thiourea with ethylacetoacetate with subsequent treatment with chloracetic acid to form the dihydroxy product from the thiohydroxymethylpyrimidin formed in the first reaction.

Figure A.125: Commercial synthesis of a variety of pharmaceuticals [FIAT 1014].



Antimonials:

Solustibosan and Antimosan are two of the antimonial compounds made at Elberfeld. While these are not entirely new and are not the subject of current research the processes for their manufacture are dated subsequent to the outbreak of World War II, and do not appear in available literature on the Elberfeld plant. They are, therefore, included in this report for reference purposes and as a matter of record.

Solustibosan:

This product is made by reacting an alcoholic solution of antimony trichloride with gluconic acid. By use of hydrogen peroxide the compound so obtained is converted to a pentavalent antimony derivative.

Antimosan: (Fuadinpulver)

This product is formed by reacting antimony trichloride with the disulfonic acid of resorcinol. The latter product is made by an oleum sulfonation of resorcinol at temperatures not higher than 50° C nor less than 30° C.

Promurit:

This product is made from chloraniline. Para-chloraniline is diazotized and reacted with sodium cyanamide. The intermediate so obtained is heated with sodium sulfohydrate and CO_2 to give the end product.

Tibatin:

Tibatin is the digalactoside of 4,4'-diaminodiphenylsulfone. The condensation of the sulfone with d-galactose is effected in methanol solution using salicylic acid as a catalyst. The sulfone is manufactured at Leverkusen.

Galactose:

This product is prepared by the hydrolysis of lactose in weak acid to glucose and galactose. The separation of the products of hydrolysis involves the crystallization of galactose from a water free syrup diluted with methanol.

Istizin:

Istizin is a highly purified 1-8-dihydroxyanthraquinone.

Cignolin:

Cignolin, 1-8 dihydroxyanthranol, is prepared from Istizin by hydrosulfite reduction. The anthranol is prepared as a methanol solution.

Spirosal:

Spirosal is the monoglycol ester of salicylic acid and is prepared by reacting together sodium salicylate and ethylenechlorhydrin. The crude product is vacuum distilled.

Zephirol-Konzentrat:

This product, alkyldimethylbenzylammonium chloride, is a cationic surface active agent made from N-dimethylalkylamines derived from palm nut oil, (which contains aliphatic hydrocarbon fraction with chain lengths from C_8 to C_{18}) condensed with benzyl chloride. As reported in FIAT Final Report No. 38, the alkyl radical C-12, branched chain, is required for maximum effect as an antiseptic.

FIAT 1014. ***Miscellaneous Pharmaceuticals and Pharmaceutical Intermediates Manufactured at I. G. Farbenindustrie A. G., Elberfeld.*** [See pp. 2471–2472 for a summary. This is a very long report, mostly in German, on the commercial synthesis of various pharmaceuticals based on the work of Gerhard Domagk, Gerhard Schrader, and other top I.G. Farben biochemists. See also FIAT 1042.]

FIAT 1046. ***Production of Crude Citric Acid by Fermentation in Germany.***

Charging of the Fermentation Room:

Each fermentation room contains 80 pans supported on a steel framework. The treated molasses is run from the cooking tanks into the individual pans by means of rubber hose until a liquor depth of about eight centimeters is reached. After the pans are charged the contents are allowed to cool until the temperature reaches about 40^{o}C. At this point, spores of the mold, Aspergillus niger, which have been grown in Kolle bottles in the laboratory, are introduced into the air stream entering the room and blown over the surface of the pans.

Fermentation Cycle:

The spores germinate on the molasses solution and in about 48 hours the entire surface is covered by the mycelia of the mold. During the early growth phase the air temperature is maintained close to 30^{o}C and the air is slowly circulated. When the growth is established, the conversion of the sugar to citric acid takes place rapidly with the liberation of considerable heat. A large proportion of the heat is held as latent heat in the water vapor given off through the respiration of the mold. As a consequence the relative humidity in the room tends to increase, but this increase is held well below the saturation point by the constant introduction of low humidity fresh air from the air conditioning equipment. After seven days, the rate of fermentation decreases and by the tenth day the room contents are ready for harvesting. [...]

Clarification and Extraction:

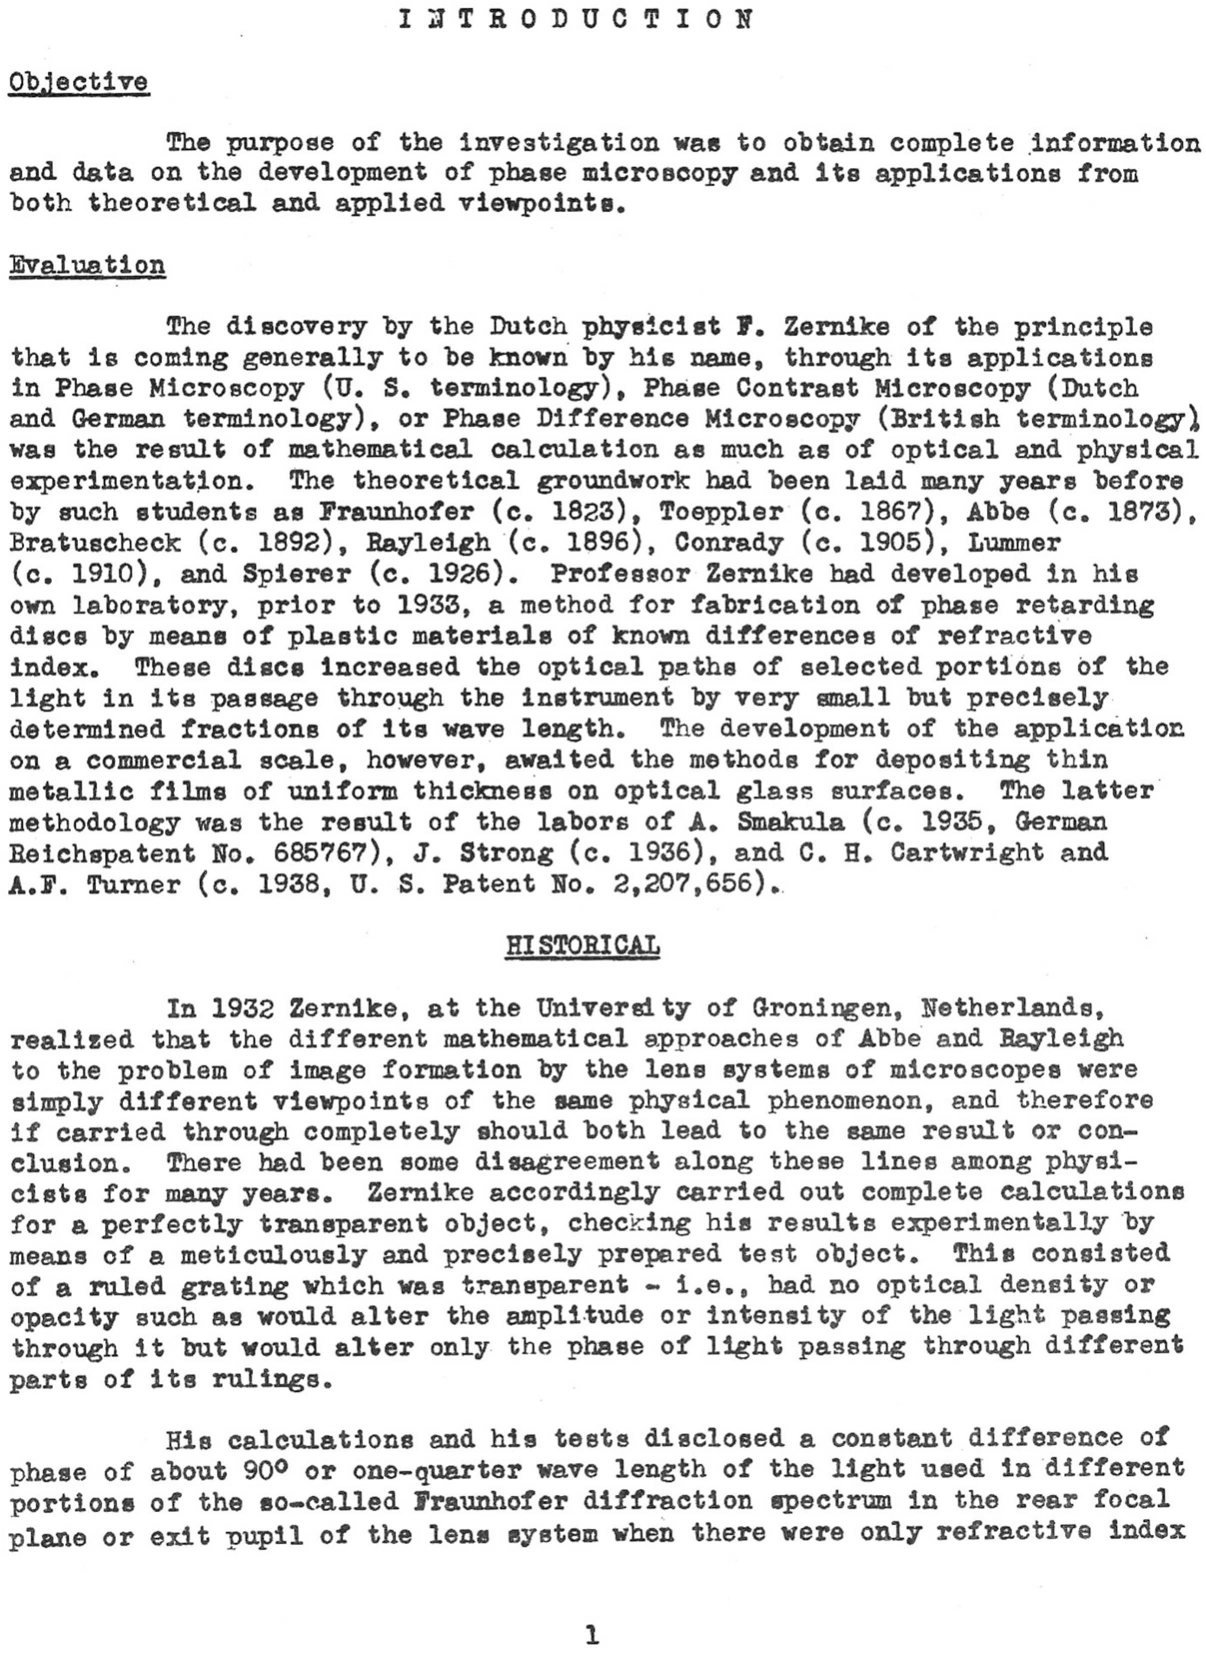
The fermented liquor is freed from insoluble material, which forms during the fermentation, by settling and decantation. The mycelia are dumped from the cars into tanks where the citric acid adhering to the wrinkled surfaces of the mold is extracted by counter-current washing. The extract joins the main body of the fermentation liquor.

Recovery of the Citric Acid:

The clarified fermentation liquor is sent to the precipitation tanks and heated to 90^{o}C. Slaked lime is added until pH 8.0 to 8.2 is reached. The tank contents are then brought to the boiling point. The mixture is stirred and the calcium citrate is quickly precipitated. The calcium citrate is separated by filtration, washed, dried and sacked.

The calcium citrate is converted to citric acid by a process of refining which is very similar to the manufacture of tartaric acid.

FIAT 1059. ***The Phase Principle in Microscopy.*** **With supplement.**
[See pp. 2474–2484 for some key pages from this long report documenting the invention, demonstration, and technology transfer of phase-contrast microscopy.]



INTRODUCTION

Objective

The purpose of the investigation was to obtain complete information and data on the development of phase microscopy and its applications from both theoretical and applied viewpoints.

Evaluation

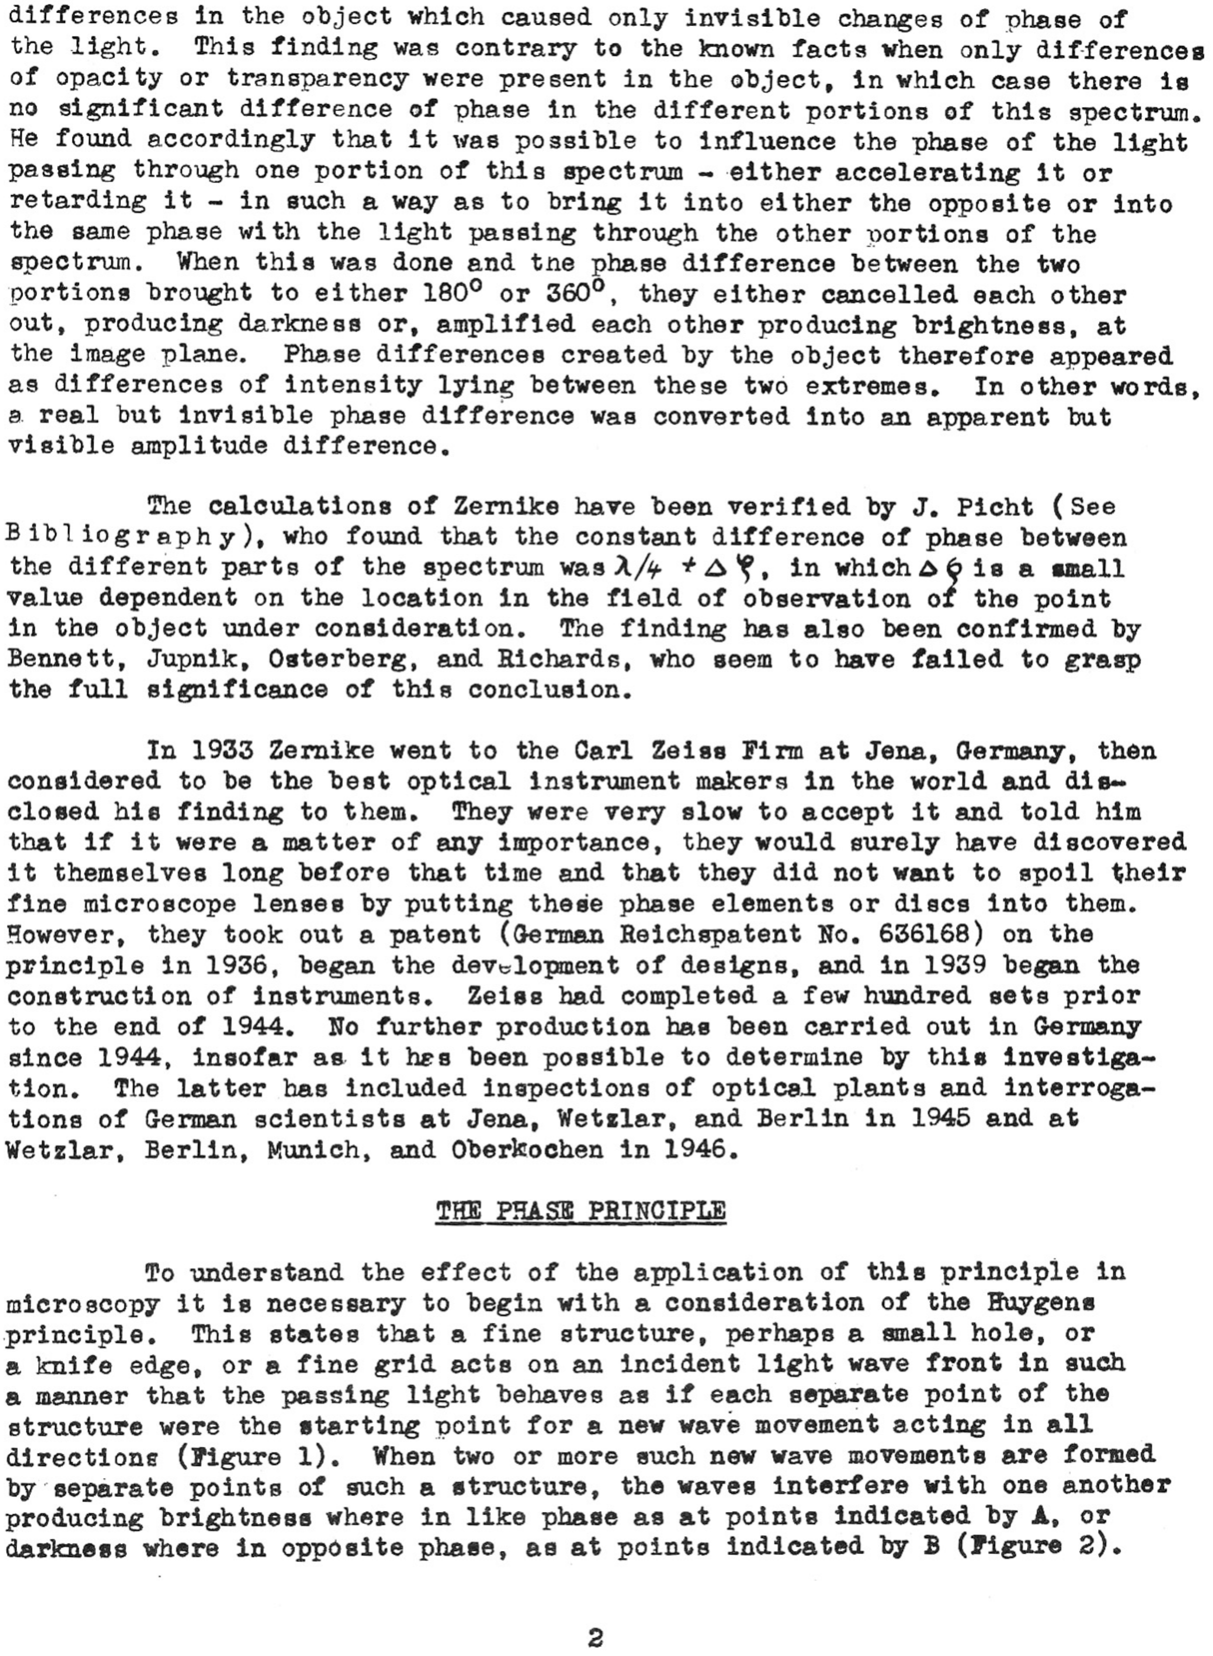
The discovery by the Dutch physicist F. Zernike of the principle that is coming generally to be known by his name, through its applications in Phase Microscopy (U. S. terminology), Phase Contrast Microscopy (Dutch and German terminology), or Phase Difference Microscopy (British terminology) was the result of mathematical calculation as much as of optical and physical experimentation. The theoretical groundwork had been laid many years before by such students as Fraunhofer (c. 1823), Toeppler (c. 1867), Abbe (c. 1873), Bratuscheck (c. 1892), Rayleigh (c. 1896), Conrady (c. 1905), Lummer (c. 1910), and Spierer (c. 1926). Professor Zernike had developed in his own laboratory, prior to 1933, a method for fabrication of phase retarding discs by means of plastic materials of known differences of refractive index. These discs increased the optical paths of selected portions of the light in its passage through the instrument by very small but precisely determined fractions of its wave length. The development of the application on a commercial scale, however, awaited the methods for depositing thin metallic films of uniform thickness on optical glass surfaces. The latter methodology was the result of the labors of A. Smakula (c. 1935, German Reichspatent No. 685767), J. Strong (c. 1936), and C. H. Cartwright and A.F. Turner (c. 1938, U. S. Patent No. 2,207,656).

HISTORICAL

In 1932 Zernike, at the University of Groningen, Netherlands, realized that the different mathematical approaches of Abbe and Rayleigh to the problem of image formation by the lens systems of microscopes were simply different viewpoints of the same physical phenomenon, and therefore if carried through completely should both lead to the same result or conclusion. There had been some disagreement along these lines among physicists for many years. Zernike accordingly carried out complete calculations for a perfectly transparent object, checking his results experimentally by means of a meticulously and precisely prepared test object. This consisted of a ruled grating which was transparent - i.e., had no optical density or opacity such as would alter the amplitude or intensity of the light passing through it but would alter only the phase of light passing through different parts of its rulings.

His calculations and his tests disclosed a constant difference of phase of about 90° or one-quarter wave length of the light used in different portions of the so-called Fraunhofer diffraction spectrum in the rear focal plane or exit pupil of the lens system when there were only refractive index

Figure A.127: Invention, demonstration, and technology transfer of phase-contrast microscopy [FIAT 1059].



differences in the object which caused only invisible changes of phase of the light. This finding was contrary to the known facts when only differences of opacity or transparency were present in the object, in which case there is no significant difference of phase in the different portions of this spectrum. He found accordingly that it was possible to influence the phase of the light passing through one portion of this spectrum - either accelerating it or retarding it - in such a way as to bring it into either the opposite or into the same phase with the light passing through the other portions of the spectrum. When this was done and the phase difference between the two portions brought to either 180° or 360°, they either cancelled each other out, producing darkness or, amplified each other producing brightness, at the image plane. Phase differences created by the object therefore appeared as differences of intensity lying between these two extremes. In other words, a real but invisible phase difference was converted into an apparent but visible amplitude difference.

The calculations of Zernike have been verified by J. Picht (See Bibliography), who found that the constant difference of phase between the different parts of the spectrum was $\lambda/4 + \Delta\varphi$, in which $\Delta\varphi$ is a small value dependent on the location in the field of observation of the point in the object under consideration. The finding has also been confirmed by Bennett, Jupnik, Osterberg, and Richards, who seem to have failed to grasp the full significance of this conclusion.

In 1933 Zernike went to the Carl Zeiss Firm at Jena, Germany, then considered to be the best optical instrument makers in the world and disclosed his finding to them. They were very slow to accept it and told him that if it were a matter of any importance, they would surely have discovered it themselves long before that time and that they did not want to spoil their fine microscope lenses by putting these phase elements or discs into them. However, they took out a patent (German Reichspatent No. 636168) on the principle in 1936, began the development of designs, and in 1939 began the construction of instruments. Zeiss had completed a few hundred sets prior to the end of 1944. No further production has been carried out in Germany since 1944, insofar as it has been possible to determine by this investigation. The latter has included inspections of optical plants and interrogations of German scientists at Jena, Wetzlar, and Berlin in 1945 and at Wetzlar, Berlin, Munich, and Oberkochen in 1946.

THE PHASE PRINCIPLE

To understand the effect of the application of this principle in microscopy it is necessary to begin with a consideration of the Huygens principle. This states that a fine structure, perhaps a small hole, or a knife edge, or a fine grid acts on an incident light wave front in such a manner that the passing light behaves as if each separate point of the structure were the starting point for a new wave movement acting in all directions (Figure 1). When two or more such new wave movements are formed by separate points of such a structure, the waves interfere with one another producing brightness where in like phase as at points indicated by A, or darkness where in opposite phase, as at points indicated by B (Figure 2).

APPENDIX 6

BIOGRAPHICAL SKETCH OF F. ZERNIKE.

The following is a brief biographical sketch of the discoverer of the phase principle in optics.

Fritz Zernike was born 16 July 1888 at Amsterdam, Netherlands. His father was C.F.A. Zernike. His mother's maiden name was Dieperink. Address: v Ketwich-Verschuurlan 5, Groningen, Netherlands. He received his education at the University of Amsterdam, taking his Bachelor's degree in chemistry in 1905, his Doctor's examination in 1912. His Ph.D. degree in physics was awarded in 1915. His thesis was on critical opalescence theory and experiments, for which he was also awarded the Gold Medal of the Holland Society of Sciences in Haarlem.

He married Dora van Bommel van Vloten in 1919, who died during the liberation of the Netherlands in 1945. There are two children, Wout, born in 1925 and Fritz, born in 1930.

He began his professional career as Assistant in Astronomy in 1913, was appointed Lecturer in Theoretical Physics, University of Groningen in 1915, and Professor in 1920, which position he still holds. He is a member of the Royal Netherlands Academy of Sciences and has listed his hobbies as statistics, optics, and instrument design.

His mathematical interest has always been keen, and he has shown a faculty of combining theory with experiment. That is his outstanding characteristic. His paper on "Theory of Probability," published in the German Handbuch der Physik in 1928, is considered in Holland as a classic among modern probability theories. He worked with the great astronomer Kapteyn and later collaborated with the physicist Ornstein. One of his observations on opalescence in the immediate neighborhood of the critical point became the starting point of Ornstein and Zernike's work on the "swarm" theory, which was later successfully applied to the theory of liquids. Ornstein and Zernike also carried out researches, on the solid state and on a possible metastability in the hydrogen spectrum.

Most of his theoretical problems have led, by his own hands, to experimental and technical devices. Best known of these are the Zernike Galvanometer, improvements in infra-red and ultra-violet spectroscopy with thermopile and photographic plate, and improvements in the construction of the electromagnet.

47

INTRODUCTION

Objective

The investigation was undertaken for the purpose of obtaining descriptions of the new designs of phase contrast microscope accessories expected to be produced in Germany under German patent DRP 636168, at Zeiss Opton, Oberkochen, Kreis Aalen, Württemberg, (U.S. Zone Württemberg - Baden), as well as of the "Time-Lapse" apparatus for the production of motion picture films of growth and disease processes in living specimens.

Evaluation

The Zeiss Firm were the only optical instrument makers to produce phase microscopes on a commercial scale prior to 1946. The designs described in this report represent improvements over the original designs completed by Zeiss and placed in production at Jena, Germany, in 1942.

HISTORICAL

A program for production of medico-optical instruments, supplies, accessories, and equipment needed for the public health and internal economy of Germany was initiated on rented premises at Oberkochen, Kreis Aalen, Württemberg, by former employees and scientific associates of the Carl Zeiss Firm resident in U.S. Zone of Germany under authority granted by the local German Government, Landeswirtschaftsamt, Stuttgart, and control of the U.S. Military Government for Germany in June 1946. This enterprise was incorporated as Zeiss Opton by the Amstgericht Court at Heidenheim, with limited liability and declared capital of 1,000,000 Rm. in October 1946. The articles of incorporation were confirmed by the Ministry for Trade and Industry, Wirtschaftsministerium, Stuttgart, under date of 4 January, 1947.

A high priority in the development program was assigned in September 1946 to phase microscope accessories on account of their importance to biological and medical research, public health, and as items for export, since prior to 1946 these items had been produced on a commercial basis nowhere else in the world except in Germany.

GENERAL

The production of an image based on differences of refraction by different portions of transparent microscopic objects through application of the Zernike phase principle, making possible the observation and study of such objects in un-fixed, unstained, and living condition, requires incorporation or insertion into the optical system of the microscope, and adjustment with relationship to one another, of three principal sets of light phase controlling accessories:

(a) An annular slit source of light, of such shape and dimensions that the full apertures of the microscope condenser and objective lens systems are not completely illuminated thereby, which must be so adjusted that its image

TEST AND CONTROL PROCEDURES

The thickness of the metal film deposited on the glass surface by vaporization in vacuo, after stabilization of the vacuum, is determined by the quantity of the metal vaporized and the distance of the surface from the vaporization crucible. Test surfaces are coated by a series of different quantity/distance combinations, the absorption/transmission ratios obtained determined photometrically, and the technique then standardized at the ratio found to yield the desired result. To standardize the phase refraction/retardation characteristic, a series of rings are fabricated by different cryolite vaporization quantity/distance techniques, and mounted by means of the cement to be used between thin, optically flat, glass discs. The refractive indices of the cryolite film and of the cement being known, and the thickness between glasses known and controllable, the retardation of the secondary spectral areas can be determined to within approximately 0.1 lambda by calculation from the general formula. These test series phase plates are then inserted at the rear focal plane above the last glass surface of a low power microscope objective. It may then be used by a competent biologist to examine freshly prepared test objects, epithelia, blood cells, insect chromosomes, etc., with which he is thoroughly familiar.

OCULAR CENTERING DEVICE

The auxiliary magnifying eyepiece, required for easy and accurate centering of the condenser phase diaphragm in registration with the "Z disc" of the objective (shown in Figure 4) is essentially a simple microscope, consisting of a four element 25 X compensating ocular (1), and an objective lens (3). The focal length of the ocular is 10 millimeters; of the objective 57 millimeters. These lenses are mounted in telescoping metal tubes (4) and (5), focusable from infinity to about 150 millimeters. The objective tube is fitted with a diaphragm (2) and shoulder (4), and is of the same outside diameter as the microscope ocular used in the standard microscope ocular tube.

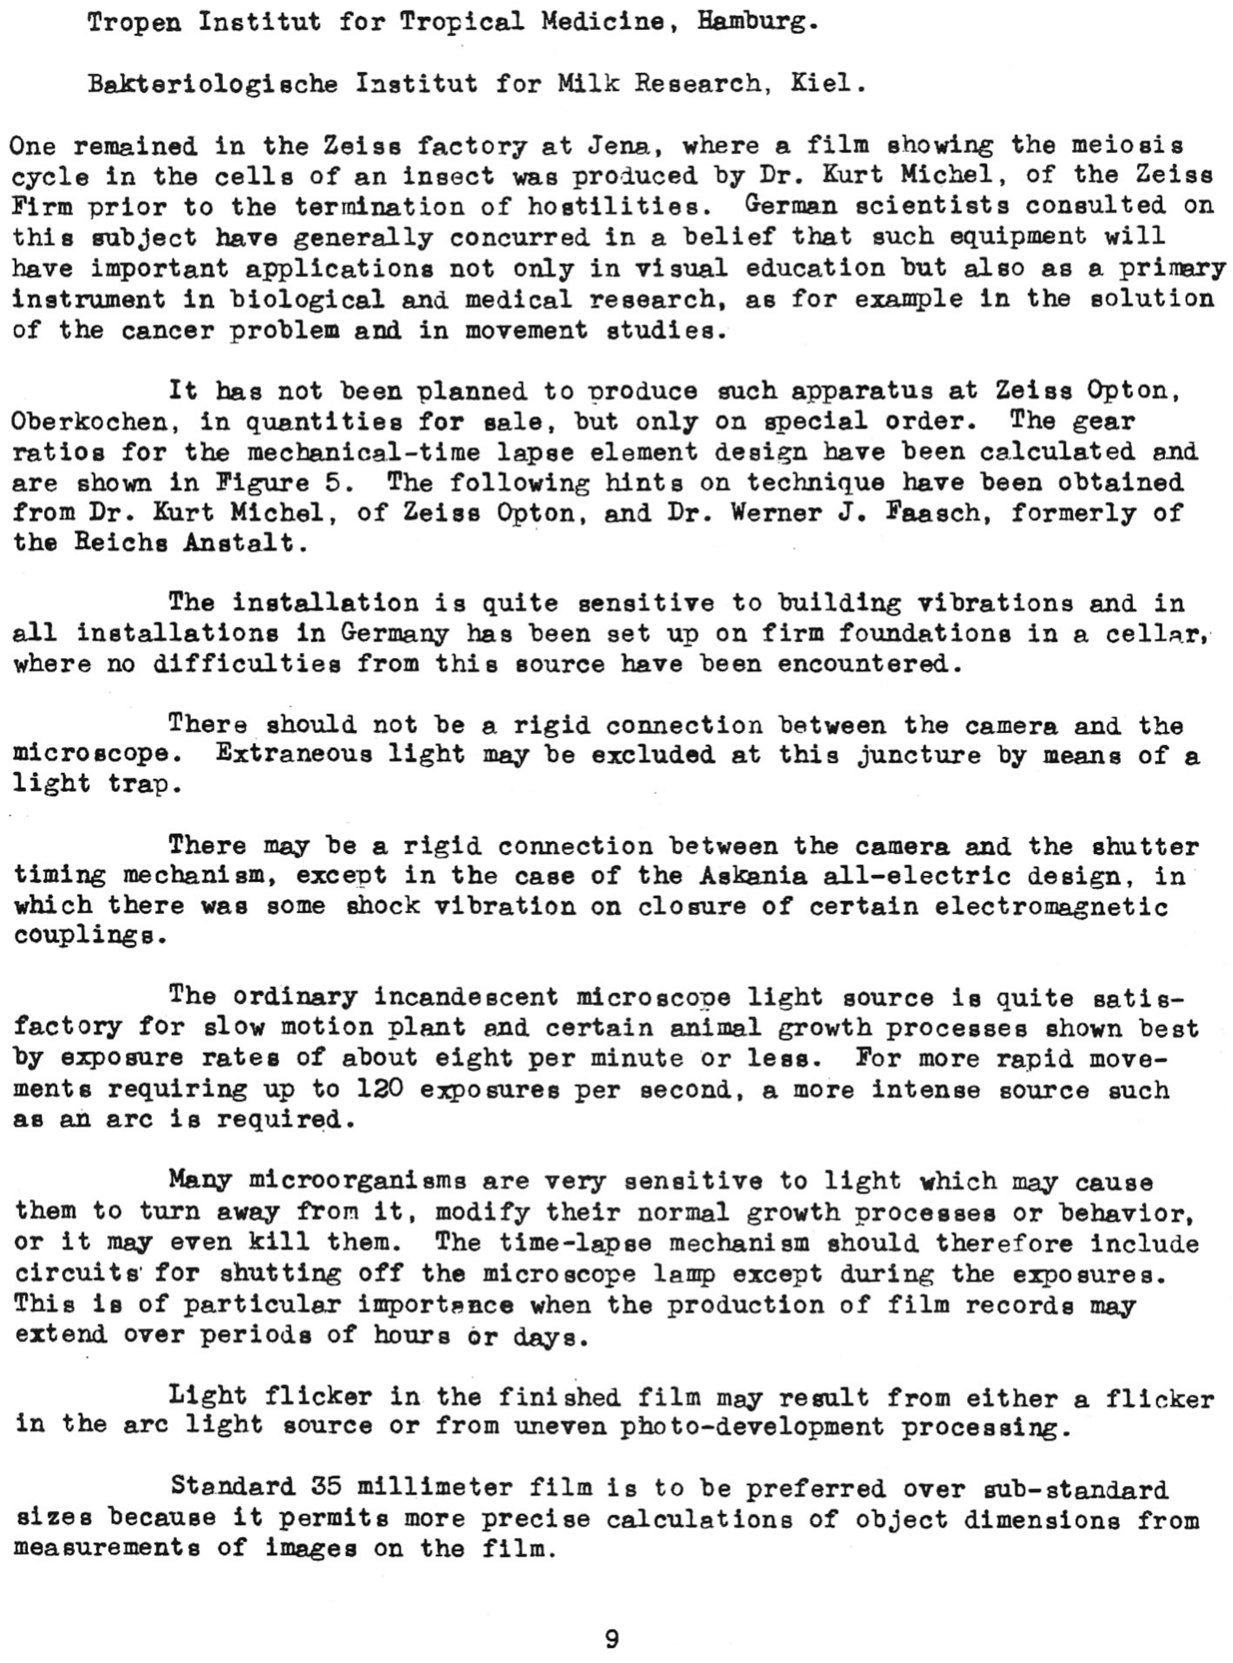
THE "TIME-LAPSE" TECHNIQUE FOR PRODUCTION OF MOTION PICTURE FILMS

The competency of the phase microscope to make visible unfixed and unstained living structures, as well as advances in visual education methods, which have been made in recent years, have added emphasis to the need for adequate apparatus for the production of motion picture films by means of microcinephotography. The trend toward visual education was early recognized in Germany, where the government set up an agency to promote such methods. Subsequent to the development of phase microscope accessories in 1940, the Carl Zeiss Firm at Jena fabricated five complete sets of apparatus, including the phase microscope, 35 millimeter camera, arc and incandescent light source, interval timer or time-lapse mechanism, and work table. These were sold for 10,000 Rm. and were distributed to the following institutions:

Reichs Anstalt für Film und Bild in Wissenschaft und Unterricht
(Government Agency for Visual Education), 12 Kleist Str., Berlin.

I. G. Farbenindustrie, A.G., Frankfurt-Höchst Laboratories.

Figure A.135: Invention, demonstration, and technology transfer of phase-contrast microscopy [FIAT 1059 Supplement].



Tropen Institut for Tropical Medicine, Hamburg.

Bakteriologische Institut for Milk Research, Kiel.

One remained in the Zeiss factory at Jena, where a film showing the meiosis cycle in the cells of an insect was produced by Dr. Kurt Michel, of the Zeiss Firm prior to the termination of hostilities. German scientists consulted on this subject have generally concurred in a belief that such equipment will have important applications not only in visual education but also as a primary instrument in biological and medical research, as for example in the solution of the cancer problem and in movement studies.

It has not been planned to produce such apparatus at Zeiss Opton, Oberkochen, in quantities for sale, but only on special order. The gear ratios for the mechanical-time lapse element design have been calculated and are shown in Figure 5. The following hints on technique have been obtained from Dr. Kurt Michel, of Zeiss Opton, and Dr. Werner J. Faasch, formerly of the Reichs Anstalt.

The installation is quite sensitive to building vibrations and in all installations in Germany has been set up on firm foundations in a cellar, where no difficulties from this source have been encountered.

There should not be a rigid connection between the camera and the microscope. Extraneous light may be excluded at this juncture by means of a light trap.

There may be a rigid connection between the camera and the shutter timing mechanism, except in the case of the Askania all-electric design, in which there was some shock vibration on closure of certain electromagnetic couplings.

The ordinary incandescent microscope light source is quite satisfactory for slow motion plant and certain animal growth processes shown best by exposure rates of about eight per minute or less. For more rapid movements requiring up to 120 exposures per second, a more intense source such as an arc is required.

Many microorganisms are very sensitive to light which may cause them to turn away from it, modify their normal growth processes or behavior, or it may even kill them. The time-lapse mechanism should therefore include circuits for shutting off the microscope lamp except during the exposures. This is of particular importance when the production of film records may extend over periods of hours or days.

Light flicker in the finished film may result from either a flicker in the arc light source or from uneven photo-development processing.

Standard 35 millimeter film is to be preferred over sub-standard sizes because it permits more precise calculations of object dimensions from measurements of images on the film.

A.2 Prostheses and Neural Interfaces (Bionics)

[Due to the combination of strong support for scientific innovation and the large numbers of people with war injuries, the German-speaking world led the development of prosthetic limbs. The development of prostheses also overlapped with the development of methods for interfacing electrical or electromechanical systems with the human nervous system.

In 1808, Albrecht Ludwig Berblinger (German states, 1770–1829) developed the first prosthetic legs with movable joints, which made the legs much more practical to use. See p. 398. (Berblinger also made early attempts at developing manned gliders.)

Jakob Riedinger (German, 1861–1917) developed a prosthetic arm with movable joints, the "Würzburg working arm." See p. 399. He also established national programs to treat and to assist the disabled.

During World War I, Ferdinand Sauerbruch (German, 1875–1951) invented the first prosthetic arms that could be controlled by residual arm stump muscles, a design that became known as the "Sauerbruch arm." See p. 399. In 1904, Sauerbruch also invented a pressurized chamber (the "Sauerbruch chamber") for much more safely opening the thorax of a patient to conduct operations on the heart or lungs.

Georg Schlesinger (German, 1874–1949) worked with Jakob Riedinger and Ferdinand Sauerbruch to design and build improved prosthetic arms and legs during and after World War I. See p. 399. Schlesinger also spent much of his career improving the standardization, testing, and calibration of machine tools.

From the nineteenth century onward, numerous scientists from the German-speaking world experimented with electrodes to carry signals to or from the brains of animals or humans (pp. 232 ff). Those scientists included Gustav Fritsch (German, 1838–1927), Eduard Hitzig (German, 1838–1907), Jacques Loeb (German, 1859–1924), Oskar Vogt (German, 1870–1959), Cécile Vogt-Mugnier (French but worked in Germany, 1875–1962), and Walter Rudolf Hess (Swiss, 1881–1973).

In 1924, Hans Berger (German, 1873–1941) invented electroencephalography (EEG), the method of detecting, measuring, and recording human brain waves. Napoleon Cybulski (Polish, 1854–1919) and Adolf Beck (Polish/Austrian, 1863–1942) also carried out early experiments in electroencephalography. See p. 259.

During and after World War II, Ulrich Henschke (German, 1914–1980) and Hans Mauch (German, 1906–1984) further advanced those two lines of research—prostheses and electrical interfaces with the human nervous system. They also combined those two areas of research by trying to develop prosthetic limbs or prosthetic sensory systems that could interface with the human nervous system, creating a new field that later became known as "bionics." (The term bionics was coined in 1958 at the U.S. Air Force laboratory where Henschke and Mauch worked—see p. 2493—and was subsequently popularized by Martin Caidin's 1972 novel *Cyborg* and the 1970s television series based on it, *The Six Million Dollar Man* and *The Bionic Woman*).

Also during the war, Ulrich Henschke and Hans Mauch headed an aviation medicine research institute that aimed to improve the efficiency of human-operated weapons systems. [There are brief mentions of Henschke and Mauch and a group photo in Campbell and Harsch 2013.] It appears that they explored neural interfaces for those applications as well, since such interfaces could improve the response times for pilots and weapons operators and give them an advantage over their opponents who had to physically move controls with their hands and feet, or help pilots respond more rapidly in controlling high-speed jets, rocket planes, or rockets.

As an example of how pilot response times were considered a major factor and a research priority at the highest levels, Heinrich Himmler's adjutant, Werner Grothmann, reported that Himmler had concerns about piloted long-range rockets (p. 5359):

> Either someone pilots the rocket into the target, or it must go fully automatic. Himmler was skeptical as to whether a pilot could react at that speed. I mean, the rocket was supposed to fly several thousand kilometers.

(For fictional examples of how a neural interface system might be advantageous for a pilot's reaction times, see the 1977 Craig Thomas novel *Firefox* and its 1982 film adaptation.)

Some of the more advanced work of Henschke and Mauch was mentioned in the documents quoted in this section, but detailed reports by Henschke and Mauch or detailed reports by others assessing that work have never been publicly released. Can those reports be located in archives and declassified? Just how far did their work progress, both during and after the war? What direct or indirect effects did it have on later work in this field?

Categories of users that were or likely would have been considered for the neural interface work would have included:

- Handicapped or injured people (pp. 2488–2491).
- Pilots of manned airplanes, jets, rocket planes, and rockets (pp. 2488, 2492, 2506–2508, 2513).
- Operators of remotely guided missiles or other weapons systems (pp. 2488, 2492, 2506–2508, 2513) [NavTecMisEu 229-45].
- Operators of teleoperated robots (Section 6.7.4).

Interface methods that were or likely would have been considered for the neural interface work would have included:

- Signals in peripheral nerves (pp. 239–243, 336, 2488–2491).
- Brain waves or other signals in the central nervous system (pp. 259, 2489).
- Eye motions (pp. 2506–2508).

Interfaced devices that were or likely would have been considered would have included:

- Prosthetic legs (pp. 2488–2491).
- Prosthetic arms (pp. 2488–2491).
- Visual prostheses (pp. 2488–2489, 2491, 2509–2513).
- Aircraft or other vehicle controls (pp. 2492, 2506–2508, 2513).
- Remotely guided missiles or other weapons system controls (pp. 2492, 2506–2508, 2513) [NavTecMisEu 229-45].

Other work by Henschke and Mauch was better documented in publicly available sources:

- Henschke and Mauch developed what ultimately became known as the Swing-aNd-Stance (S-N-S) hydraulically controlled prosthetic leg, which has been used worldwide for decades since then. See pp. 2494–2504 and 2509–2513.
- Henschke and Mauch developed and patented a tachistoscope that could present high-speed visual information to a user and monitor the person's reactions (pp. 2506–2508). It seems likely that the tachistoscope was part of a larger program to test and improve the reaction times of pilots and weapons systems operators using neural interfaces as compared to manual controls.
- During the war, Henschke also developed simulators for training operators of remotely guided missiles [NavTecMisEu 229-45].
- Henschke and Mauch designed a variety of aviation control systems (pp. 2492, 2513).
- Henschke developed brachytherapy methods for treating cancer (p. 2514).
- Mauch played a key role in the early development of jet engines and jet aircraft (p. 1764).
- Mauch designed space suits (p. 2513).
- Henschke and Mauch conducted other work in aviation medicine (pp. 2488–2489, 2513) [Campbell and Harsch 2013].

Was similar work on neural interfaces for prostheses and/or weapons systems conducted by other German-speaking scientists? It seems likely, since the German-speaking world pioneered the relevant fields, and there would have been strong demand for such applications.

Much more archival research needs to be conducted in order to investigate the hypotheses I have outlined above and to elucidate the true and complete history of German-speaking work in these areas.]

Charles A. Lindbergh. 1970. *The Wartime Journals of Charles A. Lindbergh.* New York: Harcourt Brace Jovanovich. pp. 977–978.

From Oberammergau Lieutenant Uellendahl and I drove to Garmisch-Partenkirchen to see the Medical Research Institute operated by Dr. [Ulrich] Henschke, located on the slope of a mountain—a small institute, simply built and simply but very intelligently run. Dr. Henschke, a man in his mid thirties, turned out to be a great admirer of Dr. Carrel—had studied *Man the Unknown* with care and understood it as no one else I have talked to. He had a copy of *The Culture of Organs* on his shelves, and the Swiss edition of *Listen! the Wind*. He says his greatest ambition is to have an institute such as Carrel wrote of.

We discuss a number of Dr. Henschke's projects: gunnery sights, artificial limbs, hearing for the blind, cellular emanations, etc. He shows us through his laboratories—small buildings like mountain cabins—views of Alps and valleys through the windows—ideal places for creative work. In one he is testing new methods of controlling guns in aircraft. "It is best to use only one group of muscles." He has a stick (pilot's) with a bar on top which acts as a rudder, "so it is not necessary to use the feet at all in aiming a fighter." I protest, saying that I think we are getting too far away from monkeys anyhow, and that I do not see why we should not also use our feet. He asks me to try it out for myself—a rather crude affair made quickly out of plank and wire. I get down in the seat while the apparatus is adjusted.

At one end of the room is a rotating stick, at the end of which a photoelectric cell is fastened. A spotlight is fastened to the stick, and one is supposed to keep the light beam on the photoelectric cell. As long as the beam covers half or more of the cell, a counter, set to the rate of fire of a machine gun, is in operation. When the beam covers less than half the cell, the counter stops operating. By means of a stop watch the number of hits per minute are counted.

I found that I made a much better score when using the stick alone, which I have never done before, than when the spotlight was hooked up to the rudder and stick as in a normal fighter. The difference was several hundred per cent in favor of the former method! However, in fairness, it must be said that the rudder hookup was cramped and jerky. But this is not enough to account for the great difference in the number of hits I made. I tried removing my heavy G.I. boots and doubled my previous score with the conventional controls—one has a much better "feel" with his shoes off. But the advantage of controlling everything with the arms, "one group of muscles alone," was still apparently great.

At another small building Dr. Henschke showed us where he was developing artificial limbs which would be actuated by the nerves and muscles of the stump. He demonstrated with two German soldiers, one of whom had lost an arm and the other a leg.

Joyce Milton. 1993. *Loss of Eden: A Biography of Charles and Anne Morrow Lindbergh.* New York: HarperCollins. pp. 415–416.

Charles worked for United Aircraft in Connecticut until May of 1945, and shortly after V-E day, he joined a Naval Technical Mission in Europe as a civilian representative of the corporation. [...]

Joining the Technical Mission in Munich, Lindbergh became part of a team of observers who drove their jeeps into territory where the Wehrmacht, defeated but not yet demobilized, was still in effective control. [...] Lindbergh's group located Professor Willy Messerschmitt, who was living in a barn; Dr. Felix Kracht, the inventor of the rocket glider; Dr. Helmut Schelp, assistant head of development of the jet and rocket propulsion program; Dr. Franz Josef Neugebauer, who was working on a design for a nuclear-propelled aircraft; Dr. August Lichte, a developer of the Junker JU 004 turbojet engine; and Dr. Ulrich Henschke, who was working on artificial limbs capable of being controlled by neurological impulses.

CIOS ER 97. *Luftfahrt-Forschungsanstalt München Medizinisches Institut Garmisch-Partenkirchen.* 14 June 1945. [This report is filled with spelling, capitalization, and grammatical errors that have been silently corrected here to make it more readable. The Germans who carried out this scientific work were conducting research decades ahead of their time. The Americans who reported on this scientific work could not even spell.]

In 1942 a "Research Order" was given to Dr. U. Henschke to form a new Aviation Medical Research Institute. It worked at first in connection with the Radiology Institute of the University of Berlin, and in June 1943 it was designated as an aeronautical research institute of Munich and called "Work-group Henschke." It was evacuated in 1944 to Garmisch-Partenkirchen to devote full time to aviation medicine. The institute now has departments in all major branches of aviation medicine, but some department heads were away to their respective universities and private homes at the time of German collapse and have been unable to return. The following research problems are among those on which the institute had been working with a brief summary of the type of work: [...]

J. Research on Prostheses.

For the past few months this institute had devoted most of its time to work on "eye prostheses" and extremity prostheses. Briefly, apparatuses have been constructed using selenium cells and photoelectric cells which convert visual stimuli into auditory sense. In the problem of limb prostheses the approach has been that of using the impulses of the amputated nerve to direct electro-mechanical prostheses which will be controlled mentally. This problem is in the beginning stages but work on it is going on at present. Beginning work on measurement of brain waves with apparatus capable of focusing on certain parts of the brain has also started.

Germans Tried to Develop Controlled Artificial Leg. *St. Joseph Gazette* (St. Joseph, Missouri), 19 September 1946, p. 7 [https://news.google.com/newspapers?id=zypaAAAAIBAJ&sjid=HkwNAAAAIBAJ&hl=es&pg=1168%2C1131947].

WRIGHT FIELD, Ohio, Sept. 18.—(INS)—An American intelligence team was reported tonight to have learned that German scientists experimented during the war on an artificial leg activated by impulses from the human brain.

According to information gained by an air materiel command technical intelligence team, the leg used electro-mechanical devices wired to the severed nerve endings.

Tonight's announcement from the Wright Field public relations office added:

"The Germans believed that galvanic electricity flowing along the nerves would supply the power impulses and that these could be controlled mentally, manipulating the leg according to the wishes of the wearer.

"Investigators believe that varying degrees of concentration were to be employed by the amputee on the theory that mental intensity would act like a rheostat, controlling the amount of nervous electricity and moving the leg in the manner desired. The Germans were as much interested in proving the disputed point of the existence of nervous electricity as they were in perfecting a fool-proof artificial leg.

Moved to Mountain Haven

"Originally located in Munich, the Aeronautical Research Institute was moved in August, 1944 to Garmisch-Partenkirchen, a mountain retreat where each scientist was given a combined house and laboratory of his own.

"These units were located 300 feet apart so that the occupants could work undisturbed. The mountain site was selected because its beauty lent itself to new ideas." Physicians, technicians, physicists, chemists, and psychologists were employed there. The institute was supported principally by the University of Munich and the German air force.

"While the electrical leg was still in the experimental stage when the war ended, the institute had completed work on an artificial limb, considered superior to any prosthetic device previously used. This was a hydraulic leg depending on a hand-operated valve and a piston-like arrangement in the calf.

Knee Controlled by Valve

"This artificial limb owes its success largely to the valve controlling the knee action. For standing, walking, or ascending and descending inclines, the knee joint must be maintained at various angles. The hydraulic system used in this leg does this with the voluntary control valve.

"A slight pull at the valve allows a slow knee flexion. A medium pull provides knee fixation, and a strong pull permits its extension. The last is essential in climbing stairs or inclines and makes it possible for the amputee to do this in a natural manner.

"Another interesting institute development was an artificial arm in which the hand was moved by a magnet and controlled by the stump muscles. Magnets also were used in another type of knee which was controlled in the same manner."

Ambitious Experiment: Brain-Controlled Artificial Leg was Goal of Nazi Scientists. *Press and Sun-Bulletin* (Binghamton, New York), 19 September 1946, p. 1.

When V-E Day ended their work, German scientists were attempting to perfect an artificial leg that could be controlled by impulses from the human brain. [...]

The scientists had also developed an artificial arm moved by magnets, and photo-electric and selenium cells to convert visual stimuli into auditory channels for the blind.

Ulrich K. Henschke and Hans A. Mauch. How Man Controls. In: Strughold, Hubertus, ed. 1950. *German Aviation Medicine, World War II.* 2 vols. Washington, D.C.: U.S. Government Printing Office. Vol. 1, pp. 83–91.

Starting from the need for better adaptation of aircraft controls to man, a new field of aviation medicine, the study of human control, was established.

The best approach was found to be the investigation and description of the behavior of man, while he controls, by the same experimental and mathematical methods as are used in regulator mechanics.

From this viewpoint, the following was found concerning the behavior of man in control cycles:

1. The transition function of man in simple control cycles corresponds in principle to that of an astatic transmission system with a delay time of about 0.2 second. It resembles in some respects the transition function of a so-called sampling transmission system operating in a stepwise manner.

2. In other control cycles with more complicated mechanical elements, man can perform other transition functions. The process of learning how to control can be interpreted by saying that man tends toward a transition function which is best adapted to the other parts of the control cycle.

3. Optimal regulation by man is reached, if the other parts of the regulation cycle are designed to make possible working of man with the same transition function as in simple control cycles consisting of a man as regulator and of a lever system as regulation section.

4. The use of man in control cycles is more desirable than that of an automatic regulator only if determination of the measuring value by the human eye and by the human brain takes an essential part in the regulation process.

R. R. Roth. 1983. The Foundation of Bionics. *Perspectives in Biology and Medicine* 26:2:229–242 [https://muse.jhu.edu/article/403622/pdf].

The word "bionics," as it appears today, originated with Maj. (later Col.) Jack E. Steele of the Aerospace Division of the U.S. Air Force, from the Greek word for life and suffix "ic," meaning "having the nature of". According to Steele, he coined the term in August 1958 to promote bionics as a new science. The research program, which was to receive the name "bionics" in the spring of 1959, was inaugurated at the Wright-Patterson Center of the U.S. Air Force. Bionics was under discussion, for the first time, at the Twelfth Annual Aeronautical Electronics Conference, held in May 1960. One session of the meeting, under the chairmanship of Dr. John E. Keto of the U.S. Air Force, was devoted to bionics. Four papers on bionics were read, including one by Major Steele. They were published in August 1960 in *Waveguide, Dayton Section of the Institute of Radio Engineers*. However, the official launching of the new science took place in September 1960 when 700 engineers, physicists, mathematicians, psychologists, psychiatrists, biologists, and biophysicists were invited to a congress in Dayton, Ohio. About 30 participants spoke about bionics, and a 500-page volume provides the record of the occasion.

[It is probably not a coincidence that the field of bionics was named and publicly inaugurated at the Air Force labs at Wright Patterson where Henschke and Mauch worked or had worked. Could future archival researchers investigate the possible connections between the work of Henschke and Mauch beginning there in 1946 and the public launch of the bionics program in the late 1950s?]

***Report from Heidelberg: The Story of the Army Air Forces Aero Medical Center in Germany 1945–1947.* 28 February 1947 [http://resource.nlm.nih.gov/14130150R].**

Though of no immediate aero medical significance, one of the most interesting and valuable contributions made by scientists working at the Aero Medical Center was the development of an artificial leg with a hydraulic knee joint which could be controlled by the wearer [p. 2499]. This new type of leg prosthesis, which was devised by Dr. Ulrich Henschke and Ing. Hans Mauch, was turned over by the Air Surgeon, in the summer of 1946, to the Surgeon General for further development and refinement in the United States. A 30-minute sound motion picture entitled "New Principles in Lower Extremity Prosthesis" was produced in Heidelberg by the 8th Combat Crew Camera Unit under the supervision of Major Sebon R. Wallace, former professor of psychology at Tulane University. This movie was presented to leading AAF flight surgeons at a conference in the Pentagon Building in May 1946, and thereafter was made available to the Surgeon General. The hydraulic type of artificial leg developed at the Aero Medical Center attracted considerable attention in the U.S. press [p. 2500] and also was the subject of an article by General Grow in the AAF Review [p. 2504].

June 28, 1946

The Air Surgeon announces the development of a hydraulic artificial leg at the Army Air Forces Aero Medical Laboratory in Heidelberg, Germany. Two German scientists, Ulrich K. Henschke and Hans A. Mauch, working in this Laboratory, have invented a device consisting of a small cylinder filled with hydraulic fluid and a piston connected with the upper leg. The movement of the piston is controlled by a be opened or closed at will with the ingenious belt.

'Hydraulic' Leg Being Tested by U. S. Doctors in Germany for Amputees

Before deciding to publish the following article, PM consulted Dr. Walter Bura, in charge of prosthesis of the Veterans Administration. It is printed with the reservations he makes. Dr. Bura says that, technically

leg" which U. S. doctors believe will answer the prayers of thousands of legless war veterans is being tested with gratifying results in Germany today.

Analysis of Performance in Sine-Pursuit Test.
(Drs. Bensinger, Meier-Leibnitz, Kitzinger)

Problem: Although tests of the pursuit variety have been employed in the United States for some time and have proved their value in selection procedures, very little attempt has been made to analyse the performances involved and, from such an analysis, to discover what characteristics of a test contribute most to its predictive value.

Status: Improvements have been made in the apparatus which ensure greater control of the test conditions. A number of preliminary runs have been made. In these, it was found possible to isolate an oscillating movement of very low amplitude and high frequency (8-11 cycles per second). This oscillation appears to be identical to the antagonistic rhythm observed by Lehmann and believed by him to be a reliable and relatively immutable index of motor aptitude. A study is also in progress on the development of target leading and the concomitant changes in response. Further work depends upon the construction of mechanical scoring devices for the evaluation of the various logically derived aspects of performance. One such device is completed and others are under contruction.

✓ **Development of a Standard Control.** (Dr. Henschke and Ing. Mauch)

Problem: Although the tasks of steering an automobile, an aircraft, a directed missile, etc., have many common elements, a different type of control is employed for each. A standard control should allow transfer of efficiency from one steering task to another and, at the same time, provide an accuracy and speed of learning not possible with the present, arbitrarily designed controls.

Status: A bi-dimensional pursuit task has been set up as a criterion to be employed in the evaluation of various types of controls. Under local anesthesia some preliminary experiments on the role of the different tactual senses in the accuracy of control manipulation have been performed.

✓ **Development of an Improved Panel.** (Dr. Henschke and Ing. Mauch)

Problem: The modern instrument panel has become unwieldy, disorganized and so large as to exceed the effective visual field. Demands upon the flexibility of attention are excessive.

Status: A simplified panel with uniform, closely adjacent instruments in the form of parallel vertical slots has been constructed. Experimental evaluation is planned but this project has been inactive during the month of March.

✓ **Development of Improved Prostheses.** (Dr. Henschke and Ing. Mauch)

Taking up about 50% of his time.

Problem: It is believed that real advances in prostheses can result only from the application of new principles. Two new priciples are now being explored: the use of hydraulic power in the prostheses for upper thigh amputees, and a coiled-spring finger in the artificial hand.

Status: An artificial leg has been constructed and an amputee trained sufficiently (3 hours) to demonstrate its superiority to other

Henschke's projects are ① Training — No progress
② Cockpit design — No progress
③ Lifting devices — No progress

133

appliances. This development will be reported in a movie to be filmed in April. No further progress has been made in the development of an artificial hand.

2. **OPERATIONS DIVISION**

a. **Monograph Project.**

Those articles for the monograph on aviation medicine assigned to members of the permanent scientific staff have been completed. The greater part of the contributions from non-staff members have also been received; the few manuscripts not yet submitted are expected within the next month. Each chapter will be edited in German before being submitted for translation.

b. **Laboratory Projects.**

The Application of Linear Grating and Molecular Spectra to Problems of Colorimetry.

Theoretical investigations have been continued, using a mathematical formula which describes the elementary curves of color sensation. This has been applied to observed data. Two sets of curves have been computed, and the agreement elicited between theoretical and empirical data is excellent. At the present stage, there is an indication that none of the hitherto popular theories of color vision is satisfactory in explaining the data. On this basis a revised color theory will be proposed.

The EEG as a Warning Device in Anoxia and Fatigue.

Progress has been made in improving the range and amplification of the instrument, but further work is indicated in insulation of the wiring to the pre-amplifier. It is planned to build a second channel for signalling oscillations of a .003 sec. frequency or less. (The existing channel is for .01 sec. or less).

The Effect of Low Barometric Pressure upon Color Thresholds.

Preliminary experiments were performed at sea level and the color thresholds for red, green, yellow, and blue were measured. Experiments were done at various hours of the day and for various lengths of time. It was determined that there is a diurnal relationship with peak threshold at 3 to 4 p.m., and that threshold values fluctuate depending upon space brightness. At least ten such measurements must be made because of great dispersion of observed values.

Development of Linear Arbitrarily Scaled Instrument Panel for Aircraft.

Measurements were made of the time necessary to scan 12 instruments of a standard P-47 instrument panel and to select any dials on which values outside the permissible range were indicated. Similar observations were made using a mock-up of a linear instrument panel. Test conditions, in each case, were changed after each recording of the panel. For the P-47 panel, with round, clock-face instruments, the times were within the range 2 to 10 seconds; for the linear panel, 1/125 to 1/50 second.

HYDRAULIC LEG

A new development in artificial legs permits simultaneous flexion of ankle and knee and is bringing new hope to amputees.

By Brig. Gen. Malcolm C. Grow

Air Surgeon

Many a man came home from the war without an arm or a leg—an amputee—struggling with a difficult task of readjustment to life.

As doctors we are dedicated to the task of rehabilitating these who gave so much. Our goal is to enable them to walk naturally and work naturally.

Their plight lends urgency to the search for perfect prostheses (artificial legs and arms). To the man hobbling along on crutches sympathy is not enough. What he wants is a leg the equivalent of the lost one! We are aware of the limitations of present prostheses which have been little improved since the models developed after the last war, and we are constantly seeking new ideas.

After V-E Day, while investigating the German research in aviation medicine, I came across two scientists, Ulrich K. Henschke and Hans A. Mauch, who had conceived the idea of using the hydraulic principle in artificial legs. Employed by the AAF at Heidelberg, they were encouraged to put aside their other research to concentrate on this new apparatus.

Henschke and Mauch successfully developed two devices: A small hydraulic system which can be installed in present-day artificial legs to control knee action, and a pair of rods to correlate the flexion of knee and ankle into one smooth stepping motion.

The normal human knee can do wonderful and varied things. The most important and frequent movements are in slow and rapid walking, hill climbing, and going up and down stairs. In normal walking the legs must be flexed and *fixed in flexion* in any one of a continuous series of angles. This is exemplified in ascending and descending stairs and in climbing hills. A second function of the normal leg is a slow and gradual flexion when it is bearing the body's weight. Thirdly, the normal knee is capable of extension, as in kicking a football, and it can be held in extension.

For standing on a leg with safety or walking with a natural stride and for ascending and descending stairs and inclines, the knee joint must be held at various angles while bearing the body's weight. This has so far been impossible with conventional legs. The present artificial leg must be held in a straight position while the amputee steps up to the next step, using his good leg.

Moreover, an amputee must beware even small ground obstacles because, if his foot accidently strikes a stone in walking, the older types of artificial legs may buckle under him. This may seem a trivial thing to a person with two good legs, but the amputee must arrest a fall by hopping on his one good leg and a double amputee has no way to prevent a tumble. Attempts have been made to use mechanical knee brakes but the major limitations are size and weight.

The idea of using a hydraulic system was suggested in 1918 by Windler but was not developed. With a light weight hydraulic system that can be installed in present hollow prostheses the knee joint can be fixed at any angle and, more important, the rate of flexion (as in a deep knee bend) can be controlled, even when the weight of the body is being borne by the artificial leg alone.

The advantages are obvious. The amputee can walk down stairs placing the artificial leg on a lower step while bearing his weight on the artificial leg; he can advance the normal leg to the next step instead of using the present clumsy and awkward one-legged method. Similarly, with the piston arrangement to lock his knee the amputee can climb stairs using alternate legs.

An obvious defect of present day artificial legs is the inability to control the ankle. As the artificial leg is swung back and forth in walking, the ankle remains at a 90° angle to the lower leg. To avoid scraping his toes the amputee raises his hip, creating a gait which is characteristic. It is highly desirable to combine knee flexion with ankle flexion.

Henschke and Mauch connected the knee and ankle by means of rods attached to the inner part of the lower leg, allowing a simultaneous flexion of ankle and knee. This simple device improves walking because it allows the toes to be lifted clear as the knee is bent with each step forward, obviating the necessity for raising the whole hip.

This "hydraulic leg" is on its way from Germany. It will be subjected to further tests and refinements by The Surgeon General, Major General Norman T. Kirk, at the Prosthetic Research Laboratory, Walter Reed General Hospital. I am sure our own American inventiveness will be stimulated by this new device, and, while the final form is as yet undetermined, better prostheses are coming. If they do not serve almost as well as a normal limb, they are not good enough. ☆

Bess Furman. 1962. *Progress in Prosthetics.* Washington, D.C.: U.S. Government Printing Office. pp. 105–109 [http://www.oandplibrary.org/assets/pdf/ProgressInProsthetics.pdf].

As World War II drew to its close, the United States Army conducted a highly secret operation which went by the code name "Paperclip." [...]

One of the "Paperclip" scientists, Hans A. Mauch, head of the development of the V-l rocket used in the bombardment of England, also happened to be an expert in technical medicine, particularly prosthetic devices. His rocketry achievement won for him the highest decoration of the German Government.

Indeed, War Department records show that Mr. Mauch was an expert in many things. As a youth, he studied at the Institute of Technology, Stuttgart and Berlin, becoming a Diploma Engineer in Electrical and Mechanical Engineering. From 1930 to 1935, he was chief engineer for technical development at the Zwietusch Works, Berlin. From 1935 to 1939 he was with the German Air Ministry where he first directed the development of testing installations for propulsion systems, then of airfield equipment, and finally of rocket and jet engines. His initiative in the jet-engine field is considered a major reason for the head start Germany had in this field during World War II.

From 1939 to 1945, he was an independent engineer for developments in half a dozen important fields. These were: (1) Hydraulic, pneumatic, mechanical and electrical equipment used in aircraft and motor vehicles, hydraulic-energy transmitting devices, pneumatic-energy-distribution systems, high-performance mechanical-energy transmissions, electric controls and measuring devices; (2) filters for liquid and gaseous substances; (3) airfield cranes, movable ladders and platforms; (4) high-efficiency heat exchangers having low air resistance; (5) the V-l , the ME 262 jet-propelled fighter, and remote-controlled missiles; (6) technical medicine, especially prostheses.

The Army officer who drew these publishable facts from the still-secret files of Operation Paperclip was moved to remark as he read them off: "This man seems to be able to do almost anything he puts his mind on."

When Mauch came to this country in December 1946, the Air Force claimed him for its experimental work at Wright Field, Dayton, Ohio. He developed protective equipment for extending human endurance at high temperatures. One such article of equipment was the United States Air Force "Air Conditioned Suit" which he invented and which was the subject of an article in Life Magazine. At that time, Hans Mauch firmly refused to permit his name to be used. For Hans Mauch is a philosopher as well as an inventor, and his philosophy, given at that time, was: "Although I admit it gives me great professional satisfaction to make contributions to the society I live in, I don't think it is essential for my work as a scientist to be known to a great many people. Much rather than to be famous at the end of my days, I would like to be able to state that I have had one or two dozen really good friends."

While the work at Wright Field claimed all of Mauch's regular employment time, the Air Force encouraged him to continue his prosthetic research and development work in his spare time. This he did in the basement workshop of his Dayton home. In this country, he had married an Austrian woman "Paperclip" scientist, Tatjana Schmid.

For some years, Mr. Mauch did his prosthetic research in collaboration with another "Paperclip" scientist, Ulrich K. Henschke, now a cancer research specialist at Cornell University. The main results of this work so far are two hydraulic systems for above-knee amputees, the "Henschke-Mauch Hydraulic Swing-Control System" and the "Henschke-Mauch Hydraulic Swing-and-Stance Control System." These hydraulic legs, developed under contract with the Veterans' Administration, were accorded by New York University the full-scale testing reserved for highly important developments.

After eleven years of work as a civilian scientist at Wright Field, Hans Mauch resigned. Given as his reason was the fact that private enterprise required his full-time duty. The Air Force immediately appointed him a consultant to enable continuation of his work on the development of a highly advanced environmental test chamber for the simulation of cockpit conditions in supersonic and space vehicles.

The private enterprise to which he could at last devote his energies was the production of hydraulic legs and other scientific inventions in the field of rehabilitative medicine and human-factors engineering. The laboratory building he now has under construction at 3035 Dryden Road, Dayton, will initially have 5,000 square feet of space on two floors and is so planned that it can be expanded to 26,000 square feet.

In the prosthetics field Mauch is also working on a hydraulic ankle and on a chemical power source for upper-extremity prostheses. He conducted the original investigation in Germany on hydrogen peroxide as a possible energy source for artificial limbs. Other activities of his include the development of a reading machine and of guiding devices for the blind, and work on a personal type of air conditioning, an offshoot of his former Wright Field activities. Both the limb prosthetics researches and the aids to the blind are sponsored by the Veterans' Administration.

A visit with Hans Mauch was included in my trip through the Midwest. As pictured by his fellow scientists all over the country, he turned out to be a rare raconteur who, however, abhors seeing his own words in print between quotation marks.

Mauch sees a prosthesis as a device by which man regains lost abilities or provides himself with abilities nature denied him. In this sense, an airplane is a flight prosthesis, a telescope is a vision prosthesis, and an electronic computer is a brain prosthesis.

He calls the swing-and-stance control a "hydraulic brain" located in the artificial leg. He says that throughout the twelve years of its development the initial plans remained unchanged—"just making refinements so it will do everything the amputee wants it to do and nothing he doesn't want it to do."

What the amputee wants the leg to do, he notes, amounts to quite a list: He wants the leg to support him—even in its flexed position—when he stumbles. He wants the leg to yield slowly under his weight when he walks downstairs or downhill. He would like the leg to have swing characteristics of the good leg. He would appreciate it if the leg could be locked at any knee angle. He would like it if all the control functions so far listed could be easily adjusted to match his particular gait and his walking habits.

The list of the things the amputee doesn't want the leg to do, Mauch has found out in his researches, is about as long. He doesn't want the leg to make any noises. He doesn't want it to be significantly heavier than a conventional prosthesis or to have an inferior cosmetic appearance. He would prefer it if the leg needed a minimum of maintenance and repair work. Its price should not be too high, and its life expectancy should not be too short.

The list of what an amputee wants has been included in the new hydraulic leg. The list of what he doesn't want has been ruled out. That all this is nearing accomplishment in twelve years of mostly spare-time activity makes the time period appear relatively short, after all.

Mauch says his World War II work on a rocket which hits the target without a man to guide it is akin in its way to the hydraulic leg—both are simulations of the controls of the human brain, a subject which so fascinated him from earliest youth that it has led him to make numerous inventions in the control field.

In an amputation, he points out, the communication system from brain to leg or arm has been cut off. The ideal thing, the path of the future, he says, is to catch the impulses of the nerve ends and channel them into the prosthesis; and to put pressure and position sensors into the prosthesis and channel their signals through the nerve ends back to the brain.

Eugene Murphy. 1989. Hans Adolph Mauch 1906–1984. *Memorial Tributes: Volume 3*, pp. 258–264. National Academy of Engineering [https://www.nae.edu/189294/HANS-ADOLPH-MAUCH-19061984]**.**

[...] Fortunately, the S-N-S, his well-known hydraulic artificial knee designed to control both swing and stance phases of walking for above-knee amputees, was a well-established product here and abroad (more than 12,000 had been sold). Voluntarily, Mauch had progressively lengthened the warranty period to two years on this ingenious, complex, yet dependable mechanism. [...]

Mauch's third major consulting activity was original research and development in the fields of aviation medicine and prosthetic devices. In this bioengineering sector, Hans Mauch cooperated closely with Ulrich K. Henschke, a radiologist with a Ph.D. in physics. Head of the Aeromedical Institute in Munich, Dr. Henschke worked on a variety of physiological problems.

After World War II, the U.S. Air Force assembled many top German scientists and engineers at Heidelberg. There, Henschke and Mauch collaborated on an important chapter, "How Man Controls," of a two-volume work, *German Aviation Medicine—World War II.* This chapter was a pioneering effort in what later became known as the fields of cybernetics and human factors engineering. Henschke and Mauch also assembled an extensive bibliography of German work on artificial limbs, designed a metal artificial leg that was intended for mass production of components and easy assembly to an individually fitted socket, and constructed a series of models illustrating various concepts for stabilizing the knee joint of an above-knee prosthesis.

In March 1946 the U.S. Army surgeon general sent a team to Europe to survey artificial limbs. In addition to important information on various devices and procedures including the suction socket leg and cineplastic surgery to control arms, the team brought back the Henschke-Mauch bibliography and the concepts they developed involving knee control. Subsequently, Henschke and Mauch went to Dayton, Ohio, late in 1946, to work as civilian employees at the Aeromedical Laboratory of the Wright Air Force Development Center. Yet, they were able to devote only a small portion of their efforts to prosthetics. Later, Mauch and several others worked evenings and weekends in the basement of his small home with support by the Veterans Administration through its National Academy of Sciences' contract.

Hans Mauch became a naturalized U.S. citizen in June 1955. He left the Aeromedical Laboratory in 1957 to set up his own organization, which was incorporated in 1959 as Mauch Laboratories, Inc. The company engaged in research, development, and manufacturing in the biomedical engineering field. [...]

Except for a classified project to develop a novel space suit for the Air Force and NASA, which the company performed from 1959 to 1964, all of Mauch's work until the mid-1970s was devoted to rehabilitation projects sponsored by the Veterans Administration in coordination, through various National Research Council committees, with projects of other agencies. In recent years, after termination of his VA contracts, further improvements in the company's devices were made by Mauch as proprietary developments.

After exhaustive development and evaluation efforts that culminated in a nationwide clinical trial, the original Henschke-Mauch Model A semivoluntary stance-and-swing hydraulic leg for above-knee amputees was shortened, refined, and renamed the S-N-S. A simpler Model B to control only the swing phase was produced briefly in 1963; it has been refined and is currently sold as Model S. Several other companies produced swing-phase units under the Mauch patent, which was assigned to the VA and licensed to others without royalties after training at Mauch Laboratories.

The Mauch swing control provides programmed resistance that automatically varies with knee angle and walking speed, plus the possibility of independent adjustment of resistances to flexion and extension. The stance phase control always allows extension, but automatically imposes a high (but adjustable) resistance to knee flexion except after a brief application of a hyperextension moment, normally after the heel leaves the ground.

The rigid locking of the device is normally undesirable (the residual limb could be injured after stumbling), but it can be obtained voluntarily if desired— for example, for prolonged standing or for driving an automobile with flexed knee. Conversely, very low resistance to flexion can also be ensured for bicycling. These knee control features are superior to other brakes and locks that have been disclosed in literature and patent applications here and abroad for well over a century.

The S-N-S is the sole survivor of many years of effort by numerous capable engineers and interdisciplinary teams supported by substantial government projects. The genius, persistence, and vision of Hans Mauch are demonstrated by his eventual success with the S-N-S, the recent acceptance of the hydraulic ankle, and his yearning to attain a truly voluntary yet subconscious control of swing-and-stance phase movement.

Although this memoir focuses on Mauch's contributions to hydraulic lower limb prostheses, he made thoughtful, ingenious contributions in many fields, including aviation and aviation medicine, space suits, and the human factors aspects of displays and controls. Mauch was the inventor or coinventor of more than eighty patented inventions in nine countries and the author or coauthor of numerous papers and reports. Under VA contract, he developed several types of personal reading machines for the blind, another area he and Dr. Henschke had explored in Heidelberg. His audible-output Stereotoner direct-translation reading aid, which was smaller, lighter, and lower in price than the widely known tactile-output Optacon, reached limited commercial production.

Otha Linton. 2006. Ulrich Henschke. ***Journal of the American College of Radiology*** **3:8:639 [https://doi.org/10.1016/j.jacr.2006.03.016].**

For most of his career in cancer treatment, Ulrich Henschke was noted for mechanical efforts to put exact amounts of ionizing radiation into the tumors of his patients. Notable to those who saw his demonstrations of brachytherapy in the 1960s were afterloading devices to insert radon or artificial isotopes into cervical or uterine cancers. The concept was to position applicators without the radiation sources. Then, using air pressure or hydraulics, the sources would be forced into place and then withdrawn after the intended doses were delivered. The combination of metal fittings, pumps, and rubber tubes leading from radiation safes to the applicators in patients added an unusual touch to a very serious solution to a difficult problem.

Later on, Dr Henschke developed the Janus machine, using low-energy ^{60}Co sources for treatment facilities in rural areas and underdeveloped countries. The approach involved placing the cobalt in a holder in the wall between 2 treatment rooms. The lead shielding could be revolved to treat a patient in either room or to protect against exposures while people were working in both rooms. The machines were installed in Nigeria, Liberia, Jamaica, Haiti, Tanganyika, India, and several states in the United States. [...]

He donated Janus therapy machines for use in African countries, where the resources for modern, high-technology treatment centers were not available. He managed to establish 10 centers in 9 countries.

It was on a trip to Africa in June 1980 that Dr Henschke was killed in a small-plane crash. He was 66.

A.3 Biological Warfare

[According to official histories, the Third Reich did not conduct any significant work on offensive biological weapons research. Officially, what little work was conducted was merely defensive research, aimed at finding methods of protecting against biological weapons in case they were developed and employed by other countries.[4]

The conclusion that wartime Germany did not pursue offensive biological weapons research is based on two sources of information:

- German documents that were discovered and made public by the U.S. Alsos Mission, which was tasked with finding out everything about any German weapons of mass destruction (biological, chemical, or nuclear) during and immediately after the war. Considering that Alsos (a) completely failed to discover Germany's massive chemical nerve agent program during the war, and (b) failed to investigate most of Germany's nuclear program (Appendix D), historians should not put much faith in Alsos's discoveries or conclusions regarding Germany's biological weapons program. At best the information from Alsos can serve as a starting point for far more extensive historical investigations of the biological weapons program.

- Postwar claims by German scientists and officers that they were conducting only defensive, not offensive, biological weapons research. Whatever the true nature of the wartime programs, historians should not put much stock in the scientists' and officers' postwar denials, in view of the fact that those individuals were on trial or in danger of being put on trial for war crimes.

There are a number of reasons to suspect that wartime Germany did actually have a large and advanced offensive biological warfare program:

1. German-speaking scientists had pioneered the whole fields of microbiology and immunology from the nineteenth century through World War II (Section 2.2). Thus they would have been well positioned to lead the world in developing biological weapons if they were so inclined.

2. Germany systematically harnessed scientific innovations to develop a wide variety of advanced weapons during the war—rockets, missiles, jets, infrared night vision, nerve agents, directed energy weapons (Appendix C), etc. It would have been inconsistent not to harness scientific innovations in microbiology for weapons.

3. Germany aided and worked closely with Japan, which is well known to have possessed and employed biological weapons during the war.

4. A number of wartime intelligence reports described the research, production, and even stockpiling of biological weapons. For some examples, see pp. 2518–2557.

---

[4] See for example: Barenblatt 2004; Blome 1941; Michael Carroll 2004; Deichmann 1996; Geißler 1998a, 1998b; Gold 1997; Guillemin 2005; Haagen 1941; Friedrich Hansen 1993; Sheldon Harris 2002; Kater 1989; Keremidis 2013; Klee 2001; Leitenberg and Zilinskas 2012; Posner and Ware 2000; Regis 1999; Reinhardt 2013; Vivien Spitz 2005; Tokyo War Crimes Trial 1950; U.S. Army 1956.

5. Alsos found many groups and individuals that were part of an (allegedly only defensive) biological warfare research program called Blitzarbeiter (Lightning Worker) in some documents and Blitzableiter (Lightning Rod) in other documents. Much of their work could have also been used for offensive purposes, or Alsos might easily have missed groups, locations, or scientists doing offensive work. See pp. 2559–2569. Among the scientists mentioned by Alsos:

   (a) Kurt Blome (German, 1894–1969) seems to have managed offensive biological warfare programs during the Third Reich, provided information and materials to build up the wartime Japanese biological warfare program (e.g., Unit 100 and Unit 731[5]), and worked for the U.S. Army to transfer related technologies after the war.

   (b) Eugen Haagen (German, 1898–1972) was one of the preeminent virologists in the world before the war, apparently tested biological warfare agents and novel vaccines on human subjects during the war, and continued to conduct research after the war.

   (c) Heinrich Kliewe (German, 1892–1969) seems to have played critical roles during the Third Reich in developing greatly improved methods of growing and disseminating biological agents, revolutionary technologies that formed the core of postwar biological warfare agent work in the United States, United Kingdom, Soviet Union, and other countries.

   (d) Walter Schreiber (German, 1893–1970) apparently managed defensive biological warfare programs during the Third Reich (although that involved forced experimentation on humans), then worked for the U.S. Air Force School of Medicine after the war.

   (e) Erich Traub (German, 1906–1985) evidently developed and tested bacterial and viral agents for military use against farm animals during the war, then after the war helped to build up related programs at the U.S. Plum Island Animal Disease Center, Army Biological Laboratories, and Naval Medical Research Institute.

   (f) A number of other German-speaking biological warfare experts (e.g., Anna Bürger) were identified and recruited by Allied countries after the war.

6. Some surviving and declassified documents show equipment for working with biological agents and disseminating airborne biological agents with nebulizers and other aerosol sprayers. They also show wind speed and animal information for field trials of biological warfare agents, and test results for trials with at least seven biological warfare agents: a *Staphylococcus* species, a *Shigella* species, typhus (*Rickettsia prowazekii*), cholera (*Vibrio cholerae*), plague (*Yersinia pestis*), anthrax (*Bacillus anthracis*), and anthrax spores. See Figs. A.200–A.204.

7. The Reichsinstitut für Krebsforschung (Reich Institute for Cancer Research in Poznan, Poland) was a specially built secure biological research facility that operated from 1942 until it was taken over by the Soviet army in 1945. Virtually all documentation about the institute and its work were destroyed by the Third Reich or captured by the Soviets. Officially it was a cancer research institute, but the facility's design suggests that it was a biological warfare research laboratory, arguably the most advanced facility of that type in the world at that time (Fig. A.205).

8. The Reichsinstitut für Grenzbereiche der Medizin in Geraberg (Reich Institute for Frontiers of Medicine in Geraberg, Thuringia) was under construction and at least partially operational from 1944 to the end of the war (Figs. A.206–A.208). It received many of the scientists and supplies that had been evacuated from the Poznan laboratory.

9. Many other locations throughout territory controlled by the Third Reich may also have been used to develop, produce, and/or test biological weapons—university laboratories, industrial sites, government laboratories, military installations, and underground facilities. After the war, much of that territory was occupied by Soviet forces and not open to investigations by other countries.

10. Germany destroyed a large amount of documents and material at the end of the war in order to preserve its secrets. It would be far easier to destroy biological weapons than chemical or nuclear weapons—bleach or heat would kill bacteria or viruses to prevent postwar discovery by Allied forces.

11. There were postwar reports about knowledge and/or agents surviving from the wartime biological weapons program. See p. 2576 for an example.

12. If Allied countries did discover evidence for wartime German biological weapons, they would have had strong incentives not to make that evidence public, both to arm themselves against rival nations and to claim that their own scientific prowess was greater than that of Germany or other countries. In fact, a U.S. intelligence card catalog shows that there were a number of wartime and postwar reports detailing German production of biological warfare agents, but those reports are still classified and unavailable to the public (Figs. A.210–A.209).

Thus there is currently some evidence that Germany may have actually made major advances in biological warfare research and development during the war, and that German-speaking scientists may have subsequently transferred those methods and materials to postwar biological warfare programs in the United States, United Kingdom, Soviet Union, and other countries. Much more research should be conducted in archives and even at some of the suspected physical sites involved in order to determine the true extent and history of biological warfare work in wartime Germany. While bioweapon development may not be viewed as an honorable field of research (harnessing microbiological knowledge to cause diseases instead of to cure them), the revolutionary nature of the actual science is noteworthy, and the long-term impact on Cold War military programs, modern concerns about bioterrorism, and even research on clinical pathogens and therapeutics has been profound.]

Robert Harris and Jeremy Paxman. 2002. *A Higher Form of Killing: The Secret History of Chemical and Biological Warfare.* 2nd ed. NY: Random House. p. 91.

Both Polish and Russian partisans used biological weapons in sabotage operations against the Germans. In December 1942, for example, the Gestapo discovered a germ warfare arsenal in a four-room Warsaw house used by the Polish underground. They reported to Himmler the discovery of "three flasks of typhus bacilli, seventeen sealed rubber tubes presumably containing bacteria, and one fountain pen with instructions for use for spreading bacteria." Twenty pounds of arsenic had also passed through the house. A few days later, Himmler showed Hitler a captured NKVD order instructing Russian partisans to use arsenic to poison German troops. The raid on the Warsaw house apparently failed to prevent the Poles from continuing to use germ weapons. The Combined Chiefs of Staff learned from the Polish liaison officer in Washington, Colonel Mitkiewicz, that in the first four months of 1943, 426 Germans had been poisoned by the Polish underground; that seventy-seven "poisoned parcels" had been sent to Germany; and that "a few hundred" Nazis had been assassinated by means of "typhoid [typhus] fever microbes and typhoid [typhus] fever lice."

W. Seth Carus 2001. *Bioterrorism and Biocrimes: The Illicit Use of Biological Agents Since 1900.* Revised ed. Washington, D.C.: National Defense University. p. 88. [https://wmdcenter.ndu.edu/Portals/97/Documents/Publications/Articles/Bioterrorism-and-Biocrimes.pdf]

Another source, a member of the Polish underground during the Second World War, claims that the State Institute of Hygiene, apparently located in Warsaw, Poland, was used by the Polish resistance, then known as the Union for Armed Resistance (ZWZ). According to this account, the German Gestapo received anonymous letters denouncing people for various purposes. In many cases, the letters were written to settle grudges, but the fake charges were sufficient to get the victims arrested by the Germans. To put a halt to this practice, the staff of the Institute of Hygiene prepared anthrax cultures, and infected fake anonymous letters that were sent to the Gestapo. When Gestapo agents began to suffer from the symptoms of cutaneous anthrax, they started throwing away anonymous letters without opening them.

[Although the two sources above concern the resistance, they do illustrate that the knowledge, resources, and willingness to make biological weapons were all available in wartime Europe.]

Concern for German Bacteriological Warfare [AFHRA 43811 electronic p. 1075]

Concern for German Bacteriological Warfare

Memo from BG Tom White, AC/S Intelligence to [Henry] Arnold, Feb 8, 1944 quoting from a special report on German secret weapons which indicated that Germany was capable of using BW and had at least two suitable agents "X" and "N," and that either could be dispersed from pilotless planes. White said there were no methods of detection known and decontamination methods were not known.

White reported that a special outlet valve filter for standard US gas masks would be available in quantity to equip all US troops in the UK by May 1, 1944. Also that anti-toxin for up to 400,000 US troops against "X" would be available by May 1, 1944.

White also reported that officers specially trained in BW were being sent to various theater commanders within the next month.

From Bern, Switzerland to Shepardson, OSS. IN-8398. 25 April 1944 [NARA RG 226, Entry A1-134, Box 216, Folder 1359 IN TOLEDO].

#3152-3. TOLEDO. In reference to our #2481 and #2750.

Through a trustworthy middleman we have received an additional short item from Briault indicating that the information given earlier is still in effect and that "when dogs are inoculated with serum from Leporides infected with Tularemia, a dry bacillus is produced which is extremely poisonous and contagious, and which causes terrific congestion." We are also advised that in Paris dogs are being requisitioned in large numbers, and that Tularemia is being studied by Japanese scientific groups. The same informant declares that a bombing attack should be launched against St. Gobain at Chauny where containers are produced. However, we are also advised that prior to the bombing photographs should be made of the place so that new works buildings may be identified.

From Bern to Shepardson, OSS. IN-8654. 28 April 1944 [NARA RG 226, Entry A1-134, Box 216, Folder 1359 IN TOLEDO].

#3215. TOLEDO.

We have additional information on Doctor Briault to the effect that he was placed under arrest at the close of 1942, with the 2nd Bureau of Marine at Vichy, and was released in April of the following year. We have heard that the Director of the Pasteur Institute at Tunis knows him, and that perhaps he is known at the Pasteur Institute in Algiers as well.

The following information was supplied by an untried source: 6 months ago, the Germans took over the brewery located in Weimar, at #9 Schuetsengasse, to convert it for bacteriological warfare purposes.

From Shepardson, OSS to Ustravic, London. OUT-7967. 29 April 1944 [NARA RG 226, Entry A1-134, Box 216, Folder 1360 OUT TOLEDO].

#40034. TOLEDO. From 154 to Cecil.

Data compiled from 2 accounts indicates the following: The Nazis have commenced the propagation of rats on a big scale at the Kastrup Airdrome. All the bigger airdromes in Denmark are equipped with similar propagating stations. It appears that the Nazi plan to drop diseased rats on enemy countries. These accounts are SL/67, from a trustworthy Polish source in London and dated the 25th of February and #1411/44 from Polish Intelligence and dated the 8th of January.

Is is possible to obtain an estimate of the rat population now at Kastrup and other airdromes at present engaged in propagation?

Are these rodents gray, white or black in coloring? What shade is the most numerous and what color is the second most prevalent? Do they treat the rats? Has the rodent population in these various localities been allowed to increase; do they slaughter them and burn them; have the rats been let loose in enemy territory?

From Bern to Shepardson, OSS. IN-9714. 12 May 1944 [NARA RG 226, Entry A1-134, Box 216, Folder 1359 IN TOLEDO].

#3418-22. TOLEDO. To Jackpost and Cecil, London, Action: Washington
Information: London   In reference to your #1576 and #1591.

Further information on Dr. B. has been secured by 401 through an envoy who has just come from France. This information will have to be checked, since it originated with Dr. B. himself. The doctor is a personal friend of Labarthe, who is now in London, as well as of Louis Marin, who is in Algiers at present. He was an assistant to Professor Wurmser and also worked under Professor Laugier who are now in Rio and Algiers, respectively. He maintained contact with Bobschow (sic) at Vichy until November 1942.

According to the notes which are not entirely clear, Dr. B seems to have been Laboratory Chief at the Rothschild Foundation; he maintains that he was a "Fellow" of the Rockefeller Foundation as well.

Concerning the bacteria: German war laboratories are experimenting with 5 elements as follows: Melitococci, Typhus exanthematique, Bacillus tularensis, Morve and Peste pulmonaire. The chances of these bacilli being used eventually are as follows: 3 out of 10 for the Melitococci, 6 out of 10 for the Typhus, and 1 out of 10 for the other 3.

Mediocre success accompanied experiments with torpedoes and bacteria shells in Russia, temperature conditions being a disadvantage there. Although a plan for large scale bombardment of embarkation camps on the English coast has been considered it has not been put into effect because "the receptacle to hold the bacteria is being re-examined and ought to be modified. The germs are preserved by drying and freezing. They should undergo an important change the moment they are discharged because experiments with these toxic powders in Russia have been disappointing. They catch on fire at the moment of deflagration (sic)".

The St. Gobain factory has just been enlarged and receptacles are being manufactured in the newly built additions. This factory seems to be the only one to manufacture these receptacles in an unbreakable material.

A good many dogs were collected in Paris by the Germans for the purpose of experimentation in bacteriology. German laboratories are actively engaged in the production of anti-typhus vaccine and French professors who were deported to Germany are working on problems involving typhus and the tissues. These professors are working in the laboratories at the Buchenwald Camp, which is located near Weimar.

According to Dr. B., the Scientific Research Service of the German Army is the source of the above information. Note from 110: I am sorry that I have no way of determining the dependability of Dr. B.

From Exdet, Algiers to Shepardson, OSS. IN-17824. 20 August 1944 [NARA RG 226, Entry A1-134, Box 216, Folder 1359 IN TOLEDO].

#48364. Green and Mitchell to Washington, information Rome and Caserta. Relay of Bari #433.

We have received a report from English sources dated August 12 says that 1,000,000 bottles of disease-producing germs, mainly cholera and plague, have been prepared in Osijek by the Nazis for use against regions held by large forces.

Klaus Reinhardt. 2013. The Entomological Institute of the Waffen-SS: Evidence for Offensive Biological Warfare Research in the Third Reich. *Endeavour* 37:4:220–227.

In January 1942, Heinrich Himmler, head of the Schutzstaffel (SS) and police in Nazi Germany, ordered the creation of an entomological institute to study the physiology and control of insects that inflict harm to humans. Founded in the grounds of the concentration camp at Dachau, it has been the focus of previous research, notably into the question of whether it was involved in biological warfare research. This article examines research protocols by the appointed leader Eduard May, presented here for the first time, which confirm the existence of an offensive biological warfare research programme in Nazi Germany.

Professor Hellmuth Simons German-Jewish refugee professor of biology and who formerly did research in connection with bacteria warfare at I.G. Farben, now at Zurich Polytechnic Institute believes that German secret weapon will consist of bacteriological warfare with Toxin "Bacillus Botulinus". Claims this Toxin easily produced on large scale in plants such as Behring Works at Marburg, I.G. Farben at Hoechst or at Research Laboratory of Heereswaffenamt Hardenbergstrasse Berlin. Informant states he worked at British Museum Library and at Monteno Institute Cambridge where well known Prof. Keilin and also to Wickham-Steed.

Informant's evidence seems to be of general deductive character rather than based on precise new evidence from Germany itself. Kindly advise whether this matter has sufficient interest to you to justify following up preliminary memorandum he has furnished me.

Through 284-A, we received the data on this subject which is given below. The report is not completely intelligible: From a German source, Doctor Briault of the Pasteur Institute receives information about the preparing of a bacteriological combination containing the following ingredients in the given proportions (French expressions are used):

50%	Tyhuse Anthematique
30%	Psittacose
10%	Peste
10%	Morve

For Morve, Peste and Psittacose, vaccines are unknown; only the Pasteur Institute knows of a vaccine for Typhuse Anthematique. St. Gobain-en-Ardennis is making the jars, which are oval shaped, constructed of unbreakable glass with tubes inside of breakable glass to hold the elements. Some sort of escape opening is provided. Additional particulars on this subject are being sought.

We congratulate you on the results you are achieving, as evidenced in the above cables. We have studied these and have prepared the following questions:

1. Have the figures in the March wire been selected as standard percentages or are they still being studied?

2. Has there been a selection of any composition for large-scale production, and if there has been, has it passed the stage of pilot plant production? Indicate location of plants and whether small or large. Submit any information on current production status.

3. How do the Nazis protect their own troops from their own composition? Specific information concerning wearing apparel, gas masks and the like would be appreciated. Does their gas mask offer protection against every element which your 2 wires have listed?

4. What is the effective life of each element, and by what means are the elements preserved?

5. What are the available vaccines against each element listed? Typhus and Peste, as we understand it, have vaccines against them.

6. What ix the reason for the oval shape of the glass jar? Does each element have an individual tube or for what combination of elements does the tube work?

#3215. TOLEDO.

We have additional information on Doctor Briault to the effect that he was placed under arrest at the close of 1942, with the 2nd Bureau of Marine at Vichy, and was released in April of the following year. We have heard that the Director of the Pasteur Institute at Tunis knows him, and that perhaps he is known at the Pasteur Institute in Algiers as well.

The following information was supplied by an untried source: 6 months ago, the Germans took over the brewery located in Weimar, at #9 Schuetzengasse, to convert it for bacteriological warfare purposes.

#40034. TOLEDO. From 154 to Cecil.

Data compiled from 2 accounts indicates the following: The Nazis have commenced the propagation of rats on a big scale at the Kastrup Airdrome. All the bigger airdromes in Denmark a re equipped with similar propagating stations. It appears that the Nazi plan to drop diseased rats on enemy countries. These accounts are SL/67, from a trustworthy Polish source in London and dated the 25th of February and #1411/44, from Polish Intelligence and dated the 8th of January.

Is it possible to obtain an estimate of the rat population now at Kastrup and other airdromes at present engaged in propagation?

Are these rodents gray, white or black in coloring? What shade is the most numerous and what color is the second most prevalent? Do they treat the rats? Has the rodent population in these various localities been allowed to increase; do they slaughter them and burn them; have the rats been let loose in enemy territory?

London advises that the information on the reports given herein was received via Sweden. According to Penguin in London, the source is apt to be dependable. We would like to have this data checked because we are interested in making use of it as basic material:

SL/67, dated February 25, and #1411/11, of January 8, are the reports in question. The former was supplied by dependable Polish source in London and the latter is from Polish Intelligence. They contain the following data: The Nazis have begun breeting rats in hugh quantities at the airdrome of Kastrup. All the larger airdromes in Denmark are equipped with breeding stations of the same kind and the Germans seem to be planning to drop rats on enemy territory after they have been infected.

In addition, we would like to know whether the rats are gray, black or white and approximately how many of each color are kept at the various airdromes. In London, Penguin is busy trying to learn the answers to these questions. Can you supply any further information?

#3418-22. TOLEDO. To Jackpot and Cecil, London, Action: Washington
Information: London In reference to your #1576
and #1591.

Further information on Dr. B. has been secured by 401 through an envoy who has just come from France. This information will have to be checked, since it originated with Dr. B. himself*. The doctor is a personal friend of Labarthe, who is now in London, as well as of Louis Marin, who is in Algiers at present. He was an assistant to Professor Wurmser and also worked under Professor Laugier who are now in Rio and Algiers, respectively. He maintained contact with Bobschow (sic) at Vichy until November 1942.

According to the notes which are not entirely clear, Dr. B. seems to have been Laboratory Chief at the Rothschild Foundation; he maintains that he was a "Fellow" of the Rockefeller Foundation as well.

Concerning the bacteria: German war laboratories are experimenting with 5 elements as follows: Melitococcie,** Typhus Exanthematique, Bacillus Tullarense, Morve and Peste Pulmonaire. The chances of these bacilli being used eventually are as follows: 3 out of 10 for the Melitococcie, 5 out of 10 for the Typhus, and 1 out of 10 for the other 3.

Mediocre success accompanied experiments with torpedoes and bacteria shells in Russia, temperature conditions being a disadvantage there. Although a plan for large scale bombardment of embarkation camps on the English coast has been considered it has not been put into effect because "the reciptacle to hold the bacteria is being re-examined and ought to be modified. The germs are preserved by drying and freezing They should undergo an important change the moment they are discharged because experiments with these toxic powders in Russia have been disappointing. They catch on fire at the moment of deflagration (sic)".

RECEIVED

The St. Gobain factory has just been enlarged and receptacles are being manufactured in the newly built additions. This factory seems to be the only one to manufacture these receptacles in an unbreakable material.

A good many dogs were collected in Paris by the Germans for the purpose of experimentation in bacteriology. German laboratories are actively engaged in the production of anti-typhus vaccine and French professors who were deported to Germany are working on problems involving typhus and the tissues. These professors are working in the laboratories at the Buchenwald Camp, which is located near Weimar.

According to Dr. B., the Scientific Research Service of the German Army is the source of the above information. Note from 110: I am sorry that I have no way of determining the dependability of Dr. B.

SECSTATE WASHINGTON
WATCH

Toledo. Professor Paul Hauduroy, French citizen, head of Bacteriology Dept. Lausanne Univ. Medical School and formerly at Univ. of Paris. Prof. impressed by possibility that Germans may use bacteria in their final effort. States facility of producing in great quantities a dry form of bacteria that retains virulence. Mentions following which may be used individually or in combination (to make diagnosis difficult): Peste pulmonaire, Tularemie, Melioidose, Charbon pulmonaire, Psittacose, Typhus exanthematique, Morve.

Si odieuse et répugnante qu'elle puisse être, la guerre bactériologique est possible et les techniques modernes permettraient, à ceux qui voudraient s'en servir de l'utiliser très largement avec des chances considérables de succès.

Essayant de prendre la mentalité de celui qui voudrait en faire usage, j'envisagerai d'abord " l'idéal à atteindre" puis les moyens qui permettraient d'y parvenir.

Mais dans les procédés qui s'offrent, tous ne sont pas pratiquement utilisables et il y a lieu d'étudier les probabilités.

J'envisagerai enfin les moyens de défense qu'il est possible d'opposer à des attaques effectuées avec l'arme bactériologique.

I. Idéal à atteindre.

Le but est de provoquer chez l'adversaire une maladie grave, mortelle si possible, se répandant facilement et rapidement de l'individu malade à l'individu sain, difficilement diagnosticable, contre laquelle il serait difficile de lutter soit parce qu'il n'existe pas de médicaments, soit parce qu'ils sont en quantité insuffisante.

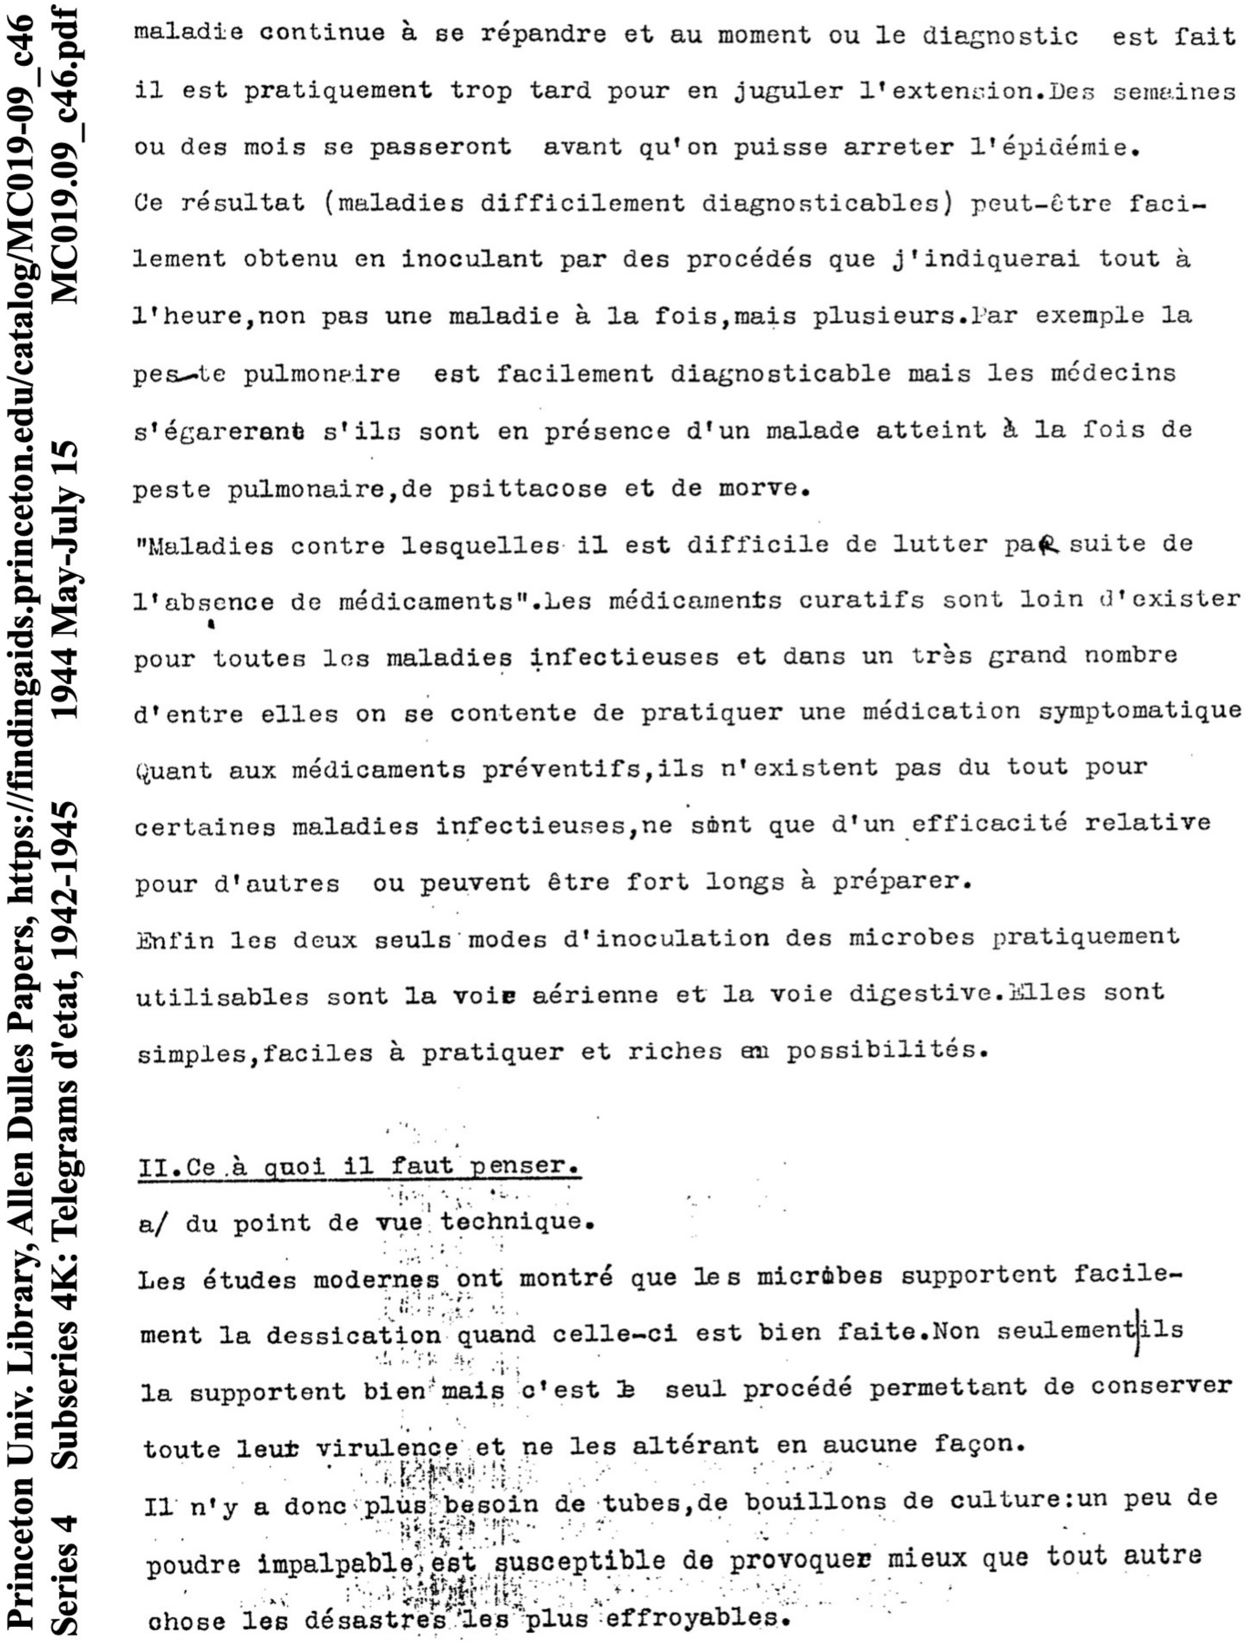
Reprenons quelques termes de cette proposition.

"Maladies épidémiques se répandant facilement de l'individu malade à l'homme sain". Condition essentielle du succès. Les premiers cas ayant été volontairement provoqués, il est nécessaire que l'infection continue à se répandre sans intervention nouvelle.

De telles infections existent: peste pulmonaire, fièvre typhoide, etc..

"Maladies difficilement diagnosticables ". Il y a le plus grand intérêt à ce que les médecins ne puissent pas faire immédiatement le diagnostic, qu'ils s'égarent pendant plusieurs jours. Pendant ce temps, la

Figure A.168: U.S. intelligence reports on apparent large-scale offensive biological warfare preparations in Germany [Princeton University Library, Allen Dulles Papers, Series 4, Subseries 4K: Telegrams d'etat, 1942–1945, 1944 May-July 15, MC019.09_c46.pdf, https://findingaids.princeton.edu/catalog/MC019-09_c46].



Princeton Univ. Library, Allen Dulles Papers, https://findingaids.princeton.edu/catalog/MC019-09_c46
Series 4 Subseries 4K: Telegrams d'etat, 1942-1945 1944 May-July 15 MC019.09_c46.pdf

maladie continue à se répandre et au moment ou le diagnostic est fait il est pratiquement trop tard pour en juguler l'extension. Des semaines ou des mois se passeront avant qu'on puisse arreter l'épidémie.

Ce résultat (maladies difficilement diagnosticables) peut-être facilement obtenu en inoculant par des procédés que j'indiquerai tout à l'heure, non pas une maladie à la fois, mais plusieurs. Par exemple la peste pulmonaire est facilement diagnosticable mais les médecins s'égareront s'ils sont en présence d'un malade atteint à la fois de peste pulmonaire, de psittacose et de morve.

"Maladies contre lesquelles il est difficile de lutter par suite de l'absence de médicaments". Les médicaments curatifs sont loin d'exister pour toutes les maladies infectieuses et dans un très grand nombre d'entre elles on se contente de pratiquer une médication symptomatique Quant aux médicaments préventifs, ils n'existent pas du tout pour certaines maladies infectieuses, ne sont que d'un efficacité relative pour d'autres ou peuvent être fort longs à préparer.

Enfin les deux seuls modes d'inoculation des microbes pratiquement utilisables sont la voie aérienne et la voie digestive. Elles sont simples, faciles à pratiquer et riches en possibilités.

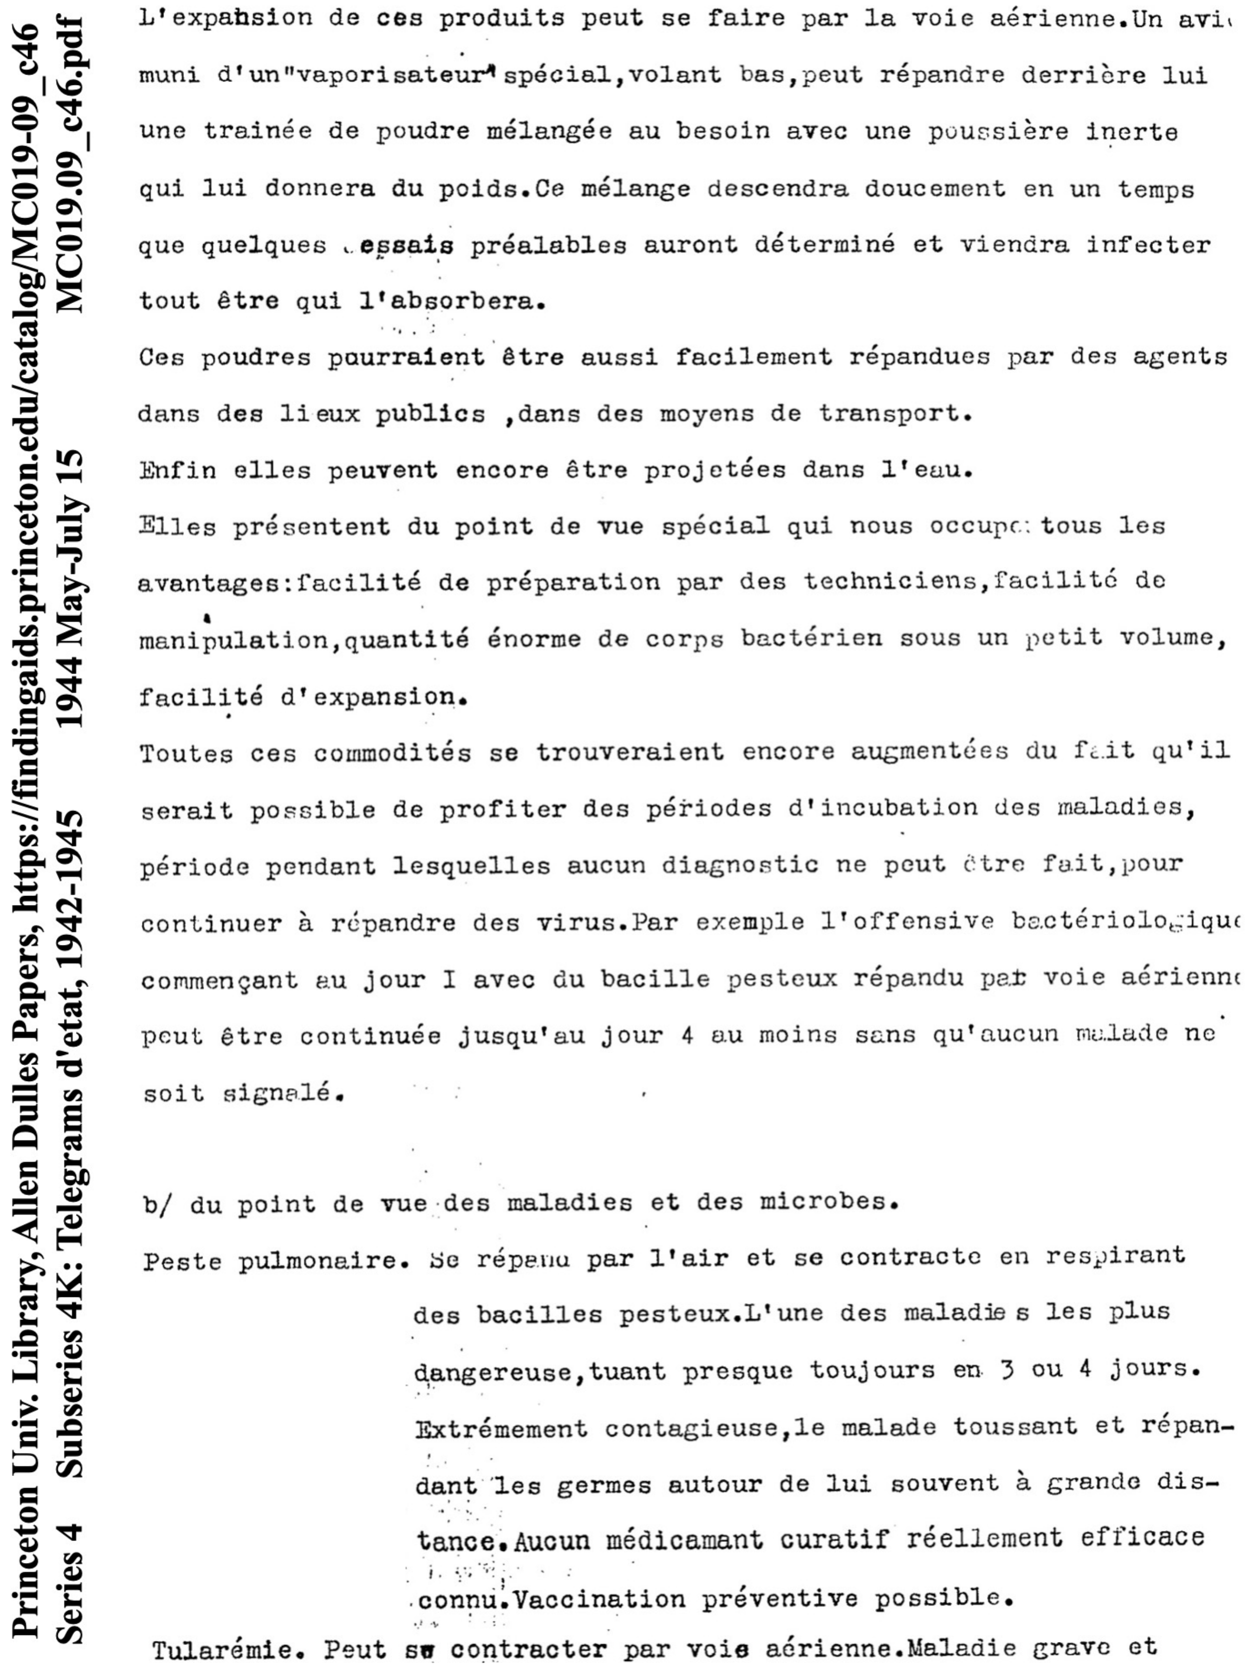
II. Ce à quoi il faut penser.

a/ du point de vue technique.

Les études modernes ont montré que les microbes supportent facilement la dessication quand celle-ci est bien faite. Non seulement ils la supportent bien mais c'est le seul procédé permettant de conserver toute leur virulence et ne les altérant en aucune façon.

Il n'y a donc plus besoin de tubes, de bouillons de culture: un peu de poudre impalpable, est susceptible de provoquer mieux que tout autre chose les désastres les plus effroyables.

Figure A.169: U.S. intelligence reports on apparent large-scale offensive biological warfare preparations in Germany [Princeton University Library, Allen Dulles Papers, Series 4, Subseries 4K: Telegrams d'etat, 1942–1945, 1944 May-July 15, MC019.09_c46.pdf, https://findingaids.princeton.edu/catalog/MC019-09_c46].



Princeton Univ. Library, Allen Dulles Papers, https://findingaids.princeton.edu/catalog/MC019-09_c46
Series 4 Subseries 4K: Telegrams d'etat, 1942-1945 1944 May-July 15 MC019.09_c46.pdf

L'expahsion de ces produits peut se faire par la voie aérienne.Un avi muni d'un"vaporisateur"spécial,volant bas,peut répandre derrière lui une trainée de poudre mélangée au besoin avec une poussière inerte qui lui donnera du poids.Ce mélange descendra doucement en un temps que quelques essais préalables auront déterminé et viendra infecter tout être qui l'absorbera.

Ces poudres pourraient être aussi facilement répandues par des agents dans des lieux publics ,dans des moyens de transport.

Enfin elles peuvent encore être projetées dans l'eau.

Elles présentent du point de vue spécial qui nous occupe tous les avantages:facilité de préparation par des techniciens,facilité de manipulation,quantité énorme de corps bactérien sous un petit volume, facilité d'expansion.

Toutes ces commodités se trouveraient encore augmentées du fait qu'il serait possible de profiter des périodes d'incubation des maladies, période pendant lesquelles aucun diagnostic ne peut être fait,pour continuer à répandre des virus.Par exemple l'offensive bactériologiqu commençant au jour I avec du bacille pesteux répandu par voie aérienn peut être continuée jusqu'au jour 4 au moins sans qu'aucun malade ne soit signalé.

b/ du point de vue des maladies et des microbes.

Peste pulmonaire. Se répand par l'air et se contracte en respirant des bacilles pesteux.L'une des maladies les plus dangereuse,tuant presque toujours en 3 ou 4 jours. Extrémement contagieuse,le malade toussant et répandant les germes autour de lui souvent à grande distance.Aucun médicamant curatif réellement efficace connu.Vaccination préventive possible.

Tularémie. Peut se contracter par voie aérienne.Maladie grave et

Figure A.170: U.S. intelligence reports on apparent large-scale offensive biological warfare preparations in Germany [Princeton University Library, Allen Dulles Papers, Series 4, Subseries 4K: Telegrams d'etat, 1942–1945, 1944 May-July 15, MC019.09_c46.pdf, https://findingaids.princeton.edu/catalog/MC019-09_c46].

Series 4 Subseries 4K: Telegrams d'etat, 1942-1945 1944 May-July 15 MC019.09_c46.pdf

longue (6 à I2 mois) se terminant par la guérison en général.Pas de traitement spécifique connu.La transmission de l'homme à l'homme ne se fait pas sauf par des puces,des punaises,etc..Diagnostic difficile.

Melioïdose(due au bacille de Withmore).Se transmet par des matières alimentaires souillées.Mort presque fatale.Contagion interhumaine inexsistante.Pas de thérapeutique connue.Diagnostic extraordinairement difficile.

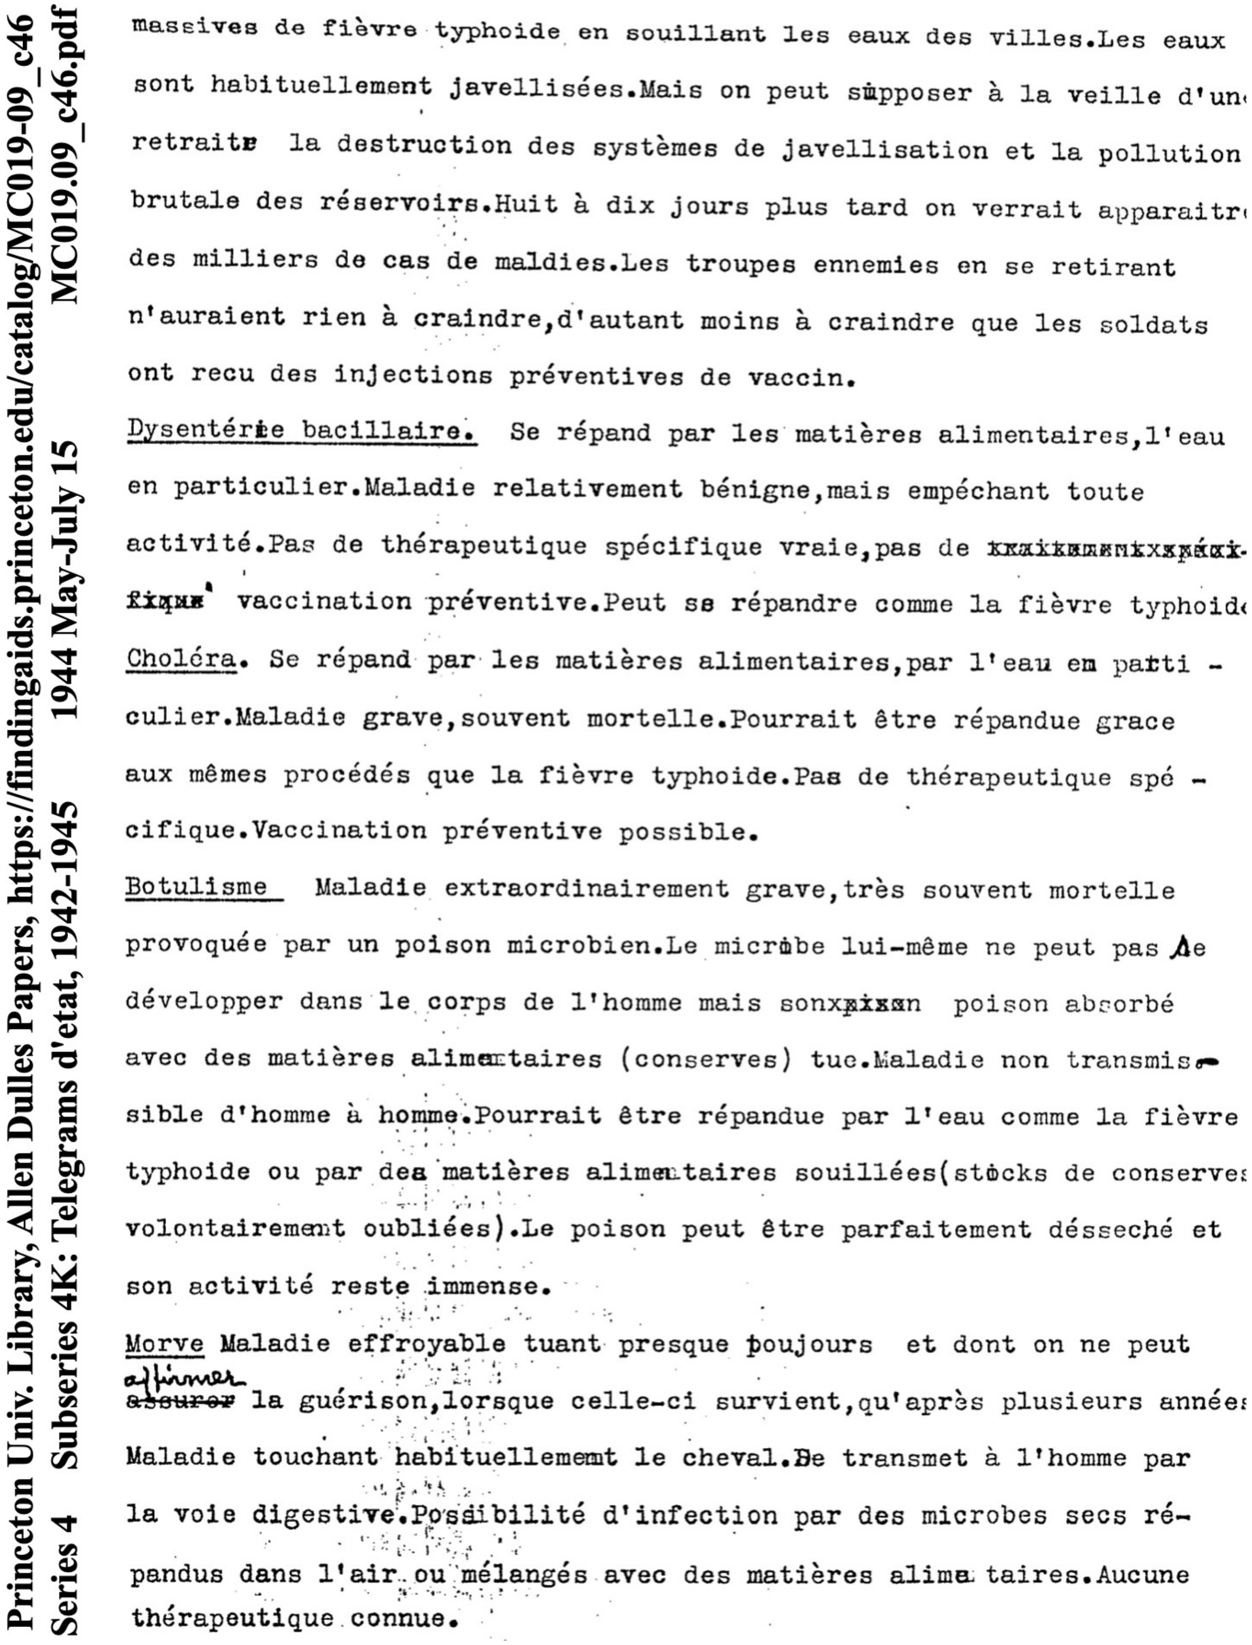
Charbon bactéridien. (Bacillus anthracis) Peut se répandre par l'air (charbon pulmonaire).Maladie grave,souvent mortelle(90% des cas) Différents traitements spécifiques dont l'efficacité n'est pas absolue.Contagieuse d'homme à homme.

Psittacose.(Virus invisible) Peut se répandre par l'air ou par la voie digestive(la plus ususelle) Contagieuse d'homme à homme.Pas de thérapeutique spécifique.Dure 20 jours en moyenne.Mort dans I0 à 20 % des cas.

Typhus exanthématique (Rickettsiae) Peut se répandre ~~dans~~ par l'air bien que ce ne soit pas le mode habituel de contagion.Maladie grave souvent mortelle,d'autant plus grave qu'elle frappe des individus en état de déficience physiologique.La contamination d'homme à homme ne peut se faire que par l'intermédiaire du pou. Thérapeutique spécifique inconnue.Vaccination préventive efficace.

Fièvre typhoide et paratyphoide. Maladies se transmettant par les matières alimetaires et plus particulièrement par l'eau.Maladie grave.Pas de traitement spécifique.Vaccination préventive faite presque partout chez les hommes.Les femmes et les enfants ne sont pas vaccinés en général.Il serait très facile de provoquer desépidémies

Figure A.171: U.S. intelligence reports on apparent large-scale offensive biological warfare preparations in Germany [Princeton University Library, Allen Dulles Papers, Series 4, Subseries 4K: Telegrams d'etat, 1942–1945, 1944 May-July 15, MC019.09_c46.pdf, https://findingaids.princeton.edu/catalog/MC019-09_c46].



Princeton Univ. Library, Allen Dulles Papers, https://findingaids.princeton.edu/catalog/MC019-09_c46
Series 4 Subseries 4K: Telegrams d'etat, 1942-1945 1944 May-July 15 MC019.09_c46.pdf

massives de fièvre typhoide en souillant les eaux des villes.Les eaux sont habituellement javellisées.Mais on peut supposer à la veille d'un retraite la destruction des systèmes de javellisation et la pollution brutale des réservoirs.Huit à dix jours plus tard on verrait apparaitr des milliers de cas de maldies.Les troupes ennemies en se retirant n'auraient rien à craindre,d'autant moins à craindre que les soldats ont recu des injections préventives de vaccin.

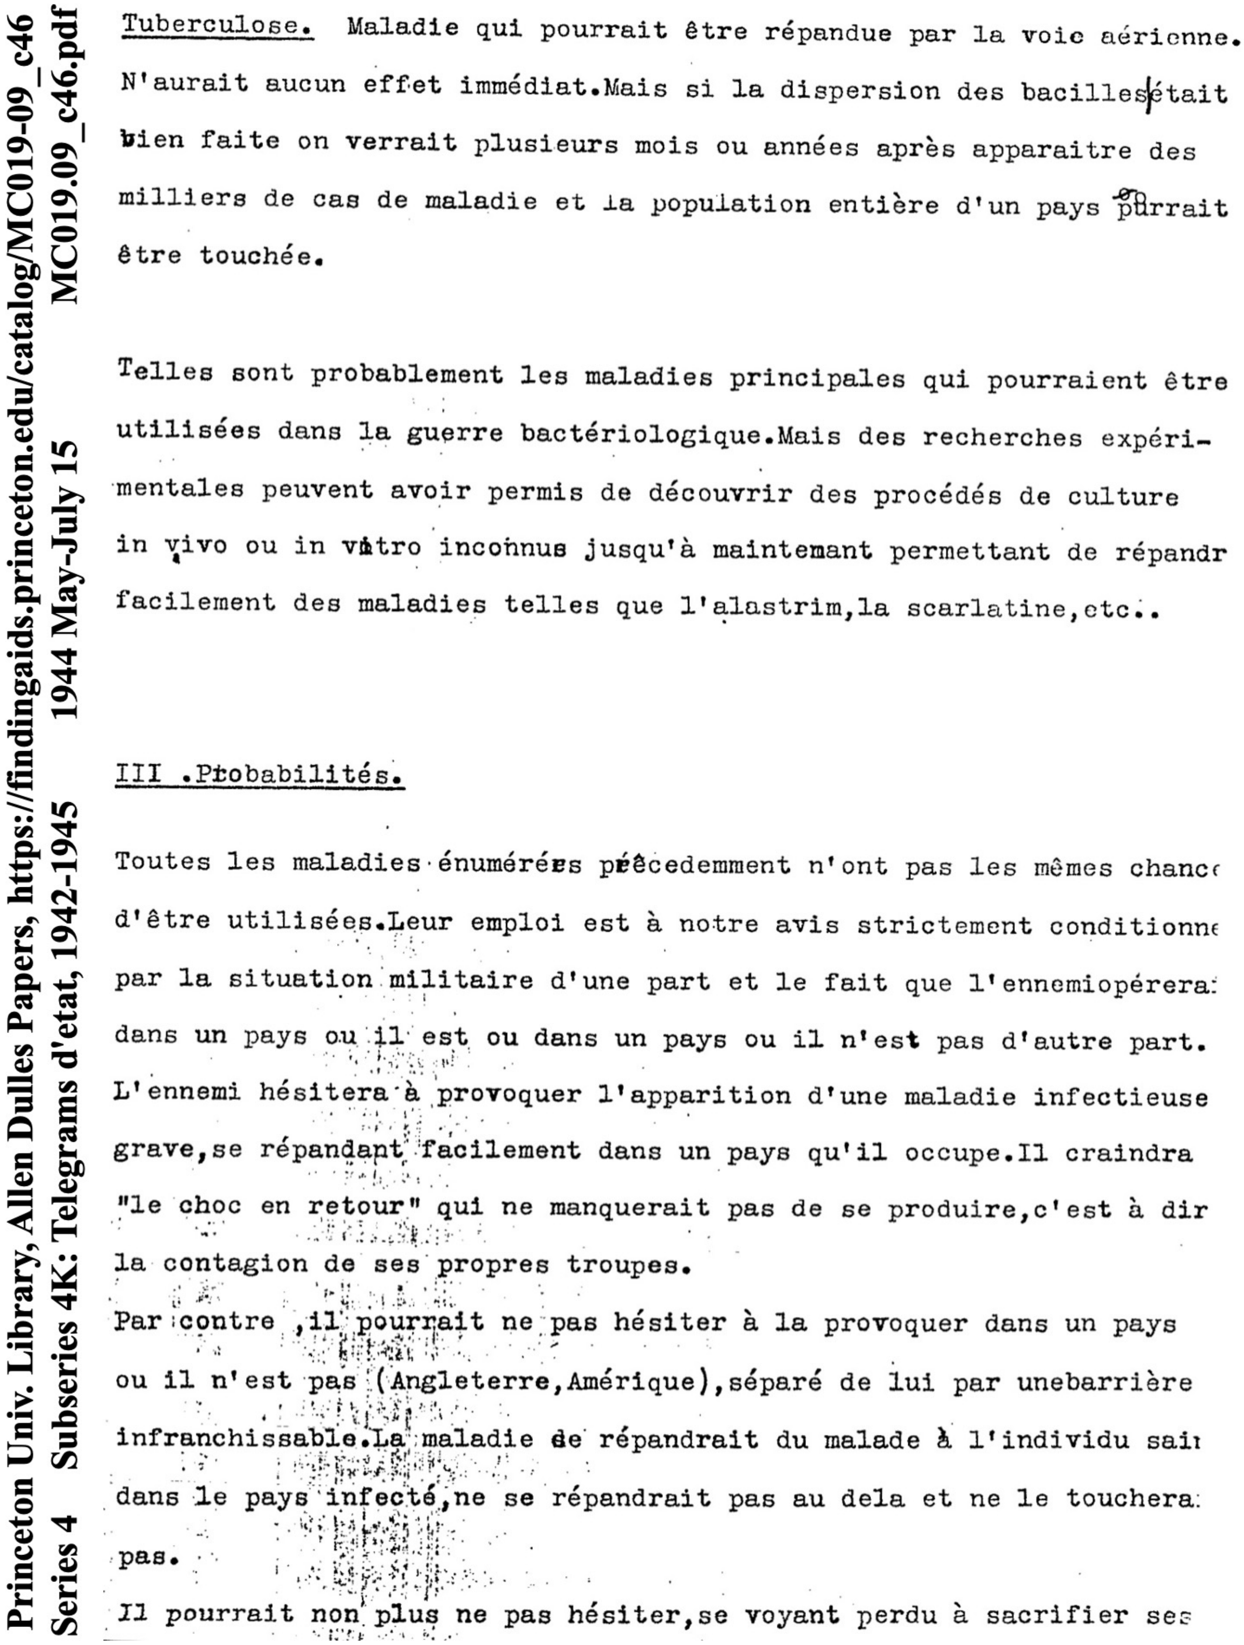
Dysentérie bacillaire. Se répand par les matières alimentaires,l'eau en particulier.Maladie relativement bénigne,mais empéchant toute activité.Pas de thérapeutique spécifique vraie,pas de ~~traitement spécifique~~ vaccination préventive.Peut se répandre comme la fièvre typhoid

Choléra. Se répand par les matières alimentaires,par l'eau en particulier.Maladie grave,souvent mortelle.Pourrait être répandue grace aux mêmes procédés que la fièvre typhoide.Pas de thérapeutique spécifique.Vaccination préventive possible.

Botulisme Maladie extraordinairement grave,très souvent mortelle provoquée par un poison microbien.Le microbe lui-même ne peut pas se développer dans le corps de l'homme mais son ~~poison~~ poison absorbé avec des matières alimentaires (conserves) tue.Maladie non transmissible d'homme à homme.Pourrait être répandue par l'eau comme la fièvre typhoide ou par des matières alimentaires souillées(stocks de conserve volontairement oubliées).Le poison peut être parfaitement désseché et son activité reste immense.

Morve Maladie effroyable tuant presque toujours et dont on ne peut ~~assurer~~ affirmer la guérison,lorsque celle-ci survient,qu'après plusieurs année Maladie touchant habituellement le cheval.Se transmet à l'homme par la voie digestive.Possibilité d'infection par des microbes secs répandus dans l'air ou mélangés avec des matières alimentaires.Aucune thérapeutique connue.

Figure A.172: U.S. intelligence reports on apparent large-scale offensive biological warfare preparations in Germany [Princeton University Library, Allen Dulles Papers, Series 4, Subseries 4K: Telegrams d'etat, 1942–1945, 1944 May-July 15, MC019.09_c46.pdf, https://findingaids.princeton.edu/catalog/MC019-09_c46].



Tuberculose. Maladie qui pourrait être répandue par la voie aérienne. N'aurait aucun effet immédiat.Mais si la dispersion des bacilles était bien faite on verrait plusieurs mois ou années après apparaitre des milliers de cas de maladie et la population entière d'un pays pourrait être touchée.

Telles sont probablement les maladies principales qui pourraient être utilisées dans la guerre bactériologique.Mais des recherches expérimentales peuvent avoir permis de découvrir des procédés de culture in vivo ou in vitro inconnus jusqu'à maintemant permettant de répandr facilement des maladies telles que l'alastrim,la scarlatine,etc..

III .Probabilités.

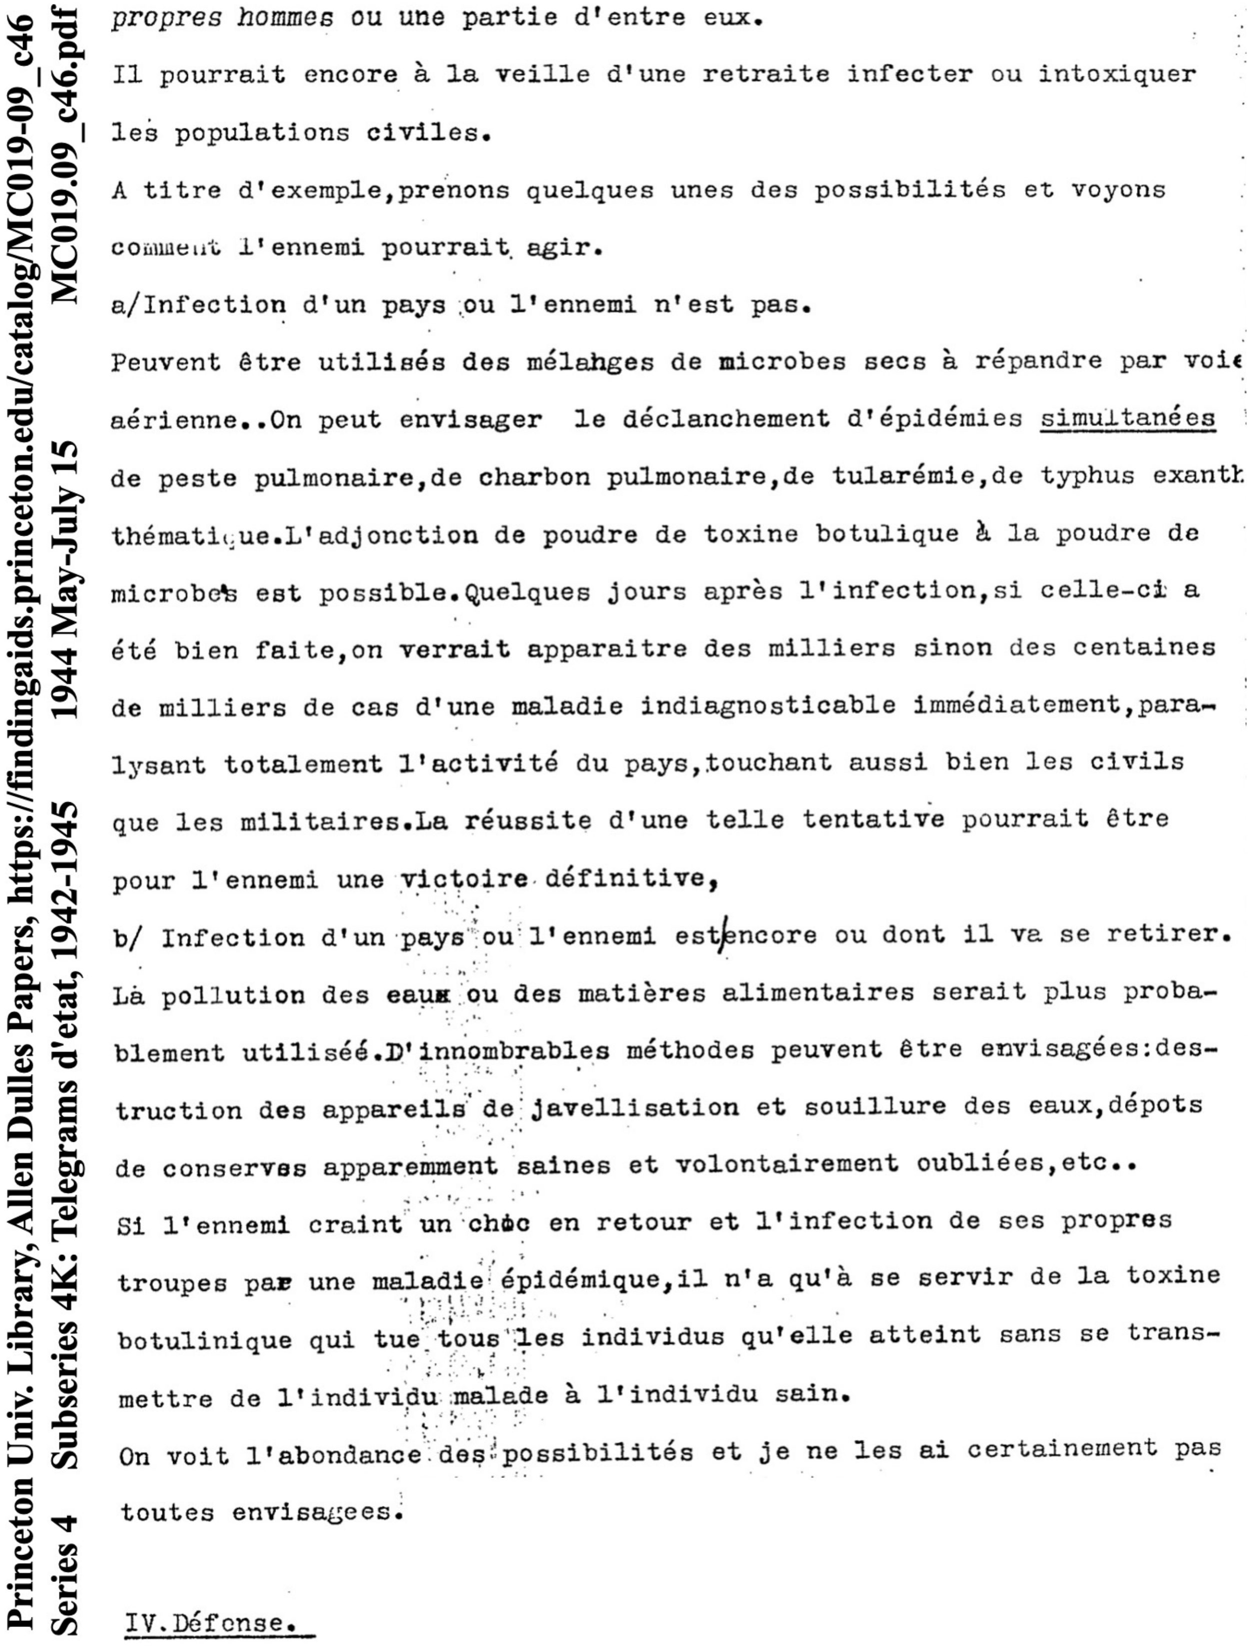
Toutes les maladies énumérées précedemment n'ont pas les mêmes chanc d'être utilisées.Leur emploi est à notre avis strictement conditionn par la situation militaire d'une part et le fait que l'ennemiopérera dans un pays ou il est ou dans un pays ou il n'est pas d'autre part. L'ennemi hésitera à provoquer l'apparition d'une maladie infectieuse grave,se répandant facilement dans un pays qu'il occupe.Il craindra "le choc en retour" qui ne manquerait pas de se produire,c'est à dir la contagion de ses propres troupes.

Par contre ,il pourrait ne pas hésiter à la provoquer dans un pays ou il n'est pas (Angleterre,Amérique),séparé de lui par unebarrière infranchissable.La maladie se répandrait du malade à l'individu sai dans le pays infecté,ne se répandrait pas au dela et ne le touchera pas.

Il pourrait non plus ne pas hésiter,se voyant perdu à sacrifier ses

Princeton Univ. Library, Allen Dulles Papers, https://findingaids.princeton.edu/catalog/MC019-09_c46
Series 4 Subseries 4K: Telegrams d'etat, 1942-1945 1944 May-July 15 MC019.09_c46.pdf

Figure A.173: U.S. intelligence reports on apparent large-scale offensive biological warfare preparations in Germany [Princeton University Library, Allen Dulles Papers, Series 4, Subseries 4K: Telegrams d'etat, 1942–1945, 1944 May-July 15, MC019.09_c46.pdf, https://findingaids.princeton.edu/catalog/MC019-09_c46].



propres hommes ou une partie d'entre eux.

Il pourrait encore à la veille d'une retraite infecter ou intoxiquer les populations civiles.

A titre d'exemple,prenons quelques unes des possibilités et voyons comment l'ennemi pourrait agir.

a/Infection d'un pays ou l'ennemi n'est pas.

Peuvent être utilisés des mélahges de microbes secs à répandre par voie aérienne..On peut envisager le déclanchement d'épidémies simultanées de peste pulmonaire,de charbon pulmonaire,de tularémie,de typhus exanthématique.L'adjonction de poudre de toxine botulique à la poudre de microbes est possible.Quelques jours après l'infection,si celle-ci a été bien faite,on verrait apparaitre des milliers sinon des centaines de milliers de cas d'une maladie indiagnosticable immédiatement,paralysant totalement l'activité du pays,touchant aussi bien les civils que les militaires.La réussite d'une telle tentative pourrait être pour l'ennemi une victoire définitive,

b/ Infection d'un pays ou l'ennemi est/encore ou dont il va se retirer.

La pollution des eaux ou des matières alimentaires serait plus probablement utiliséé.D'innombrables méthodes peuvent être envisagées:destruction des appareils de javellisation et souillure des eaux,dépots de conserves apparemment saines et volontairement oubliées,etc..

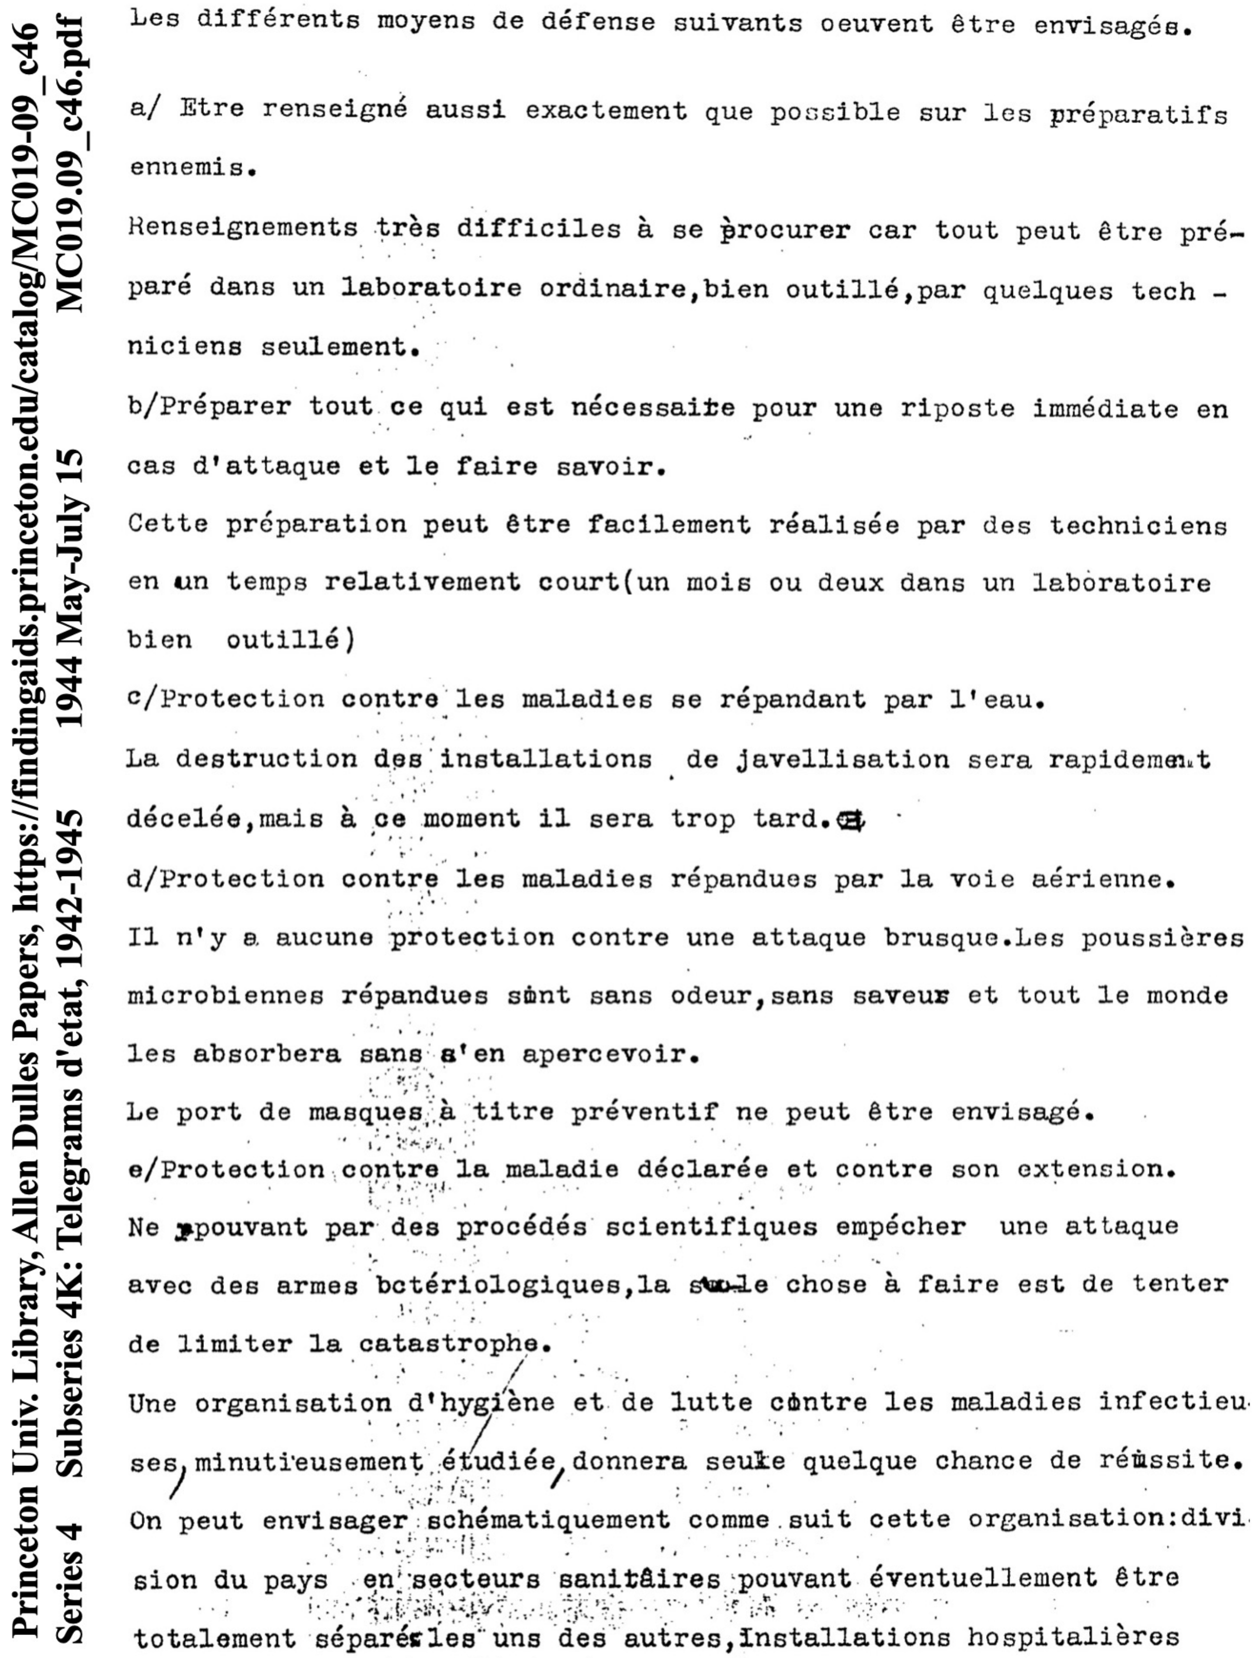
Si l'ennemi craint un choc en retour et l'infection de ses propres troupes par une maladie épidémique,il n'a qu'à se servir de la toxine botulinique qui tue tous les individus qu'elle atteint sans se transmettre de l'individu malade à l'individu sain.

On voit l'abondance des possibilités et je ne les ai certainement pas toutes envisagees.

IV.Défense.

Princeton Univ. Library, Allen Dulles Papers, https://findingaids.princeton.edu/catalog/MC019-09_c46
Series 4 Subseries 4K: Telegrams d'etat, 1942-1945 1944 May-July 15 MC019.09_c46.pdf

Figure A.174: U.S. intelligence reports on apparent large-scale offensive biological warfare preparations in Germany [Princeton University Library, Allen Dulles Papers, Series 4, Subseries 4K: Telegrams d'etat, 1942–1945, 1944 May-July 15, MC019.09_c46.pdf, https://findingaids.princeton.edu/catalog/MC019-09_c46].



Princeton Univ. Library, Allen Dulles Papers, https://findingaids.princeton.edu/catalog/MC019-09_c46
Series 4 Subseries 4K: Telegrams d'etat, 1942-1945 1944 May-July 15 MC019.09_c46.pdf

Les différents moyens de défense suivants oeuvent être envisagés.

a/ Etre renseigné aussi exactement que possible sur les préparatifs ennemis.

Renseignements très difficiles à se procurer car tout peut être préparé dans un laboratoire ordinaire, bien outillé, par quelques techniciens seulement.

b/Préparer tout ce qui est nécessaite pour une riposte immédiate en cas d'attaque et le faire savoir.

Cette préparation peut être facilement réalisée par des techniciens en un temps relativement court(un mois ou deux dans un laboratoire bien outillé)

c/Protection contre les maladies se répandant par l'eau.

La destruction des installations de javellisation sera rapidement décelée, mais à ce moment il sera trop tard.

d/Protection contre les maladies répandues par la voie aérienne.

Il n'y a aucune protection contre une attaque brusque. Les poussières microbiennes répandues sont sans odeur, sans saveur et tout le monde les absorbera sans s'en apercevoir.

Le port de masques à titre préventif ne peut être envisagé.

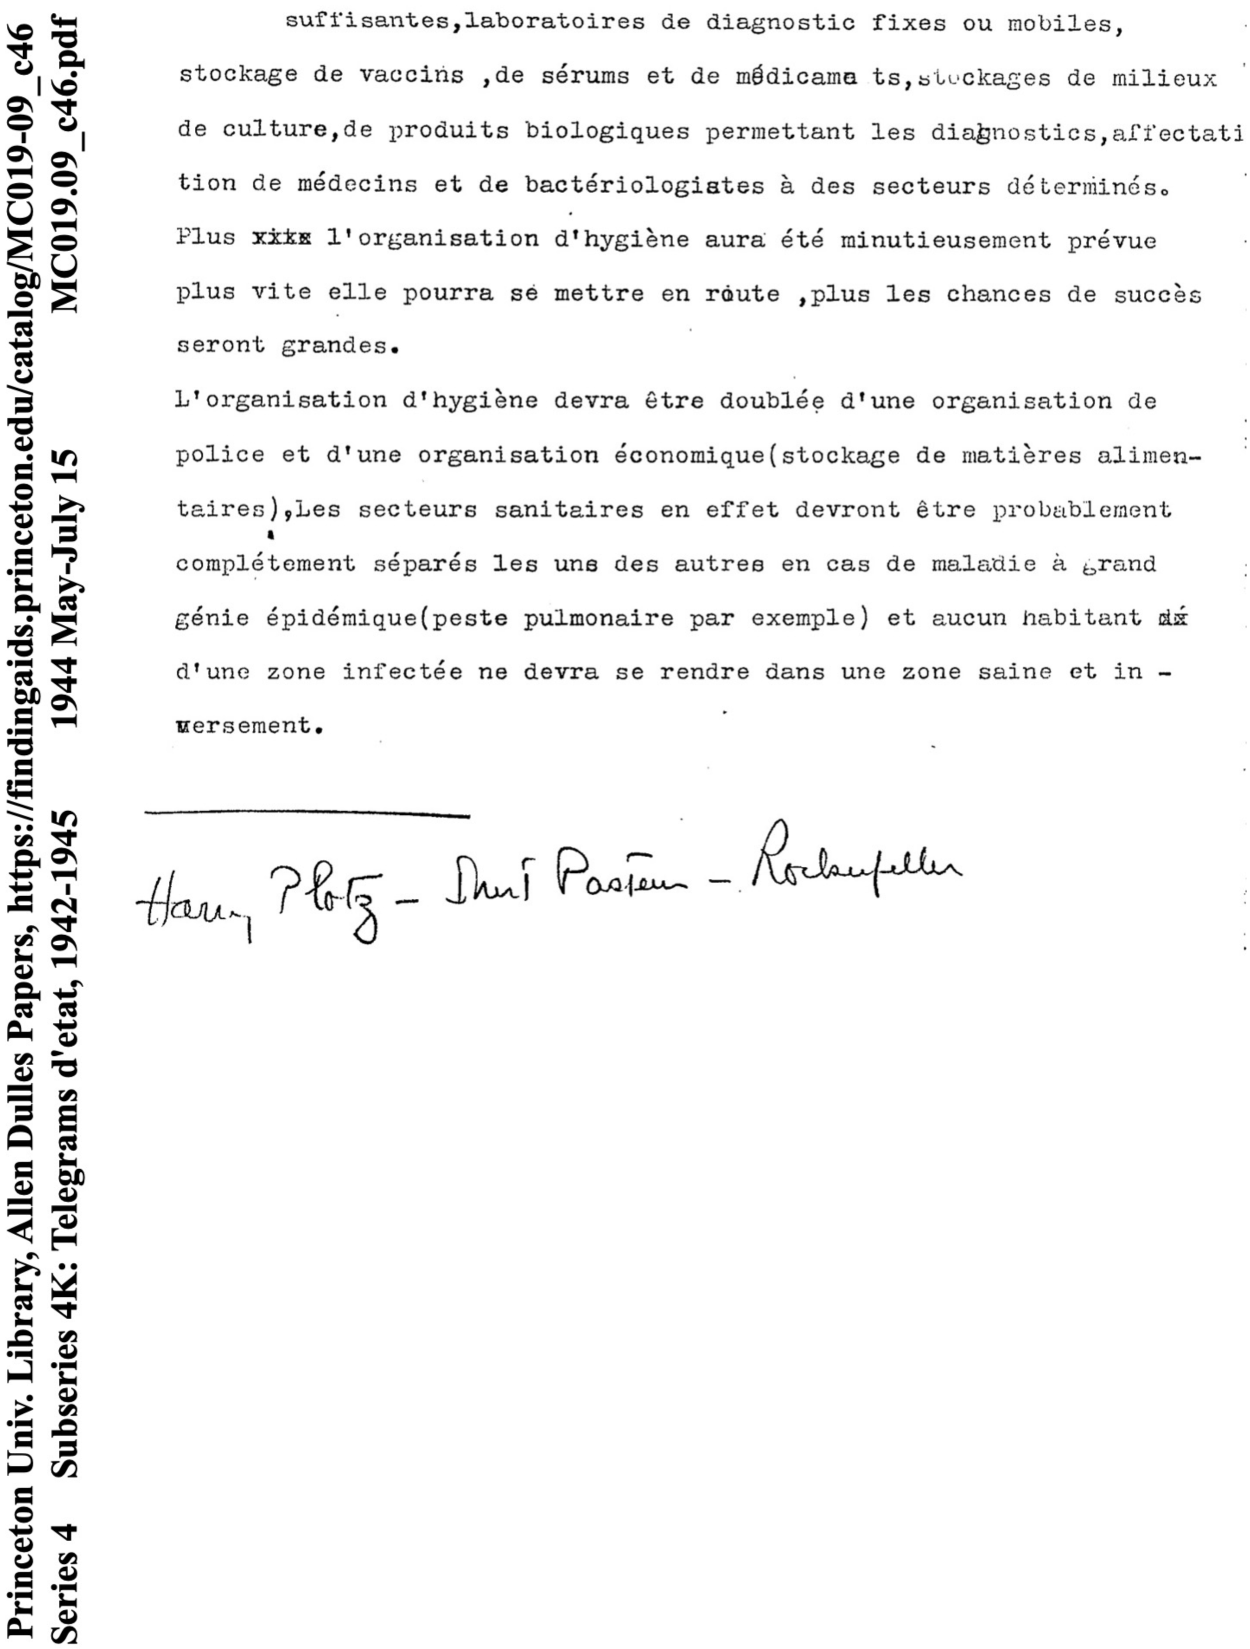
e/Protection contre la maladie déclarée et contre son extension.

Ne pouvant par des procédés scientifiques empécher une attaque avec des armes bctériologiques, la seule chose à faire est de tenter de limiter la catastrophe.

Une organisation d'hygiène et de lutte contre les maladies infectieuses, minutieusement étudiée, donnera seule quelque chance de réussite.

On peut envisager schématiquement comme suit cette organisation: division du pays en secteurs sanitaires pouvant éventuellement être totalement séparés les uns des autres, Installations hospitalières

Figure A.175: U.S. intelligence reports on apparent large-scale offensive biological warfare preparations in Germany [Princeton University Library, Allen Dulles Papers, Series 4, Subseries 4K: Telegrams d'etat, 1942–1945, 1944 May-July 15, MC019.09_c46.pdf, https://findingaids.princeton.edu/catalog/MC019-09_c46].



suffisantes,laboratoires de diagnostic fixes ou mobiles, stockage de vaccins ,de sérums et de médicaments,stockages de milieux de culture,de produits biologiques permettant les diagnostics,affectatition de médecins et de bactériologistes à des secteurs déterminés.
Plus ~~xxxx~~ l'organisation d'hygiène aura été minutieusement prévue plus vite elle pourra se mettre en route ,plus les chances de succès seront grandes.

L'organisation d'hygiène devra être doublée d'une organisation de police et d'une organisation économique(stockage de matières alimentaires),Les secteurs sanitaires en effet devront être probablement complétement séparés les uns des autres en cas de maladie à grand génie épidémique(peste pulmonaire par exemple) et aucun habitant ~~dx~~ d'une zone infectée ne devra se rendre dans une zone saine et inversement.

#254. TOLEDO. For 154 from 687.
In reference to your Toledo message.

According to a report from Bahr last week, he has a Dutch informant working in the underground who was aware of the existence of "thousands" of rats inside Denmark. The plan was to infect them with typhus at a later date. Bahr furnished us the foregoing information with no solicitation from us.

Months ago our British friends were given various reports like the above but in the course of the last 2 or 3 months they have ceased to be interested and apparently they take the view that the Germans have carried on some sort of experiments with rats but that it does not amount to a large scale project.

We have requested both the Poles and the British to give us any particulars they may have on hand. Meanwhile, London should be able to supply previous British reports on this subject.

#689. TOLEDO. Action: Washington;
Information: London, Algiers.

The material below is dated the 16th of last month and is evaluated F-0. Source of information is third ZZUZU chain agent 105. In connection with germ warfare, a Nazi doctor in Lyon is reported to have made the following statements: preparations for this type of warfare are practically complete. Both animals and people have been subjected to tests. A type of diphtheria microbe has been found which neither sera nor vaccines can counteract. The disease is transmitted with great speed; (from 2-3 days); it is extremely tenacious, and can be spread with great facility, even by bombs*. At present, studies are being made which include efforts to discover the length of time it will take before an infected area becomes habitable. The virus noted in Sweden is difficult to isolate and it brings about a practically overwhelming intoxication of the human organism. The Germans have not yet been able to apply the latter.

*Received as BOSBS.

At this writing, additional advices concerning the matters herein enumerated would be of great aid to us.

1. Consult your cables #3418-22 and #3152-3. With reference to the glass factory at St. Gobain at Chauny, we would like to know the amount of damage caused by the bombing of this place or the details about the construction of special glass receptacles.

2. Consult your cable #3215, because of the importance of this matter, we should like additional information of a later date than contained in your cable #3643, if at all possible. We particularly would like to know the name of the top scientist at the Weimar Brewery, the new material produced during the last 3 months, and whether it has been bombed.

3. Please forward any knowledge you have concerning the 25 features set forth in our cable #1083 and all subsequent cables referring to said matter. It would be of great aid to have knowledge of relevant scientists and their whereabouts.

Donovan to Deane. TOLEDO. Action: Moscow. Information copies:
Glavin, Caserta and Bruce, London.

Typhus is mentioned in a Pittsburgh Press story dated the 28th of October from Moscow and in a dispatch in the New York Times from Moscow dated the 30th of April. The latter release is thought to have been sent out only as an experiment. Following is a resume of the article in the Pittsburgh Press:

bombs

Typhus capsules placed in light fragementation bombs along with high explosives have been dropped from Nazi planes over Turciansky Svaty, Martin, Ban Bystrica and other insurgent villages in the lower Tatra Mountains in Slovakia. There is as yet no widespread epidemic but signs have been put up by Partisans warning people to apply a calcuim mixture or to burn clothing or any other material which has come in contact with the serum.

There has been no substantiation of this story from any source, and the story may be propaganda or merely heresay. However, if there is truth in these reports, the information becomes significant. Please question General Fitin for any further information and ask him if these articles are correct or if they are probable. Please secure a sample of the capsule, if you can.

CS/ 918 - Soldat FLAUDER (Feldwerkstatt 511) Captured THEDING 3 Dec 44
CS/1516 - Gefreiter MICHALSKI (Inf. Ers. Bn 588) Captured KALDENKIRCHEN 1 Mar 45
LD/ 420 - Unteroffizier ZERLAUTH (5 FSJ Div. Stab) Captured SCHLEIF 11 Jan 45

Information received: 9 Mar 45

TRANSLATION

MICHALSKI : I worked on the new jet-turbine.

ZERLAUTH : Did you construct turbines for V-weapons?

MICHALSKI : No. We constructed a jet-turbine. JUNKERS stabted it. It is the smae one which UDET had when he broke his neck. This new turbine can only be started up from outside. Afterwards we constructed a turbine-driven compressor with the engine system, and that's what the present turbine-fighter has.

ZERLAUTH : 'Schrammel'-turbine?

MICHALSKI : No, the "Schrammel' is a different one again.

---------oOl----------

MICHALSKI : How far have they advanced with splitting the atom? Certainly up to date you can split it 98%, up to 98 parts. I know experiments were being carried out at the Kaiser Wilhelm Institute in BERLIN.

ZERLAUTH : At HEIDELBERG too, I know that.

MICHALSKI : It's nonsense - it won't do any good. However, they're sure to use microbe-bombs!

ZERLAUTH : There's no need for that, typhus has already broken out near COLOGNE!

MICHALSKI : Yes, but not caused by our stuff. Typhus isn't so bad, but they're usually filled with leprosy and plague which is a different proposition. It's quite obvious that epidemics can break out wherever that stuff is dropped. That would be the vilest thing we could do.

ZERLAUTH : How do you know that bombs like that have been filled?

MICHALSKI : Because I have loaded them myself - at any rate watched them being loaded. They were taken to CENTRAL GERMANY from TORGAU, at any rate they were transported via TORGAU. I don't know how they're filled, but I do know they exist.

19 March 1945

MEMORANDUM FOR SCIENTIFIC BRANCH:
(ATTN: Captain Baker)

SUBJECT: German Bacterial Bombs. Extracted from SRM 1246, 10 March 1945.

Presumably referring to some kind of bacterial bomb, a German Pfc. P/W of Infantry Replacement Battalion 588, captured at KALDENKIRCHEN 1 March 1945, asserts that these bombs are packed in square cases with a "special red line" around them. He does not know if the cases are padded on the inside but they can and are moved by transport. He states that the cases are not marked with the word "PEST" (plague) but the cases are numbered and are never allowed in contact with other things. He does not know where they are filled and where they come from, but definitely asserts that they are loaded at TORGAU.

The bombs have just sufficient explosive effect to shatter the casing which is already grooved. They are divided into four parts so that only a slight explosion is needed for the groove to give way and the bombs fall apart on impact with the ground. Glass containers are fitted tightly into the bombs. These containers are filled, P/W thinks, in a laboratory and then inserted into the bombs. He also mentions "some sort of rubber" which is specially fitted inside the bombs. (Ed's Comment: Presumably around the glass containers.)

P/W presumes that the microbes multiply and have their "NÄHRBODEN" (culture medium) inside the container.

The people who were engaged in the preparation and handling of these bombs were not allowed to know their contents or to talk about them, but P/W states that "an inkling of what was in them leaked out".

While P/W's information on this subject goes back to March or April 1944, he thinks the bombs have not been used because Hilter is saving them "for the end".

BW INFORMATION

SOURCE: Military Intelligence Division Report #R-169-45, from M/A Stockholm, MIS No 129528, dated 8 March 1945, subject: "Bacteriological Warfare, Denmark."

Report from STOCKHOLM, rated B-3, concerning a possible Bacteriological Warfare experimental station in Demark. Information is dated late January 1945.

a. From two to three hundred rats and mice arrive daily from Germany by ship at SÖNDERBORG (Sondorborg) (54° 55'N, 9° 47'E). They are then sent to the experimental station at HÖRUP HAV (54° 54' 30"N, 9° 53'E). Large wooden cases also arrive every day, but it is not known what they contain.

b. The prohibited zone around the station has been extended to include the surrounding area, and it is forbidden to enter without a special pass. New barracks are being built at the station and the personnel employed there are being confined to the station territory. Engineers who formerly stayed at the Baltic Hotel are also being quartered at the station.

Nazi Underground Leaders Captured. ***San Bernardino Sun.*** **24 February 1947 p. 1 [https://cdnc.ucr.edu/cgi-bin/cdnc?a=d&d=SBS19470224.1.1]**

Nazi Underground Leaders Captured

Bacteria Weapon Reported Found in Group's Hands

BERLIN, Feb. 23 (AP) American and British troops cracked down today on a widespread Nazi underground movement which claimed possession of a secret bacteriological weapon to turn against the occupying powers. A former colonel in the German army section that worked on war-with-germs projects was among the "hundreds" seized.

It was the biggest push against the underground since the war ended, and the first on a bizonal scale.

Authorities said they had not learned definitely whether the group actually possessed a bacteriological weapon. Lt. Gen. Lucius D. Clay reported American authorities did not consider the movement "particularly dangerous," while a British spokesman said it was "silly and pretentious" but could not be allowed to spread.

Moving swiftly over ice-glazed roads and in a snowstorm, soldiers and intelligence agents picked up a number of former high ranking officers in the SS (elite guard) and other Nazi organizations. The Americans reported the arrest of about 30 suspects in their zone but said most of the raids were in British Germany. There authorities said hundreds of persons were seized by "thousands" of allied troops in what was described as "Operation Selection Board." With arrests continuing, they disclosed no specific totals.

'WAR' IN RUSSIA

British officials said the movement had tentacles in the Soviet and French zones, and that its aims included restoration of German militarism and a Nazi dictatorship "in order to lead the nations of Europe against Russia." The Russians and French were kept informed of the progress of the raids.

Among those arrested in the American zone were former SS Major Gen. Kurt Ellerick, Hitler Youth Col. Walter Shimmelpfeng, Army Major Felix Buck, SS Major Martin Zinzt, SA (Storm Troops) Major Fridolin Becker, SS Capts. Ernst Berndt, Siegfried Bettke and Werner Roepke, and SS Lts. Hans Pavel and Hans Becker. Some were connected with other military men seized on similar charges in the past three months, officials said.

GERM EXPERT CAUGHT

The British nabbed Col. Hans Eismann, former officer of the bacteriological warfare division, who had been living under an assumed name; Col. Heinz Kling, former SS officer who headed a tank regiment at the end of the war; Dr. Rolf Wilkenning, SS officer described as an important member of the former German intelligence service and founder of the Koelner Kreis, prewar group used by German intelligence for pre-invasion penetration of the Low countries.

S.D. 4701/MIS-926445 [NARA RG 319, Entry NM3-85M, Box 62, Folder 926445].

U.S. War Department General Staff, Intelligence Division. 29 January 1947. German Production of Biological Warfare Agents.

1. The Intelligence Division has a specific requirement for the following:

Reference is made to a broadcast in German from Moscow to Europe, 15 January 1947, 9:00 a.m. EST., commentary by Kubanin, "The Nuremberg Trial of Nazi Doctors." The following is quoted from a summary of this broadcast:

"Their (German) experiments had been designed to promote the scientific development of the methods for killing people by the million. Thus the liberating Red Army had found at Poznan a German factory manufacturing lethal bacteria on a mass scale."

Latest information in I.D. indicates that the German project at Posen, Poland, had not begun operations for the production of biological warfare agents although construction had been completed.

The following information is requested:

a. Who's Who information concerning Kubanin.

b. Any information available on Russian knowledge of German BW with particular reference to the installation at Posen, Poland.

c. What is the present condition of the installation at Posen and for what purposes is it being used, if any?

d. Is there any other evidence concerning the manufacture of bacteria at the Posen installation by the Germans?

2. To assist in satisfying this requirement, the following collection guidance is submitted for consideration.

The installation at Posen, Poland, is referred to in German intelligence documents as the "Nesselstedt Project."

3. As complete an answer to the requirement, as may be procurable, must be received in the Intelligence Division on or before 1 Apr. '47. [...]

4. Specific reference should be made to Control No. S-629 in all replies to this requirement. [...]

Office of the Assistant Chief of Staff, G-2, Headquarters, United States Forces, European Theatre, to Director of Intelligence, War Department General Staff. 12 March 1947.

No information is available in this headquarters at the present time pertaining to the request made in basic communication, Control No. S-629. Any subsequent information will be forwarded. [...]

A.4 Chemical Warfare

A.4.1 German Chemical Weapons

[Scientists in the Third Reich produced and tested a wide variety of organophosphate nerve agents, and created several especially potent ones (which were given postwar codenames beginning with G for German): tabun (GA), sarin (GB), soman (GD), ethylsarin (GE), cyclosarin (GF), and isopentylsarin (GH). (The code name GC was not used, to avoid confusion with the U.S. code name for phosgene, CG [Tucker 2006, p. 105]. GG was likely skipped because of the double letters.) These agents were exclusively possessed by the Third Reich and were stockpiled but never used, due to fear that Allied nations would retaliate with much cruder but still effective first-generation chemical weapons such as mustard gas (which had also originally been created by German scientists). The G-series nerve agents and information on how to produce them was removed from Germany at the end of the war, and G-series agents have been mass-produced by a wide range of nations ever since.]

BIOS 542. *Interrogation of Certain German Personalities Connected with Chemical Warfare.*

PROFESSOR DR. RICHARD KUHN

(interrogated on 1–2 April 1946, at the K.W.I, Heidelberg)

[...] Pinacolyl alcohol gave compound 25075, SOMAN, which proved to be even more potent and which has not, in fact, been surpassed so far. It was first prepared in the early spring of 1944.

To assist in the evaluation of these compounds as they were prepared, KUHN's team used a test based on the relative inhibition of choline esterase by the candidate agent, compared to that caused by a standard agent in the methane-phosphonic ester series; in the later stages of the work compound 15146, SARIN, was used as the reference standard. Wa Prüf 9 were in the habit of sending to KUHN compounds prepared in other laboratories for screening in this fashion; of these compounds sent in from the outside, the SARIN-SOMAN analogue prepared with diethyl carbinol by HÜCKEL was the most active, being but little less active than SOMAN itself.

Meanwhile, the general problem of the mechanism of action and pharmacological properties of the TABUN (15083)–SARIN–SOMAN series was being tackled by the various members of the KUHN team[...]

x Code numbers commencing with 25001 represent substances prepared by KUHN; 21001 by HÜCKEL, and 14001 and 15001 by I.G.

KUHN's work in this field was abruptly terminated by the HWA in September 1944, when they carried off all relevant documents and demanded the destruction of all laboratory notebooks, etc. The complete set of these documents was stated by KUHN to have been buried in a mine shaft at RÜDESDORF, ten miles east of BERLIN, either in the same shaft as that used for burying the library of the German Chemical Society from the HOFFMANHAUS, or in one adjacent to it. Some months ago, KUHN was informed by Dr. PFLÜCKE of KASTANIEN ALLE 35, POTSDAM, that the entire contents of these shafts, presumably including the KUHN reports, were carried off by Prof. Col. KARGIN to the KARPOV INSTITUTE in MOSCOW. [...]

KUHN also stated that, in accordance with the usual German practice, he was not in contact with any other workers in the C.W. field, that he did not know the names of any such workers, and that in particular he knew nothing of SCHRADER's work. The last of these statements is almost certainly true, for it was clear from one of his last remarks that he believed that iso propyl fluorophosphate had never been prepared (he recommended its examination) whereas in fact SCHRADER has described several ways of making it. [...]

[The above report, BIOS 542, stated that "the usual German practice" for secret military programs such as nerve agent development was for individual scientists to know only their part of the program, not other parts of the program or even other scientists who were working in those other parts. That highly compartmentalized approach would also have been employed in the German nuclear program (Appendix D).

BIOS 542 also showed that at least three different groups—Richard Kuhn's group, Gerhard Schrader's group at I.G. Farben Leverkusen, and Erich Hückel's group—were independently synthesizing large numbers of novel nerve agents.

Finally, BIOS 542 revealed that all of Kuhn's information on nerve agent synthesis, and perhaps all of the information for the entire German nerve agent program, was captured and utilized by the Soviet Union.]

[A significant innovation in nerve agents first became publicly known after the war (see molecular diagrams on p. 569). Although G-series agents were relatively small molecules that dispersed fairly rapidly, if they were coupled to an oily hydrocarbon chain, they could persist on surfaces for long periods of time and also readily penetrate through human skin. These improved nerve agents became known as the V-series (for venomous); VX was the favorite in the United States and United Kingdom, and the similarly acting VR was the favorite in the Soviet Union.

There are a number of reasons to suspect that the key innovation for the V-series may have been a wartime German creation:

- Nearly three decades earlier, German scientists pioneered the method of linking a toxic agent to an oily hydrocarbon chain in order to make the agent persist much longer in the environment and to make the agent readily penetrate through human skin. That was the key to mustard agent, by far their most successful previous chemical weapon.

- Beginning in 1943, the slow but inexorable Soviet push westward led Germany to further accelerate its already well-funded and advanced scientific research and development programs, in order to find military methods of countering the Soviet forces. Making the most toxic German chemical agents persist much longer in the environment, so that they could be used to contaminate areas and block a Soviet advance (see p. 2633 for such plans), would be a very obvious and very high-priority goal.

- After the war, Gerhard Schrader, Ernst Schegk, and Hanshelmut Schlör of Bayer in Leverkusen (part of I.G. Farben during the war) filed patents on linking an oily hydrocarbon chain to a toxic organophosphate molecular structure (see Figs. A.211–A.214 for examples), although postwar restrictions both delayed public acknowledgement of that work and compelled them to focus on insecticide applications instead of chemical warfare applications.

- After the war, V-series agents were not invented by one clearly defined Allied scientist or group. Rather, they appeared almost simultaneously from several apparently independent groups, making it seem more likely that they were based on wartime German work that had been disseminated to all of those groups. In 1952, Ranajit Ghosh and J. F. Newman at the UK Imperial Chemical Industries (ICI) Plant Protection Laboratory produced a potent V-series agent, Amiton, that had been intended as an insecticide. Almost simultaneously, Lars-Erik Tammelin of the Swedish Institute of Chemical Defense produced similar compounds that came to be known as Tammelin esters. The United States began producing VX, and the Soviet Union began producing VR.

- German experts such as Friedrich Wilhelm Hoffmann were employed after the war to mass produce V-series agents. Hoffmann was also deeply involved in the postwar U.S. development (or perhaps the postwar transfer/recapitulation of wartime German work) of the Agent Orange defoliant, dioxin, various other toxins, attempts to harness LSD, and other chemical agents.[6]

Patentiert im Gebiet der Bundesrepublik Deutschland vom 11. Oktober 1949 an
Patenterteilung bekanntgemacht am 23. August 1951

Es wurde gefunden, daß sich neutrale Ester der Thiolphosphorsäure folgender Zusammensetzung

(R_1 und R_2 stehen für beliebige Alkylreste, R_3 steht für einen beliebig substituierten Arylrest) hervorragend zur Bekämpfung von saugenden und fressenden Insekten aller Art eignen. Die genannten Ester sind z. B. durch Umsetzung von Dialkoxyphosphorsäurechloriden mit Thiophenolen nach an sich bekanntem Verfahren erhältlich.

Die neuen Ester können als Staub oder, vermischt mit einem Emulgator und Wasser, als Emulsionen zur Anwendung gebracht werden. Folgende Beispiele mögen das Gebiet der Erfindung erläutern:

Beispiele

1. Junge Apfelbäumchen, die von Blattläusen befallen sind, werden mit einer wäßrigen Lösung bespritzt, die 0,005% folgender Verbindung

(Kp. 1,5 mm/148°)

enthält. Bereits nach 3 Stunden beginnen die Blattläuse abzufallen. Nach 5 bis 6 Stunden sind alle Blattläuse abgetötet.

2. Petrischalen werden mit einem Staub einge-

Verfahren zur Herstellung von neutralen Estern der Thiophosphorsäure

Patentiert im Gebiet der Bundesrepublik Deutschland vom 8. Mai 1949 an
Patenterteilung bekanntgemacht am 6. September 1951

Es ist bekannt, daß sich Salze der Thiophosphorsäureester folgender Konstitution:

$$\begin{matrix} RO & & O \\ & P & \!\!-\, S - Me \\ RO & & \end{matrix}$$

mit Alkylhalogeniden zu den entsprechenden neutralen Estern umsetzen lassen. In vielen Fällen führt dieses Verfahren aber nur dann zum Ziel, wenn als Salze die der Schwermetalle, wie Blei oder Silber, und als Alkylhalogenide die Jodide gewählt werden. Es wurde nun gefunden, daß sich die neutralen Ester der Thiophosphorsäure leicht herstellen lassen, wenn beliebige Alkylrhodanide, die im Alkylrest in beliebiger Weise substituiert sein können, mit den technisch leicht herstellbaren Alkalisalzen der Dialkylphosphite zur Umsetzung gebracht werden. Unter Abspaltung von Alkalicyanid bilden sich die gewünschten Ester. Es war nicht vorauszusehen, daß die Reaktion diesen Verlauf nehmen würde. Das Schema der Reaktion ist folgendes:

$$\begin{matrix} RO & & O \\ & P & \!\!-\, Na + CNS \cdot R \\ RO & & \end{matrix} \longrightarrow \begin{matrix} RO & & O \\ & P & \!\!-\, S - R + NaCN\,. \\ RO & & \end{matrix}$$

Die Alkylreste R können gleich oder verschieden sein. Es lassen sich nach dem neuen Verfahren Verbindungen herstellen, die sich durch stärkste kontaktinsektizide Wirkungen auszeichnen. An folgenden Beispielen soll das Wesen der neuen Reaktion erläutert werden.

Verfahren zur Herstellung von Thiopyrophosphorsäureestern

Patentiert im Gebiet der Bundesrepublik Deutschland vom 7. September 1949 an
Patenterteilung bekanntgemacht am 20. September 1951

Es wurde gefunden, daß sich Thiopyrophosphorsäureester folgender Zusammensetzung:

$$\begin{matrix}R_1O\\R_2O\end{matrix}\!>\!\overset{\overset{O}{\|}}{P}-S-\overset{\overset{O}{\|}}{P}\!<\!\begin{matrix}OR_3\\OR_4\end{matrix}$$

(R_1 bis R_4 können gleiche oder verschiedene Alkylreste sein), die bisher noch nicht bekanntgeworden sind, in technisch guter Ausbeute durch Umsetzung von Dialkylphosphiten mit Schwefeldichlorid oder dem durch eine sekundäre Base substituierten Schwefeldichlorid, den Dialkylaminosulfensäurechloriden herstellen lassen. Bei der Umsetzung wird im ersten Falle Salzsäure frei, die zweckmäßig durch Zugabe eines Säurebindemittels, z. B. Pyridin, Dimethylanilin u. a., gebunden werden kann. Im zweiten Fall wird die entstehende Salzsäure durch das gleichzeitige entstehende Dialkylamin gebunden. Die Umsetzung vollzieht sich nach folgenden beispielsweise angeführten Gleichungen:

$$SCl_2 + 2\,(C_2H_5O)_2\cdot\overset{\overset{O}{\|}}{P}-H \longrightarrow \quad (1)$$

$$(C_2H_5O)_2\cdot\overset{\overset{O}{\|}}{P}-S-\overset{\overset{O}{\|}}{P}(OC_2H_5)_2 + 2\,HCl$$

bzw.

$$(CH_3)_2\cdot N\cdot SCl + 2\,(C_2H_5O)_2\cdot\overset{\overset{O}{\|}}{P}-H \longrightarrow \quad (2)$$

$$(C_2H_5O)_2\cdot\overset{\overset{O}{\|}}{P}-S-\overset{\overset{O}{\|}}{P}(OC_2H_5)_2 + (CH_3)_2NH\cdot HCl.$$

Verfahren zur Herstellung von insekticid wirksamen O,O-Dialkyl-S-phenyl-thiono-thiolphosphorsäureestern

Anmelder:
Farbenfabriken Bayer Aktiengesellschaft,
Leverkusen-Bayerwerk

Dr. Ernst Schegk, Wuppertal-Elberfeld,
und Dr. Gerhard Schrader, Wuppertal-Cronenberg,
sind als Erfinder genannt worden

1

Es wurde gefunden, daß man insekticid wirksame O,O-Dialkyl-S-phenyl-thiono-thiolphosphorsäureester durch Umsetzung von Dialkylthionophosphorsäurechloriden mit substituierten Phenylmercaptanen dadurch herstellen kann, daß als substituierte Phenylmercaptane Nitrophenylmercaptane, die gegebenenfalls im Phenylrest durch Halogen oder Alkylreste weitersubstituiert sind, verwendet werden.

Die neuen Thionothiolphosphate zeichnen sich durch hohe Beständigkeit gegen hydrolytische Einflüsse und durch sehr gute kontaktinsekticide Wirkungen aus. Gegenüber den vergleichbaren Thiolphosphorsäureestern, die z. B. aus der deutschen Patentschrift 817 753 bekannt sind, zeigen die neuen Thiono-thiolphosphorsäureester eine wesentlich geringere Toxizität gegenüber Warmblütern.

Außerdem sind die erfindungsgemäßen Verbindungen auch den aus der deutschen Patentschrift 885 176 her bekannten Verbindungen überlegen, und zwar sowohl hinsichtlich der Toxizität als auch hinsichtlich einer besseren Wirksamkeit. Aus der folgenden Gegenüberstellung sind diese Tatsachen zu ersehen:

Verglichen wurden der erfindungsgemäße Dithiophosphorsäureester

BIOS 714. *The Development of New Insecticides and Chemical Warfare Agents*

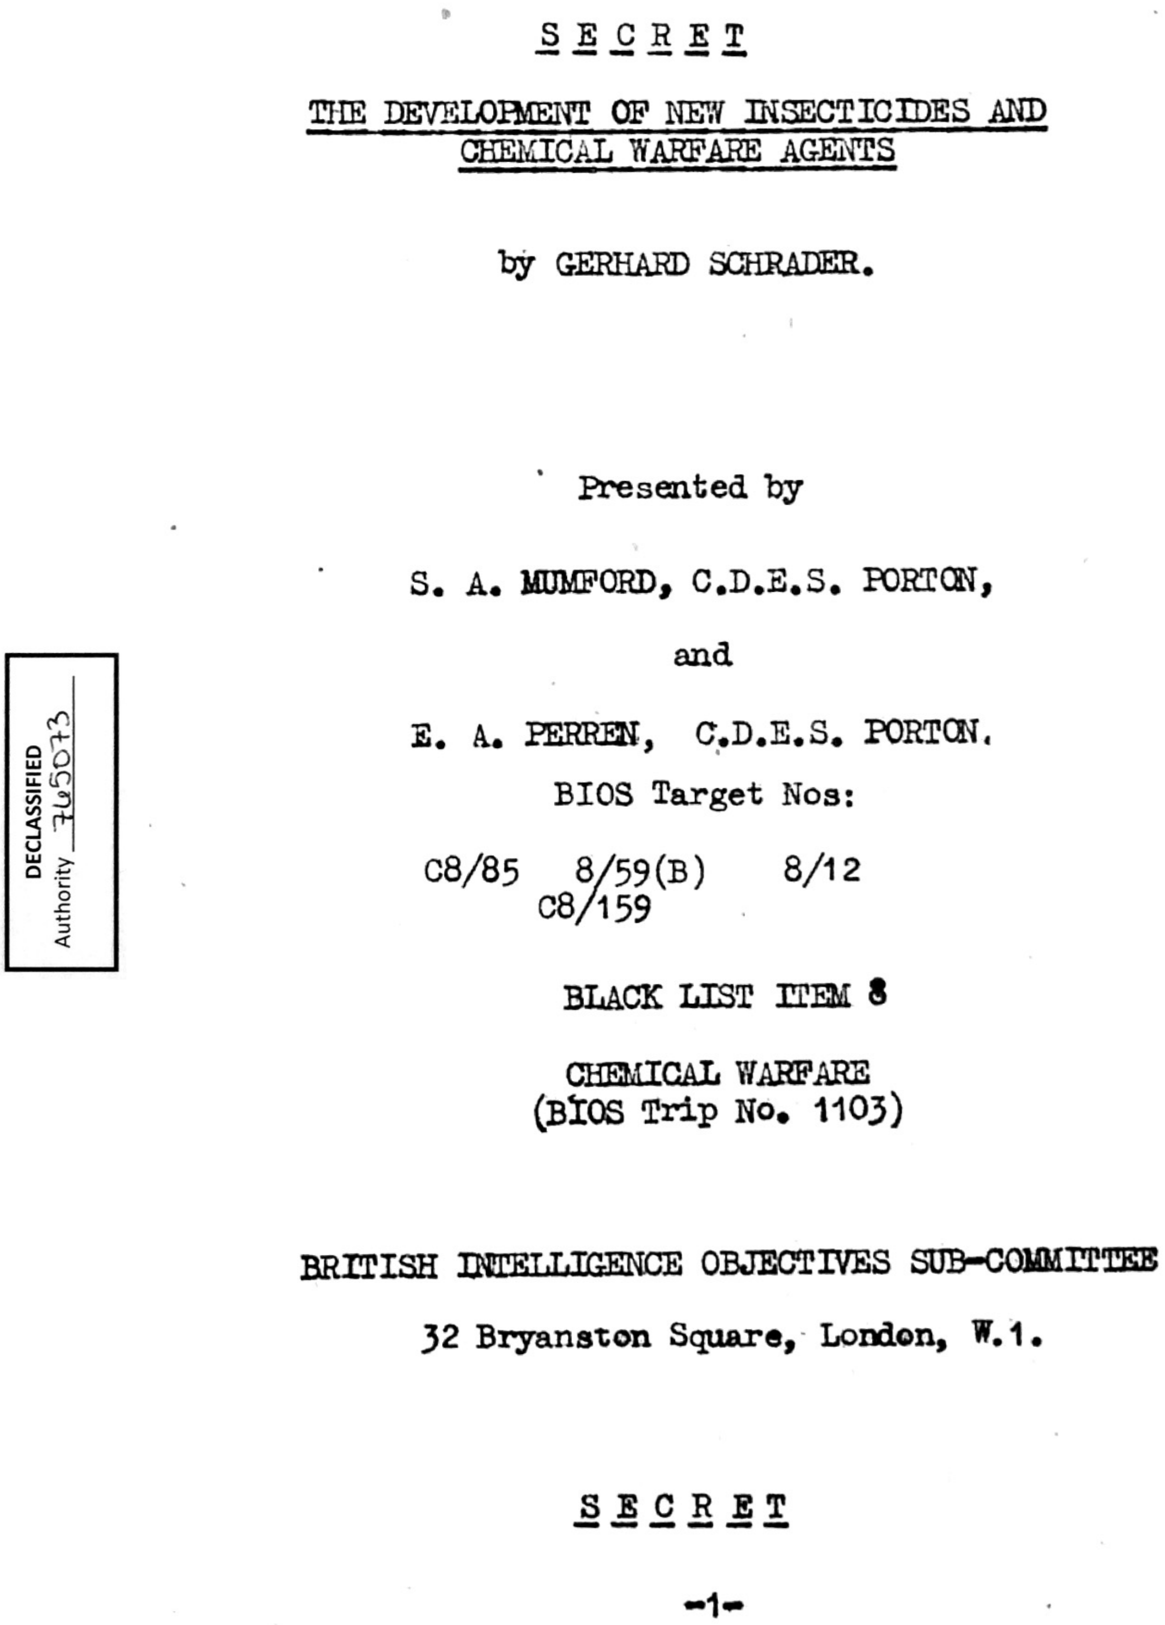
[Please see photographs of selected pages of this report in Figs. A.215–A.238.

This report demonstrates that Gerhard Schrader did in fact develop and test a wide variety of V-series nerve agents during the war. While being imprisoned and interrogated by Allied forces at Dustbin (see p. 2126) after the war, Schrader wrote several reports such as this that recounted his wartime experiments and results. Many of Schrader's agents listed in BIOS 714 possessed the same key molecular features as VX and VR, such as using a nitrogen atom to attach two branches of hydrocarbons to the toxic part of the molecule. Very unusually for this report series, the BIOS 714 report was issued in two versions, an original edition and a heavily censored "revised" edition that omitted all of the V-series agents and was less than half as long.

It seems likely that there are other important reports about these V-series agents from Schrader, or perhaps even reports about additional V-series agents that Schrader may have invented and tested. It is also quite possible that other scientists such as Richard Kuhn, Erich Hückel, Friedrich Wilhelm Hoffmann, or Otto Ambros developed further V-series agents in Germany during the war.

The personal interrogations of Schrader and other German-speaking scientists by Allied chemists, reports such as the uncensored original edition of BIOS 714, and other German information captured by the Allies most likely led to the postwar production of V-series agents in the United States and other countries. Much more archival research is needed to clarify the history of the development and dissemination of knowledge about V-series agents.

For Gerhard Schrader's original German manuscript of this report, as well as other related information, see NARA RG 319, Entry A1-134B, Box 693, Folders XE171240 Gerhard Schrader (six folders).]



SECRET

THE DEVELOPMENT OF NEW INSECTICIDES AND CHEMICAL WARFARE AGENTS

Preface

In August - September, 1945, an investigating team interviewed, amongst others at Kransberg-Dustbin, Dr. Gerhard Schrader, a research chemist, late of the I.G. Works Elberfeld. A brief account was obtained of the history of his important series of researches on organic fluorine and phosphorus compounds, embracing the discovery of the nerve gases Tabun and Sarin, and of a number of potent insecticides. This account is included in B.I.O.S. Final Report No.44, Item No.8.

At the conclusion of the interrogation, the team requested Dr. Schrader to prepare a fuller account of this work, including preparative details, his ideas on the relationship between chemical constitution and toxicity towards insdcts and warm-blooded animals, and his suggestions for future work. In response to this request several voluminous reports, in part overlapping have been received. Dr. Schrader has been handicapped in writing these by the destruction or inaccessibility of his records and notes, so that there are certain gaps, especially in the insecticidal data and the preparative methods. Despite this it has been possible after translation to piece together a coherent account of his work.

Fortunately several files have come to light containing what appear to be the results of sorting tests for toxic effect against aphids of a large number of the substances listed in Schraders papers. These results have been inserted in the Appendices. Some compounds are mentioned several times in these files and occasionally different figures are quoted for the insecticidal activity of the same compound. Where this is so, the higher activity has been included in this report.

Details of the sorting test used by the entomologist working with Schrader have not been found.

The very fact that details are nowhere given is however evidence that it was a standard routine test and for this reason the results can be accepted as giving a good indication of comparative toxicity.

SECRET WEAPONS Snafu (out)

Sept. 4, 1944.	Source K-13 reports Aug 17 Arditi detachment San Marco Div issued following new weapon. Twenty special tubes shoot gas bombs about 35 kg each, exploding a dense smoke smelling of chlorine and consisting of a substance which destroys oxygen within 250 meters. 15 minutes after smoke let loose it burns with a light green color and all objects soaked with this substance also set on fire. Reported that neutralizing substance to this new means is ammoniac. Exercises this weapon carried on near Pontedecimo 300 meters from Church of Madonna di Livellato. (1074)

MFIU No 1, 13 March 45

PW Intelligence Bulletin No 1/47

Desperation Warfare

13. Chemical Warfare

Statements of Intention

A CWS officer stated (Dec 44) that Germany has enough planes specifically held in reserve for gas warfare.

PW confirms previous information that the classification of secret has been removed from the new filter (42 and/or OC, issued Summer 44) and that some men in his coy carried them.

CWS officer, Lt LANGE, told PW that he expected the war to be over by end of April, and that Germany would resort to gas during the last few days.

(Source: Uffz ZACHARIASZ 8 Coy 941 Regt captured 6 March vic RUSSDORF)

PW overheard Obst WAENTIG, OC 3 Para Arty Regt and his adjutant, Lt STEINBECK, say that "the new weapon is chemical warfare". Special gas could be dropped by plane, by ground forces or by Arty. Some doubt was expressed as to whether these measures could be taken in time.

(Source: Gefr Parvel LICHOTA (Pole) HQ 3 Para Art Regt captured 8 March vic GOTTESBERG)

Gas Trng Courses

BONN. PW was sent with 16 others from 1 Bn 748 Regt to a gas school in BONN (Dec 44). The course (appr 4 weeks) was given to 145 men. The course included gas mask drill. A man was formerly required to put on his mask in 17 seconds. This has now been reduced to 7 seconds because the Allies require that length of time. Movements while wearing mask were considered too slow, therefore students were required to wear the mask 2 hrs daily while doing usual work.

All gases were explained, including "Bura" an improved type of mustard. (S.I.R. 1228)

It was pointed out that, since the Allies have not been able to beat Germany with weapons, they would resort to gas. Therefore it was absolutely necessary to make all preparations.

Students were shown all caliber Arty shells filled with gas. The lower part of such shells was marked with a white or yellow 3 cm wide band. Formerly the stripe was painted in various colors on the nose. White is for throat irritant (Rachenreitzende Kampfstoffe), yellow is for vesicant.

First aid and protective measures were taught.

(Source: Uffz ZACHARIASZ 8 Coy 941 Regt captured 6 March vic RUSSDORF)

DOBERITZ. PW took an 8-day gas course at DOBERITZ, Dec 18-23. One man at a time from each coy in his unit (4 Pz Aufkl Ers u Ausb Bn) took the course. 70 men from various units were trained as gas NCOs. They were told that every German soldier should be familiar with defense against chemical warfare, and that it could be expected that gas would be used (men were never told by whom).

(Source: Gefr Antoine RUNSER 103 Pz Aufkl Bn captured 6 March vic KOLN)

13. Chemical Warfare (Continued)

SUCHTEL. PW from 1190 Feld Ers Bn states that appr 8 Jan, 10 men from his coy were sent to a special 5-day gas course in SUCHTEL (nr VIERSEN). Course was attended by appr 60 EM from various (mainly Para) units. They were told that gas warfare was a possibility. All gases were explained. A US mixture of all gases was described as especially dangerous. Bombs, Arty shells, and plane sprays were mentioned as possible means for spreading gas. Course included instructions in the usual first aid measures. PW states that the soldiers were surprised at the sudden emphasis on gas discipline.

(Source: Kan Willy REITENBUCHER 1190 Feld Ers Bn captured 3 March vic GELDERN)

Refresher Courses

2 men from each coy of 1224 VG Regt were sent to VOSSUM to take a gas refresher course 6 Jan. No new gases were mentioned. Filters of regt were exchanged for "filter 41". Losantine tablets were exchanged for a liquid in an orange bottle. PW thinks it is losantine in liquid form.

(Source: Uffz Otto GARBE HQ coy 1224 Gren-Regt captured 5 March vic RHEINBERG and one other)

A continuous 8-day course in chemical warfare was given to all coys of 89 VG Div. 2 men at a time from each coy rotated in taking the course. The first series of lectures began Nov 44, the second series continued until beginning of Feb 45. Personnel was required to carry gas masks even when not on duty.

(Source: O/Gefr Hans WELTER 2 Coy 1052 Gren Regt captured 4 March vic KREFELD)

Decontamination Pls

PW was in a decontamination pl of 40 men. Unit was used for delousing, for litter carrying, and was finally split up. PW states there was little gas consciousness in the unit. All decontamination equipment was sent E of Rhine middle of Feb.

(Source: O/Gefr Johann ZIERMAIER 1 Coy 990 VG Regt captured 6 March vic SCHLEIDEN)

Decontamination Pl of 189 Med Coy was formed in May 44. It had 1 Unterarzt, 4 NCOs, and 45 EM. In Dec 44 all gases, including those affecting nerves and blood stream, were explained. The German gas mask was described as adequate protection against all gases except carbon monoxide. The usual first aid measures were taught. Coy had 1 Heeresatmer to be used only in emergency.

(Source: O/Gefr Ludwig RIEDINGER 8 Coy 1055 Inf Regt, captured 4 March vic GEMUND)

Gas Shell Firing

While training in MUNSTERLAGER in July 44 selected crews from 13 Art Ers Abt fired gas shells (cal 10.5 and 15 cm). Men did not wear any protective clothing, but had their gas masks ready for instant use. Shells semmed to contain a liquid. They were perforated. Holes were lightly sealed.

Poison Gas Production

PW heard from his uncle, who works in an underground factory N of NURNBERG, that 10,000 workers are employed there in the production of gases, including a new type able to penetrate any known gas mask. Gas is stored there in huge quantities.

Research in atom smashing had been successful (June 44), and PW's uncle claimed a new atom-smashing weapon would be ready for use within a yr. Other experiments are being conducted at TORGAU (where according to the uncle, political prisoners are used as guinea pigs) and in the BERLIN-SPANDAU citadel.

PW claims that other gas production plants are at REGENSBURG, in the Spessart forest, and an underground plant near a small health resort vic the source of the DANUBE.

(Source: San Uffz Theodor GORGES 4 San Bereitschaft Hermann GORING Fallsch Corps captured 1 March 45)

Gas Bomb Depot

A Gas bomb depot is located (5 Nov) in FORST HOHENBUCKO in a rectangular area extending along rd HOHENBUCKO-WUSTERMARK from GSGS 4416/P8/989708 to 014725 and extending appr 1¼ km NW. Bombs are stored in bunkers aboveground, covered with appr 30 cm of concrete, 1.20 m of earth, and camouflaged with small trees. Each bunker contains five hundred-fifty 500 lb bombs or two hundred-seventy-five 1,000 lb bombs. F-3

9 barracks, appr 100 m NW of rd and easily seen from the air, house administration offices and living quarters for 360 workers (200 women including 80 Ukranians).

(Source: Uffz Rudolph SCHWARZ 3 Pz Gren Div captured 6 March vic VOLLBERG)

Transport of Gas Shells

PW was in a Transport Begleit Coy zbV in Poland until Aug 44. The unit evacuated gas bombs to the rear. PW insists it handled 60,000 (!) shells which required 48 trains of 30 cars each. Each train hauled a minimum of 1080 and a maximum of 1500. 10 trainloads were shipped to ROCHAU, 24 to GAF ammo depot GRABITZ/Upper Silesia, the rest to locations in Bavaria. F-0

Trainloads contained 5% Blaukreuz, 20% Weisskreuz, 35% Gelbkreuz, and 35% Grünkreuz. May 44 a Hptm FRICKE ordered activation of the bombs stating that they would probably be needed. This was done in June. The advance of the Russians forced the evacuation of the still activated bombs. A shortage of RR cars delayed this until the end of July. 3 trainloads left daily. The entire process of transfer required 14 days.

Shells weighed 500 and 1,000 lbs, a small percentage were 100 lbs and contained Blaukreuz.

13. Chemical Warfare (Continued)

Each shell was packed horizontally in a wooden case. Cases containing Gelbkreuz were marked GB 1 and GB 2, Grünkreuz was marked GR 1 and GR 2, Weisskreuz was marked W 1 and W 2; Blaukreuz was marked Bu(Type 2 gases are more toxic). A 12 x 16 cm rectangle was painted on both ends of each case in the color designating the contents (yellow for gelbkreuz, etc). Each bomb was marked with a 7 cm wide band, 35 cm from the nose, to denote the type of the gas.

(Source: Uffz Rudolph SCHWARZ 3 Pz Gren Div captured 6 March vic Gut VOLLBERG)

14. Freeze Weapons

Freezing Grenades

PW says that his unit was given a morale talk before going into battle 27 Feb by a Hptm from the Heeresgruppe B. The Hptm said that Germany would not hesitate to resort to the most gruesome methods of warfare if expedient. He added that he did not think it would be "necessary" because of the perfection of jet propelled fighters, freezing grenades filled with ammonia, and improved Nebelwerfer.

(Source: Uffz Willi ELSNER 51 Marsch Bn captured 28 Feb)

Ten PWs (doctors) report that the appearance of a new weapon with a freezing or narcotic effect BETAUBUNGSWAFFE is expected. The new substance fired in shells or V-weapons will spread over a large area. The substance is similar to chlorine ethyl (C_2H_5Cl), its narcotic effects will last appr one day. These volatile, ether-like substances are highly explosive when mixed with air.

A statement appeared in the "Völkische Beobachter" appr 7 months ago to the effect that German planes were able to spray a highly explosive matter into a formation of enemy bombers, capable of destroying them by its explosion.

(Source: 10 PW medics)

PW heard of a new weapon which causes devastation by freezing everything within a certain radius. The cold is so intense that equipment and personnel are destroyed or immobilized. PW thinks the rumor referred to liquid spread by Arty shells and aerial bombs.

(Source: Obst v GAGG 957 Inf Regt 363 Inf Div)

Freezing wounds

Three casualties from a long range Arty tp (Fernkampf Batterie) were brought into a dispensary at BURGSTEINFORT (nr RHEINE). They were suffering from third degree freezing wounds which could not have been the result of normal winter temperature. One man's lower left leg was missing. He reported riding on a truck loaded with cans marked "A-STOFF", "B-STOFF", and "T-STOFF", when two of the cans toppled over, their contents mixed and caused the injury. The other two men refused to give the doctor any information.

15. Pressluft

Special Arty Trng

PW (Belgian) took a special Arty course in HAMM/Westphalia, 2 Oct – 2 Nov 44. The course covered the Pressluft Granate, and included 4 hrs in observation of effects at the Arty proving grounds of a trng camp at HEESEN (NE of HAMM). The course classed as secret, and including routine gas instruction, was given to 30 NCOs every 4 wks. Candidates, who were from Ersatz units, had to take an oath not to talk about the course.

Trng camp HEESEN is in a forest NW of HAMM. The impact area of Arty shells extends 10 km S toward a stream N of the LIPPE E of a Reichsautobahn to MINDEN.

Projectile

The projectile is 38 cm long, and weighs 43 kgs. The bottom is painted red, 2 copper bands are around lower portion of the shell. An aluminum percussion fuze is in the nose and just behind it is the powder train connecting with the charge. The main charge is a yellow powder (PW does not recall name) which is detonated by the percussion fuze. A time device prevents premature setting off by heat or pressure of exploding powder. The shell is fired only by 15 cm hows (SFH 18) using a heavy propelling charge (No 7). Each round is packed in excelsior in wooden boxes with red stripes diagonally across opposite corners of the cover.

Effects

PW saw 3 rounds fired. Everything within a radius of $3\frac{1}{2}$ km was laid flat by the blast of the explosion. There is no shrapnel. One round was fired within 10 m of a concrete bunker extending 1,50 m below the surface, with walls 80 cm thick. The top of the bunker was blown off. Another round was fired into a flock of sheep. They were blown into the air "like leaves". Their lungs burst and their abdomens were torn open.

The crater created by the explosion is only 50 cm deep, 1,50 – 2 m wide. PW was told that the pressure of expanding gases prevented displacement of large quantities of soil.

Firing

Crew jumped into ditches immediately after firing at a target 11 km distant. Observers take cover when shell is overhead, and through slits watch the result of impact 10 km away.

15. Pressluft (Continued)

Employment

PW saw the shells only at HEESEN trng grounds. Pressluft Granaten were thought to be especially effective against tk concentrations. Instructing Officer stated that they would be used only as a last resort for fear of Allied gas retaliation.

The supply at that time (Nov 44) was too small for effective use.

(Source: Uffz Rene MERTENS (Belgian) 1 Coy 1501 Heeres West Arty Abt captured 5 March BAERL)

Shipments of Pressluft Granaten

PW reports that he saw ammo being evacuated from an ammo dump nr KÖLN in the STADTWALD-KÖLN Forest. PW was prevented from entering the dump, and was told that Pressluft ammo was stored here. The ammo was packed in gray painted boxes appr 45-50 x 35-40 cm. PW thinks the boxes had no markings (?).

(Source: Gren Felix ZYTINSKI (Pole) 2 Tp 3 Arty Regt captured 5 March)

July 44 PW helped load 16 freight cars with 45 Pressluft Granaten each. Shells were appr 17 cm diameter and shaped like an hour-glass. Loading took place in BERLIN W of the S edge of the small KIENHORST (GSGS 4480/BERLIN/I/A 1b). Shells were shipped to XANTEN for use on the W front.

(Source: O/Gefr Johannes CARSTENS 8 Coy 1225 Inf Regt captured 2 Mar vic BROCKHUYSEN)

16. Microbe Bombs

PW saw appr one hundred 250 kg bombs stored in a hall at Flughorst Ost, MAGDEBURG. PW was told that these were microbe bombs.

As described to PW, the bomb has two detonating chambers (one in front and one in back) with 2 side fuses. In the center of the shell is an empty lead lined chamber with threaded opening on the side into which a tube is screwed. The opening has 8 threads and when the tube is screwed into the last thread it is opened and the microbes which have been stored in the tube escape into the chamber. The opening is smeared with a gelatinous substance to prevent the escape of germs.

PW thinks the germs are of cholera type.

17. Uranium Explosive

O/Lt GOTT, a chemist, OC coy in PW's bn (959 Gren Regt) had been granted indefinite leave to resume his former position as director of a chemical laboratory in S Germany. This laboratory was experimenting with uranium. It produced 1/10 milligram of an explosive which, when accidentally set off, destroyed the plant and killed the scientists engaged in the experiments. O/Lt GOTT maintained that if subsequent experiments and production have proceeded without accident, enough of the explosive should now (Feb 45) be available to "destroy England in one blow".

(Source: Lt Helmut SCHWOTZER 959 Gren Regt captured 25 Feb vic WELLDORF)

18. V-Weapon against USA

An acquaintance told PW (28 Jan) that the laboratory in SWINEMUNDE where he worked, experimented with a new rocket missile, resembling V-2, 30 m long 4-5 m in diameter. Experiments conducted with 1/25 of the explosive charge produced devastating results. It was intended to use the projectiles in nuisance bombings of the USA.

19. Atom Smasher

PW heard from friends that atom-smashing experiments (conducted somewhere NW of BERLIN) were successful and would result in the perfecting of an atom-disintegrating weapon by May 45.

20. On HITLER's Orders
(Supplementing PW INTELLIGENCE BULLETIN 1/41 item 8)

PW, who worked in the RR yards at AACHEN-ROTHE ERDE 1933 - 1944, stated that after the fall of PARIS many freight trains passing through the yards had 2 open freight cars (O type) covered with canvas and each guarded by 1 or 2 SS men. The RR workers were curious about the contents of the carefully guarded cars and took advantage of the momentary absence of the guards to look under the canvas.

PW stated the cars contained wooden boxes, appr 2.50 square, closed with rivets, and marked "To be opened on orders of the Führer only". The boxes were extremely heavy and could be moved with the aid of hoists only.

The RR men were puzzled about the contents, but Belgian workers claimed to know that a chemical shell, packed in these boxes. had a stunning, not fatal effect and was to be used for overrunning enemy forces. The workers thought the large supplies of the secret weapon had been scheduled for use in the invasion of England.

Another PW reports having seen boxes, appr 1 m long, 25 - 30 cm high, in bunkers vic WEPETAL KASERNE. The boxes were painted blue-grey and marked in white letters "To be opened on orders of the Führer only".

PW did not know what they contained but recalled having seen identical boxes before LENINGRAD.

MFIU No 2, 14 March 1945 PW INTELLIGENCE BULLETIN No 2/45

CHEMICAL WARFARE

15. New Secret Gas

Preamble. PW, an intelligent and sincere youth, was stationed in NORWAY as Ordnance Sgt with Luftgau V until Aug 44, when he was transferred to the paratroops. The transfer was principally in consequence of disparaging remarks PW had made about the Fuehrer in connection with the events of 20 July 44. Only the intervention of his OC, also an anti-Nazi, saved PW from court-martial and a possible concentration camp sentence. PW hates the Nazis bitterly and is eager to do whatever he can to help shorten the war. He believes that the use by the Germans of the weapon described below would "bring the eternal condemnation of humanity down upon us."

Because of large elements of the improbable and the fantastic in PW's story, and because of his abnormally pro-Allied attitude, every effort has been made to discredit him and prove him a plant. These efforts have not been successful. PW appears to be telling what he thinks is the truth.

Fliegerwaffentechnische Schule. At the end of Feb 44, PW and 6 other EM of Luftgau 5 were sent to I Fliegerwaffentechnische Schule, HALLE for a special course, whose nature they did not know until their arrival at the school. The school consisted of eight student coys, with 120-180 men each; one coy (8 Coy) of instructors; and three regular coys (composed of work details), with appr 60 men each.

PW's group was assigned to 4 Coy, which had appr 100 men. All the members of 4 Coy took "special courses," while the other student coys received ordnance training. 35-40 men in 4 Coy were selected for a 3-months' course entitled WWK (Waffenwartlehrgang KRIEG) 27. The remainder attended courses of equal length, the subject of which PW believes was fuzes for V and other secret weapons.

Other Schools. As of Aug 44, II Fliegerwaffentechnische Schule was at MERSEBERG, and III Schule at DRESDEN. PW does not know if similar courses were given at these schools.

Training. The course (WWK 27) at I Fliegerwaffentechnische Schule lasted from 8 March to 30 May 44, and was the first one of its type to be given. The first 2 weeks were devoted to a refresher course in ordnance subjects, which was followed by a stiff examination. The examination eliminated all but 28 members of the class. This group was divided into 2 sections of 14 members each in order to give the most intensive training possible.

Only men who had previous experience in ordnance subjects and who had previously attended a GAF course in bombs (Fliegertechnische Lehrgang fuer Abwurfwaffen) were eligible for WWK 27.

Prior to the start of the course, students were sworn in by Genlt SCHWUPP, CG of the school, who asserted that the weapon which was about to be studied would "win the war for GERMANY." Trainees were required to sign a four-fold pledge:

a. Not to mention or discuss with outsiders what they were about to see and hear.

b. Not to correspond with non-German women.

c. To make no mechanical drawings whatsoever.

15. New Secret Gas (Continued)

d. To discuss with no one any matters pertaining to the school, the course, or the weapon, particularly not to talk about such matters with foreign engineers with whom they might come in contact in the occupied countries in which many of them were stationed.

Additional security lectures were given at intervals, each lecture being based on one of the topics listed above. These lectures were also given by the CG.

Schedule.

2 weeks at HALLE	theoretical study
2 weeks at RECHLIN	practical exercises
Second period at HALLE	theoretical study
10 days at RECHLIN	practical exercises
Third period at HALLE	theoretical study
2 weeks at RECHLIN	practical exercises

Purpose of Course. At RECHLIN the trainees studied a new war gas, including its use as an airborne weapon in a spraying device attached to a/c.

The Gas. PW describes the new gas in its liquid state as being comparable in viscosity to egg white. The liquid has a specific gravity of appr 1.3. It has a grayish-brown color, opalescent when seen from an angle, gives off spectral reflections. It has the appearance of Diesel oil, according to PW, who cannot describe its odor because the students always wore complete protective equipment when handling it. It was even referred to as "Kleister" (glue). It has no code name or identifying number.

Students observed experiments conducted at RECHLIN. In one of these, a drop was placed on a rabbit's back, about a third of the distance from its head to its tail. In 2-3 minutes the animal was dead. Its hair bristled slightly. The skin (gray) became darker. The rabbit seemed to die in a convulsion. "Death without blood" it was called by the students.

Effect on Metals. Bronze, gold, silver, zinc, lead, copper, and tin plates, 8-10 mm thick, 8 cm long, and 6 cm wide, were sprayed. Thus sprayed, the metals gave off a white vapor. After a few minutes the plates were worked over with a glass hammer. Impressions were left wherever the hammer struck. The lead plate showed the greatest resistance. PW calls the result of the experiment "Zersetzung des Kerns" (decomposition of the substance).

The barrel of a 2 cm Flak was sprayed, resulting in 60% decomposition. The metal apparently lost its intra-molecular cohesion, and the weapon was rendered useless.

One drop of the substance was dropped on earth, whereupon the substance turned grayish-green and vaporized. After appr 7 minutes it turned grayish-white in color.

In the course of the experiments a drop of the substance fell on a trainee's arm at a point just above the wrist, necessitating the immediate amputation of the arm at a point just above the elbow.

PW INTELLIGENCE BULLETIN No 2/45

15. New Secret Gas (Continued)

Storage. The liquid is stored in a heavy glass demijohn (see ANNEX III) with a capacity of 50 liters. (PW heard that other sizes are being developed.) The glass has a thickness of appr 5 cm, with an overall length of appr 1 meter. The demijohn is 80-90 cm in diameter, and is filled to a height of 60-65 cm, leaving 15-20 cm air gap. The demijohn is sealed with a fitted airtight glass stopper, and is then strapped with metal bands.

Spraying Unit. PW knows of 3 sires of tanks equipped with spraying devices and ready for attachment to airplanes:

S (Spruchbehaelter) 125, with capacity of appr 98 liters. (See ANNEX IV

S 200, with capacity of appr 150-160 liters.

S 300, with capacity of 220-240 liters.

Larger sizes were anticipated at the time PW was at the school.

The S 125 is cigar-shaped, 1.60 m long and 72 cm at its greatest diameter. It is made of glass (said to be bullet-proof) of an estimated thickness of 4-5 cm. Air space is left when the tank is filled with the liquid. A metal band 8-10 cm wide and lined with felt is strapped around the tank. A metal bottle, 40 cm long, containing a substance comparable to the chemical used in fire extinguishers and with a pressure of 2 atmospheres (never any greater) is also strapped to the tank. It is apparently used to force the liquid out of the tank. In actual use, when an a/c is warmed up and ready to take off, and only then, a ground crew man opens a valve between the pressure bottle and the tank containing the liquid "gas." Thus transmitting the pressure into the tank.

A solenoid magnet valve is located at the smaller end of the tank connecting the tank with the nozzle. The pilot releases the liquid through the valve by means of a push-button control. The valve, which is made of metal, has a very low resistance to the liquid, and it is therefore possible to release only three sprayings, which must be accomplished within a 6-minute period. After the third spraying, the valve must be replaced. The liquid passes through the valve and down into the nozzle. The nozzle is a truncated cylinder with perforations so placed in the rear two thirds of the wall and in the bottom end as to give the spray a rearward and downward direction and thus to prevent the expelled liquid from coming into contact with the a/c.

Filling of Spraying Unit. Extreme caution is necessary in handling the substance. No fires or open lights are permitted within a radius of 100 meters. Personnel is equipped with a super-heavy rubber suit, weighing appr 25-30 kg, including diver's helmet. The suit consists of an outer layer of appr 5 mm of rubber, 3 mm of a gelatinous substance, and a double lining of linen. The rubber gloves, which extend to above the elbow and have no gelatinous lining, can be used only once. The gloves are strapped above the elbow to insure a tight fit. Personnel also wear super-heavy rubber boots, which extend to above the knee. Oxygen is provided by a respirator (Heeresatmergeraet). PW does not think ordinary army protective gas equipment would afford adequate protection against this gas.

A flexible glass hose is used for filling spraying unit S 125. The hose, appr 3 m long, is reinforced by wire mesh with a rubber-bakelite coating, and is inserted in a 50-liter bottle. By means of a pump and straining unit housed in a bell jar the liquid is pumped from the demijohn into the tank of the spraying unit.

PW INTELLIGENCE BULLETIN No 2/45

15. New Secret Gas (Continued)

Packing of Demijohns. One 50-liter demijohn is packed in a wooden case, (see ANNEX III) appr 1.50 m long, 1.70 m wide, and 1.30 m high. The case has 2 partitions, in one of which the bottle, packed in excelsior, stands upright. The other section holds a rubber suit, a pump and straining unit, several hoses, and spare valves, all packed in excelsior. The JUNKERS trade mark (a winged figure inside an isosceles triangle) and a number are printed on the outside of the box. PW believes that the trademark is used only for deception. He does not think there is any connection between JUNKERS and the product.

PW passed through TROISDORF on his way to the front on 5 Dec 44. In the RR station there he saw a train consisting of about 40 cars loaded with boxes which he recognized as being either the same as those described above or very similar to them. He did not find out what was in the boxes. The train was guarded by SS troops.

Attachment to A/c. According to PW the spraying unit is attached to the wing of a/c in the same manner as bombs. The number of units depends on the type of a/c. The pilot can release the liquid in all the tanks simultaneously. A demonstration of the unit in operation, using water instead of the liquid gas, was given at RECHLIN while PW was there. In the event of an emergency landing, the load is jettisoned (over water if possible) by releasing the units complete.

The loads which can be carried by various planes is as follows;

	S 125 Unit	S 200 or 300	+	S 125 Unit
JU-88	6	2	+	4
HE-177	9	4	+	4
ME-210	4		?	
ME-410	4		?	
ME-109	3	1	+	2
FW-190	3	1	+	2

All the units are fastened to a/c by standard ETC-Traeger (Elektrische Traeger fuer zylindrische Lasten). They are held in position by clamps and the glass is protected against breakage by rubber pads.

The most effective use is made of the unit when the airplane is at an altitude of 80-100 m.

Other Uses. The gas can also be used as a ground weapon, on the principle of the flamethrower. The ground unit has 3 glass bottles, each with a capacity of appr 6 liters, as well as a pressure bottle, carried on the operator's back. Liquid is released through a hose made of a glass material. PW's only contact with the ground weapon was a demonstration given in class. It was explained that the primary use of the weapnn was to deny areas to the enemy by chemical contamination.

PW INTELLIGENCE BULLETIN No 2/45

15. New Secret Gas (Continued)

Experiments had also been conducted at RECHLIN using this gas with jet-propelled planes and V-weapons, but PW did not witness these experiments.

Storage in NORWAY. On completion of his course, PW returned to his station in NORWAY. (He does not know if other classes followed at HALLE.) On direct orders of Luftflotte 5, PW was put in charge of examining guards and the material they were guarding at secret dumps (Geheimlager) at various Luftparke in NORWAY.

Before his departure end of Feb 44 for the school (previously recounted), large quantities of the gas had arrived at Luftgau 5 by plane. PW would spot-check the stores of the gas. A special certificate issued by Luftflotte 5 permitted him to enter the secret stores. PW claims that not even high-ranking Luftflotte officers were aware of the nature of the stores. PW checked for leakage and dry storage. In only one instance did he find some cases stored in a damp spot. On orders of Luftflotte 5, this was corrected immediately.

When PW left NORWAY in Aug 44, the following was stored at the Luftparke indicated:

OSLO

900-1000 cases, each containing one 50-liter demijohn
300-400, each containing one S 125 spraying unit
15-20 cases of protective clothing

BERGEN, STAVANGER, and TRONDHEIM

At each Luftpark:

150 cases, each containing one 50-liter demijohn
40 cases, each with one S 125 spraying unit
Several cases of protective clothing
There were also "Ueberdruckgranaten" for Do-Geraet stored at STAVANGER-FORUS.

KEVIK, nr KRISTIANSSAND

240 cases, each containing one 50-liter demijohn
150-180 cases, each with one S 125 spraying unit
Several cases of protective clothing
There were a few S 200s mixed in with the S-125's listed abo

The secret stores are very heavily guarded by special 24-man guard details. A relief consists of 6 men, equipped with MGs, automatic rifles, and hand grenades. Minefields have been laid in front of the storage buildings, and the installations are heavily protected by Flak (8.8 cm and 10.5 cm).

According to PW, the Germans consider NORWAY a safe storage place for the gas, since that country has not been subjected to invasion or air attacks.

PW knows of no storage places for this gas outside of NORWAY. However, hi classmates returned to their proper stations (unidentified Fliegerhorste). PW was relieved in OSLO by O/Feuerwerker PETHAN (Luftflotte V, OSLO).

Similar Use of Other Gases. According to PW, experiments have also been co ducted at RECHLIN with spraying units which are made of metal and filled with different substances: Gelbkreuz (yellow-cross gas), Blaukreuz (blue-cross gas), and a phosphorous solution. When the phosphorous solution is released, it begi to glow appr 400 m above the ground. On reaching the ground it attains maximum burning effect.

PW INTELLIGENCE BULLETIN No 2/45

16. Poison Gas Manufacture

Preamble. PW, a 21-year-old Austrian, was sentenced to a concentration camp in 1940 for having listened to foreign radio stations. Until 1942 he was in Strafgefangenenlager (Lager 1), DIEBURG. He served the remainder of his sentence at Strafgefangenenlager (Lager 2), OBERRODEN. In Sept 44 he was sent to the Army direct from the camp.

MERCK & Co. DARMSTADT

From 1941 until the beginning of 1944, PW was a member of a 60-man detail which was sent to MERCK & Co, DARMSTADT, for 2-week periods about every 3 months. The detail worked on the repair of RR tracks. During each of his stays at DARMSTADT, PW saw 8-10 standard RR freight cars being loaded with cylinders of poison gas. The top and upper half of each cylinder was painted in one of 5 colors, red, green, white, blue, or yellow.

PW did not have access to the plant which produced the gas. He saw small groups of men changing shifts every 2 hours. Although they wore gas masks while at work, the men coughed habitually and spat blood. Their faces were haggard and yellow. They received an extra milk ration of appr 1 liter per day. PW estimates that appr 30 men were employed in the gas-producing plant.

The mask, which looked like a regular service gas mask, was made of canvas with protective leather trimming. The face-piece was connected by a rubber hose to an oxygen bottle, made of copper, appr 25 cm long and 15 cm in diameter. A valve was fitted to the top of the bottle.

LUVA-HAUPT-MUNA, DIEBURG

Up to April 44, PW's detail was also frequently taken to the Luftwaffe-munitionshauptlager, (GAF central ammunition depot), DIEBURG, called LUVA-HAUPT-MUNA. A spur which branches off the DIEBURG-EPPERTSHAUSEN-OBERRODEN RR line at EPPERTSHAUSEN leads to a plant within the depot where shells and other ammunition were filled with explosives.

Location. The depot, including the plant, is bounded by the coordinates GSGS 4414/6018/766481 - 776482 - 773494 - 764493.

Appr 3 times a week two or three of the same RR cars PW had seen at the MERCK factory arrived at the plant. These cars, which brought cylinders of poison gas from the MERCK factory, were required to be unloaded immediately. The poison gas was immediately used to fill shells. The empty cylinders were then loaded back onto the cars, which returned the same afternoon to the MERCK factory.

PW describes the shells as appr 7-8 mm thick, 50-60 cm long, and appr 25 cm in diameter. The shells were painted yellow and marked on one side with a cross 4 x 4 cm in red, green, white, or blue. The gas-filled shells were not stored at the DIEBURG depot. PW does not know where they were sent.

A.4.2 Allied/Axis Threats of Mutual Assured Destruction

[Unlike the view in conventional history books, the following documents demonstrate that both Axis and Allied forces very nearly used chemical weapons and other weapons of mass destruction (WMDs) in World War II, and that the threats by both sides to use chemical and other WMDs played an enormously important role in how and why the war was waged as it actually was.

Germany stockpiled and very seriously considered using its chemical weapons (both the newer ones like nerve agents and the older ones like mustard agent) against Allied targets, especially to halt Russian advances on the Eastern Front. It also appears to have had fuel-air explosives (p. 557), biological weapons (Section A.3), and nuclear weapons (Appendix D; see especially Section D.13).

The United States and United Kingdom stockpiled and very seriously considered using their own copies of the chemical weapons that Germany had invented in the previous war (mustard and phosgene) with the explicit goal of killing millions of civilians in German cities. In addition, the U.K. had a stockpile of anthrax-infected cattle feed that could be dropped on German farms, and the U.S. had fission products from its recently built breeder reactors that could be dropped on German cities as a radiological weapon.

These documents show that the Allies considered using their chemical and other WMDs not only in response to any use of German chemical weapons, but also in response to the use of other novel German weapons, such as V-2 rockets carrying conventional explosives. Thus the Allies almost certainly would have launched a massive attack on German civilian populations if Germany had used any form of WMDs, including nuclear or biological weapons. This was confirmed by the German general Heinrich Kittel in a secret recording in January 1945 (pp. 3786–3791). See also pp. 2645–2646.

These documents are also a clear example of how Allied countries covered up important wartime events and decisions, kept information about them classified for decades, and are known to still be keeping relevant archival documents classified and unavailable to the public and to historians.

Thus behind the conventional warfare history of World War II that the public knows, there was a far less visible yet likely even more important game of deterrence and brinksmanship between the Allied and Axis forces involving weapons of mass destruction. On the Allied side were massive numbers of crude but effective weapons. On the Axis side were massive numbers of far more sophisticated chemical weapons, as well as currently unclear but apparently quite real numbers of nuclear weapons, biological weapons, and other novel weapons such as fuel-air explosives. Each side appears to have been well aware of the threats posed by the other side, and that shaped their strategic choices in how the war played out.

[For additional information and archival references, see Gellermann 1986.]

The details of these Axis and Allied programs should be clarified, and this aspect of the war should be given the treatment it deserves in books on the history of World War II.]

Henry Picker. 2009. *Hitlers Tischgespräche im Führerhauptquartier.* 2nd ed. Berlin: Propyläen-Taschenbuch bei Ullstein. p. 668.

Aus diesem Grunde recherchierte Hitler Okt./Nov. 1944 noch einmal bei der britischen Regierung bezüglich eines Minimalagreements, das den Briten die Erhaltung ihres Empire und Deutschland die Stabilisierung der Ostfront auf der Linie Memel—Kaschau [Klaipeda—Kosice] unter enger Anlehnung an die Flüsse Narew und Weichsel tolerieren sollte. Auf Leys Vorschlag wollte Hitler auf dieser etwa 750 km langen Front zwischen die deutschen und die russischen Truppen einen Giftgas-Vorhang legen. Zur Vorbereitung hatte er bereits für die deutsche Wehrmacht Millionen von Gasmasken produzieren und Gaskriegvorbereitungen befehlen lassen. Für die Giftgaswand wollte Hitler die Kampfstoffe Lost und Tabun verwenden. Seit 1939 hatte er monatlich im Schnitt 3100 t Lost und 1000 t Tabun herstellen lassen. Lost machte mit ihm verseuchte Gebiete längerfristig unbetretbar, da es Nervenstörungen, Sehbehinderungen, Atembeschwerden und Hautverätzungen herbeiführte. Tabun war tödlich selbst bei kleinsten Dosen. Die Gasmasken der Roten Armee waren für beide Gifte in der deutschen Zusammensetzung kein ausreichender Schutz. Churchill liess Hitler Vorschläge jedoch zurückweisen. Ja, er drohte, Grossbritannien werde als Gegenmassnahme sofort seine gesamten Giftgasvorräte von 32000 t Gelbkreuz und Phosgengas über Deutschlands Großstätde “abregnen” lassen und damit 2500 qkm deutschen Großstadtraums total lebensvernichtend zerstören. Hitler entnahm daraus, dass Churchill selbst ein Deutschland in den Vorkriegsgrenzen nicht überleben lassen wollte.

For this reason, in Oct./Nov. 1944, Hitler again made inquiries of the British government concerning a minimum agreement that would tolerate the British maintaining their Empire and Germany stabilizing the Eastern Front on the Memel-Kaschau [Klaipeda—Kosice] line, closely following the Narew and Vistula Rivers. At Ley’s suggestion, Hitler wanted to place a poison gas curtain between the German and Russian troops on this front, which was about 750 km long. In preparation, he had already had millions of gas masks produced for the German Wehrmacht and gas war preparations ordered. For the poison gas wall Hitler wanted to use the warfare agents mustard and tabun. Since 1939, he had an average of 3,100 tons of mustard and 1,000 tons of tabun produced every month. Mustard made areas contaminated with it inaccessible for a longer period of time, since it caused nerve disorders, impaired vision, respiratory problems and skin burns. Tabun was lethal even at the smallest doses. Red Army gas masks were inadequate protection for either poison in the German composition. Churchill, however, made Hitler reject the suggestions. Yes, he threatened that Britain would immediately “rain” its entire poison gas stockpile of 32,000 tons of mustard and phosgene gas over Germany’s major cities as a countermeasure, totally destroying 2,500 sq. km. of German urban space. Hitler took from this that Churchill did not want to let Germany survive even within its prewar borders.

Rochus Misch. 2014. *Hitler’s Last Witness: The Memoirs of Hitler’s Bodyguard.* Barnsley, U.K.: Frontline Books. p. 60.

I remember seeing a report about the development of the atom bomb. It stated that the American research was at least nine months behind the German. [...] The Western Allies had threatened that, if Germany used the atom bomb, they would assemble 15,000 aircraft in North Africa and use them to drench all of Germany with poison gas.

[See also p. 4667 and the other sources quoted throughout Section D.13.]

Winston Churchill. 10 May 1942. Broadcast Report on the War. British Library of Information. [https://www.ibiblio.org/pha/policy/1942/1942-05-10a.html]

We send our salutations to the Russian armies and we hope that the thousands of tanks and aeroplanes which have been carried to their aid from Britain and America will be a useful contribution to their own magnificently developed and reorganized munitions resources.

There is, however, one serious matter which I must mention to you. The Soviet Government have expressed to us the view that the Germans in the desperation of their assault may make use of poison gas against the armies and people of Russia. We are, ourselves, firmly resolved not to use this odious weapon unless it is used first by the Germans. Knowing our Hun, however, we have not neglected to make preparations on a formidable scale.

I wish now to make it plain that we shall treat the unprovoked use of poison gas against our Russian ally exactly as if it were used against ourselves and if we are satisfied that this new outrage has been committed by Hitler we will use our great and growing air superiority in the West to carry gas warfare on the largest possible scale far and wide against military objectives in Germany.

It is thus for Hitler to choose whether he wishes to add this additional horror to aerial warfare.

We have for some time past been bringing our defensive and precautionary arrangements up to date and I now give public warning so that there may be no carelessness or neglect. Of one thing I am sure: that the British people who have entered into the full comradeship of war with our Russian ally will not shrink from any sacrifice or trial which that comradeship may require.

Meanwhile, our deliveries of tanks, aircraft and munitions to Russia from Britain and from the United States continue upon the full scale. We have the duty of escorting the northern convoys to their destination.

[In addition to being broadcast on radio stations, Churchill's speech was printed and reported in many newspapers around the world. See for example:

Text of Churchill Speech. *Evening Star* (Washington, DC) 11 May 1942, p. A-13.
https://chroniclingamerica.loc.gov/lccn/sn83045462/1942-05-11/ed-1/seq-15/

Churchill Optimistic In War Report, Warns Nazis on Poison Gas. *Evening Star* (Washington, DC) 11 May 1942, p. A-2. https://chroniclingamerica.loc.gov/lccn/sn83045462/1942-05-11/ed-1/seq-4/

It was surely noticed by German officials, as Churchill intended.]

Urgency of Gas Warning. *The Courier-Mail* (Brisbane, Queensland, Australia) 1943-04-24 p. 2.

LONDON, April 23 (Special—A.A.P.).—Mr. Churchill's warning that the Germans might soon use gas against the Russians is regarded as grave.

Without the customary notice to the Press, and at the unusual hour of 1 a.m., the statement was issued from No. 10 Downing Street as follows:—

> "Reports have been received from several sources that Hitler is preparing to use poison gas on the Russian front.
>
> "Accordingly the Government will take early occasion to renew the Prime Minister's warning of last year that any use of poison gas against our Russian allies by the Nazis or their satellites will immediately be followed by the fullest possible use of this process of war upon German munition centres, sea ports, and other military objectives in Germany.
>
> "British resources and the scale of delivery have greatly increased since last year.
>
> "Necessary precautionary measures against reprisals already have been enjoined by competent authorities in the United Kingdom."

Fresh Advice

Issue of the statement so suddenly and at 1 a.m. is taken to mean that Mr. Churchill received further information on Germany's gas intentions of such a nature that he did not hesitate, despite the late hour, to issue it to the newspapers immediately.

Soon after issue of the statement, the B.B.C. broadcast it fully to the German people. The announcer read the statement without any preliminaries, and repeated it after the news bulletin.

Mr. Churchill's earlier warning was given in a broadcast on May 10, 1942. After 24 hours' silence the German radio then said that Germany would abide by the pledge given at the outbreak, namely, that Germany would not use poison gas unless her enemies used it first.

Hitler in Rage?

An official of the Soviet Embassy told the Daily Mail: "We passed on to the British Foreign Office information that supplies of poison gas recently reached the German armies on the Russian Front."

Reports have long been current that Germany's setbacks, particularly the tremendous effect of the R.A.F.'s bombing, have sent Hitler into a rage.

It is felt in London that Hitler's relative inaction in Europe is not because his resources are so strained, and may prove very deceptive.

The story was also printed in many other newspapers around the world.]

Leaflets such as this one (Fig. A.256) were dropped on Germany by Allied planes in 1943 [Gellermann 1986, p. 245].

GAS

Am 21. April 1943 gab die britische Regierung folgende Erklärung ab: Nach Berichten aus verschiedenen Quellen trifft Hitler Vorbereitungen zum Gaskrieg an der Ostfront. Die Britische Regierung wiederholt daher die bereits im Vorjahr von Premierminister Churchill ausgesprochene Warnung: Jede Anwendung von Giftgas gegen das mit Grossbritannien verbündete Russland wird zur unmittelbaren Folge haben, dass dieses Kriegsmittel auch von Grossbritannien in grösstmöglichem Ausmass gegen die Zentren der deutschen Rüstungsindustrie, sowie gegen Häfen und andere militärische Ziele in ganz Deutschland angewandt wird. Grossbritanniens Vorbereitungen für einen etwaigen Gaskrieg haben seit dem vergangenen Jahr grosse Fortschritte gemacht. Die erforderlichen Vorkehrungen gegen deutsche Vergeltungsmassnahmen sind von den zuständigen Behörden bereits im ganzen Land angeordnet worden.

GAS

On 21 April 1943, the British government issued the following statement: According to reports from various sources, Hitler is making preparations for gas warfare on the Eastern Front. The British Government therefore repeats the warning already issued the previous year by Prime Minister Churchill: Any use of poison gas against Russia, which is an ally of Great Britain, will have the immediate consequence that this means of war will also be used by Great Britain to the greatest possible extent against the centers of the German armaments industry, as well as against ports and other military targets throughout Germany. Britain’s preparations for a possible gas war have made great strides since last year. The necessary precautions against German retaliatory measures have already been ordered by the relevant authorities throughout the country.

[Note that this warning translated into German is essentially the same as the statement that the U.K. government issued to international media (p. 2635). Rushed distribution of this warning in both forms suggests that Allied intelligence was convinced that Germany was highly likely to launch chemical attacks on the Eastern Front within a matter of days or weeks, and that the United Kingdom wanted to do everything possible to deter that.]

Franklin D. Roosevelt. 8 June 1943. Statement Warning the Axis Against Using Poison Gas. [Online by Gerhard Peters and John T. Woolley, The American Presidency Project. https://www.presidency.ucsb.edu/documents/statement-warning-the-axis-against-using-poison-gas]

From time to time since the present war began there have been reports that one or more of the Axis powers were seriously contemplating use of poisonous or noxious gases or other inhumane devices of warfare.

I have been loath to believe that any Nation, even our present enemies, could or would be willing to loose upon mankind such terrible and inhumane weapons. However, evidence that the Axis powers are making significant preparations indicative of such an intention is being reported with increasing frequency from a variety of sources.

Use of such weapons has been outlawed by the general opinion of civilized mankind. This country has not used them, and I hope that we never will be compelled to use them. I state categorically that we shall under no circumstances resort to the use of such weapons unless they are first used by our enemies.

As President of the United States and as Commander in Chief of the American armed forces, I want to make clear beyond all doubt to any of our enemies contemplating a resort to such desperate and barbarous methods that acts of this nature committed against any one of the United Nations will be regarded as having been committed against the United States itself and will be treated accordingly. We promise to any perpetrators of such crimes full and swift retaliation in kind and I feel obliged now to warn the Axis armies and the Axis peoples, in Europe and in Asia, that the terrible consequences of any use of these inhumane methods on their part will be brought down swiftly and surely upon their own heads. Any use of gas by any Axis power, therefore, will immediately be followed by the fullest possible retaliation upon munition centers, seaports, and other military objectives throughout the whole extent of the territory of such Axis country.

[Roosevelt's statement was published around the world as a clear message to the Axis powers that the United States was prepared to use chemical weapons if the Axis used anything other than conventional weapons.

Dwight D. Eisenhower. 1948. *Crusade in Europe.* New York: Doubleday. Ch. 12.

On December 2, 1943, a most regrettable and disturbing incident took place at the port of Bari. We were using that port to assist in the support of the Eighth Army and the large air forces we were rapidly building up in Italy. It was constantly crowded with ships and the port itself was located uncomfortably close to some of the enemy air bases just across the narrow Adriatic.

One night the port was subjected to a raid and we suffered the greatest single loss from air action inflicted upon us during the entire period of Allied campaigning in the Mediterranean and in Europe. We lost sixteen vessels, some of them loaded with extremely valuable cargo. The greatest damage arose from the fact that a fuel ship was struck and the escaping oil carried fiery catastrophe to many of the neighboring vessels. One circumstance connected with the affair could have had the most unfortunate repercussions. One of the ships was loaded with a quantity of mustard gas, which we were always forced to carry with us because of uncertainty of German intentions in the use of this weapon. Fortunately the wind was offshore and the escaping gas caused no casualties. Had the wind been in the opposite direction, however, great disaster could well have resulted. It would have been indeed difficult to explain, even though we manufactured and carried this material only for reprisal purposes in case of surprise action on the part of the enemy.

[Eisenhower's postwar statement that there were no casualties from the U.S. mustard agent at Bari was a knowing and blatant falsehood, as shown on p. 2643. However, this case serves as an excellent example of an important wartime incident that was deliberately denied and suppressed by the United States and United Kingdom for decades after the war. What other factual wartime events and programs were also denied even decades after the war?]

Jennet Conant. 2020. *The Great Secret: The Classified World War II Disaster that Launched the War on Cancer.* New York: W.W. Norton. pp. 293–295, 318–319.

Lt. Col. Alphonsus d'Abreu, the officer in charge of the surgical division of the 98th British General Hospital in Bari, did not approve of the deletions or the whitewashing of history. "I hope you will forgive me when I deny the accuracy of your statement that the escaping gas caused no casualties," he wrote Eisenhower, his former commanding officer in Italy, on January 26, 1949. "I was stationed there at the time and was responsible for the management of some 1,280 casualties of all nationalities," he continued, adding that he still had his notes, "and I am afraid the death toll was very high." Most of the casualties were caused by the mixture of mustard gas and oil in the harbor and "were in fact very severely contaminated and many of them died later of the well known lung complications of this fearful chemical." [...]

Eisenhower [...] was already mulling a run for the presidency[....] "While I have not yet had an opportunity to check back through official records, I shall do so," he assured d'Abreu, "and a correction will be made in future printings." No correction was ever made.

In the fifth installment of his voluminous memoirs of World War II, *Closing the Ring*, published in 1951, Churchill continued to cling obstinately to his position that there was no mustard gas in Bari. [...]

On October 9, 1987, the *American Medical News* reported, "Thus, 44 years after Bari, and 22 years since Churchill's death, the division is delving into musty, old, never released records and into the role of Stewart Alexander, MD, then a brash young lieutenant colonel and chemical warfare expert, who made what was one of the most politically sensitive diagnoses ever made." [...]

On Friday, May 20, 1988, at a small ceremony in the Capitol, a white-haired Alexander [...] received the long-overdue military honor. [...]

In the press conference afterward, Captain Mark Yow, assistant executive officer to the surgeon general, explained that the US Army could not have honored Alexander until recently, when the British declassified the documents relating to the incident. (The British are the masters of the slow reveal: The bulk of the Bari incident files were declassified in 1971, a group of Air Ministry papers a decade later, but some were not opened until 2008. Still others will not be released until 2044.) It was noted that the British government had no plans for any official UK honor for the doctor's work at Bari.

[In addition to the at least 1,280 military casualties noted by d'Abreu, there were probably even more casualties among civilians who were in the harbor or on the shore. Those civilian casualties were never properly investigated and tallied. Of those who were not killed outright by the mustard agent, many developed cancer or other long-term health problems, as discussed in Conant's book.

If a wartime event such as this could be classified, denied, and buried for so long (with some files on the Bari incident that still will not be released until at least 2044), what other wartime secrets remained buried just as deeply, or even more deeply?]

Winston S. Churchill to General Hastings Ismay. 6 July 1944. [https://www.heraldscotland.com/news/12251410.memo-from-winston-churchill-to-general-ismay-date-july-6-1944-it-may-be-several-weeks-before-i-ask-you-to-drench-germany-with-poison-gas-and-if-we-do-it-let-us-do-it-one-hundred-per-cent/ and https://nhd.org/wp-content/files/The%20Bari%20Incident%20-%20Lesson%20Plan.pdf]

1. I WANT you to think very seriously over this question of poison gas. I would not use it unless it could be shown either that (a) it was life or death for us, or (b) that it would shorten the war by a year.

2. It is absurd to consider morality on this topic when everybody used it in the last war without a word of complaint from the moralists or the Church. On the other hand, in the last war the bombing of open cities was regarded as forbidden. Now everybody does it as a matter of course. It is simply a question of fashion changing as she does between long and short skirts for women.

3. I want a cold-blooded calculation made as to how it would pay us to use poison gas, by which I mean principally mustard. We will want to gain more ground in Normandy so as not to be cooped up in a small area. We could probably deliver 20 tons to their one and for the sake of the one they would bring their bomber aircraft into the area against our superiority, thus paying a heavy toll.

4. Why have the Germans not used it? Not certainly out of moral scruples or affection for us. They have not used it because it does not pay them. The greatest temptation ever offered to them was the beaches of Normandy. This they could have drenched with gas greatly to the hindrance of our troops. That they thought about it is certain and that they prepared against our use of gas is also certain. But the only reason they have not used it against us is that they fear the retaliation. What is to their detriment is to our advantage.

5. Although one sees how unpleasant it is to receive poison gas attacks, from which nearly everyone recovers, it is useless to protest that an equal amount of HE will not inflict greater cruelties and sufferings on troops or civilians. One really must not be bound within silly conventions of the mind whether they be those that ruled in the last war or those in reverse which rule in this.

6. If the bombardment of London really became a serious nuisance and great rockets with far-reaching and devastating effect fell on many centres of Government and labour, I should be prepared to do anything that would hit the enemy in a murderous place. I may certainly have to ask you to support me in using poison gas. We could drench the cities of the Ruhr and many other cities in Germany in such a way that most of the population would be requiring constant medical attention. I do not see why we would always have all the disadvantages of being the gentleman while they have all the advantages of being the cad. There are times when this may be so but not now.

7. I quite agree it may be several weeks or even months before I shall ask you to drench Germany with poison gas, and if we do it, let us do it 100%. In the meanwhile, I want the matter studied in cold blood by sensible people and not by that particular set of psalm-singing uniformed defeatists which one runs across now here now there. Pray address yourself to this. It is a big thing and can only be discarded for a big reason. I shall of course have to square Uncle Joe and the President; but you need not bring this into your calculations at the present time. Just try to find out what it is like on its merits.

WS
6. 7. 44.

Vom Himmel hoch: Ein geheimer Plan enthüllt, daß die Amerikaner gegen Kriegsende bereit waren, einen großen Teil der deutschen Bevölkerung mit Giftgas zu vernichten. [From high in the sky: A secret plan reveals that toward the end of the war the Americans were prepared to exterminate a large part of the German population with poison gas.] *Der Spiegel* 23 October 1988.

Erst ein Zufallsfund des württembergischen Privatforschers und Fachautors Fritz Hahn, 66, in einem Washingtoner Archiv enthüllt die Dramatik eines Planes, den die US-Kriegführung unmittelbar nach dem "Ersteinsatz von Gas durch die Achsenmächte" ("G-Day") verwirklichen wollte. Danach sollten, von Italien und England aus, Tausende Flugzeuge "in einer 15-Tage-Operation"...

– 30 deutsche Großstädte mit Senfgas und/oder dem noch giftigeren Phosgen einnebeln.

– Alle wichtigen Industrie- und Fabrikationsanlagen zerbomben und so den Zweiten Weltkrieg in Europa mit einem Schlag beenden.

Unter Punkt 4 des Plans ("Mögliche Ergebnisse des Angriffs") errechneten US-Spezialisten der Abteilung für Chemiekriegführung, wie viele Menschen "direkt beeinträchtigt", also getötet würden—"5600000". Weitere zwölf Millionen "würden dem vorgeschlagenen Angriff indirekt ausgesetzt" sein. [...]

Für alle 30 Städte, vom US-Verteidigungsministerium und von Geheimdienstlern als "Schlüsselziele" ausgesucht, gab es präzise Beschreibungen jener Viertel, die als Angriffsobjekt "empfehlenswert" seien—in Hamburg, beispielsweise, waren es drei:

I. Dieses Ziel umfaßt die Innenstadt mit einer Fläche "von einer Quadratmeile ... annähernd 200000 Personen (nächtliche Bevölkerung um 100000), das Geschäfts- und Speicherzentrum. Angrenzend im Süden der Hafen längs der Elbe, eingeschlossen sind die U-Boot-Werften."

Only a chance find by Fritz Hahn, 66, a private researcher and specialist author from Württemberg, in a Washington archive reveals the drama of a plan that the U.S. war leadership wanted to implement immediately after the "first use of gas by the Axis powers" ("G-Day"). According to this plan, from Italy and England, thousands of planes were to "in a 15-day operation":

– Fog 30 major German cities with mustard gas and/or the even more poisonous phosgene.

– Bomb all major industrial and manufacturing plants, ending World War II in Europe in one fell swoop.

Under point 4 of the plan ("Possible Results of the Attack"), U.S. specialists in the Chemical Warfare Division calculated how many people would be "directly affected," i.e., killed—"5,600,000." Another twelve million "would be indirectly exposed" to the proposed attack. [...]

For all 30 cities, selected by the U.S. Department of War and intelligence officials as "key targets," there were precise descriptions of those neighborhoods that were "recommendable" as targets for attack—in Hamburg, for example, there were three:

I. This target comprises the inner city with an area "of one square mile . . . approximately 200,000 persons (nightly population around 100,000), the business and warehouse center. Adjacent to the south the port along the Elbe, enclosed are the submarine yards."

II. Dieses Ziel umfaßt das dichtbevölkerte Wohngebiet ”östlich des Altonaer Bahnhofs, nördlich der Elbe und des Parkgürtels um die Innenstadt, südlich von Eimsbüttel, des dichtbesiedeltsten Stadtteils. In diesem anderthalb Quadratmeilen großen Zielgebiet leben 190000 Menschen.”

III. Dieses Ziel umfaßt die dichtbesiedelten “Wohngebiete im Nordosten der Stadt. In diesem anderthalb Quadratmeilen großen Zielgebiet leben 140000 Menschen.”

Fünf Städte—München, Augsburg, Nürnberg, Stuttgart und Karlsruhe—sollten vom italienischen US-Stützpunkt Foggia, rund 100 Kilometer nördlich von Bari, angeflogen werden. Alle anderen—unter ihnen Berlin, Köln, Düsseldorf, Leipzig und Dresden—von London aus.

Je nach den klimatischen Bedingungen wären das leicht flüchtige Phosgen oder der schwerere Lost abgeworfen worden. Dabei kalkulierten die Planer zur Vergiftung “einer Quadratmeile” den Einsatz von mindestens “100 Flugzeugen mit 4000 Bomben a 100 Pfund (Lost)” oder “600 Bomben a 1000 Pfund (Phosgen)” ein.

Amerikas Chemiefabriken hatten genügend Kampfstoff produziert, gegen Ende des Krieges lagerten in den Arsenalen 140000 Tonnen. Aber es standen zum damaligen Zeitpunkt nicht genügend Bomber bereit.

Bei einem Angriff im März 1944 hätte die amerikanische Luftwaffe jedoch 63 Prozent des “Zielprogramms” erledigen können, im Juni schon 76 Prozent. Möglich scheint, daß die Briten im Bedarfsfall mitgeflogen wären, am 1. April 1944 standen bei der Royal Air Force 5630 Bomber parat, 45 mehr als bei den amerikanischen Verbündeten.

II. This objective includes the densely populated residential area “east of the Altona train station, north of the Elbe and the park belt around the city center, south of Eimsbüttel, the most densely populated district. This one-and-a-half square mile target area is home to 190,000 people.”

III. This target includes the densely populated “residential areas in the northeastern part of the city. 140,000 people live in this one and one-half square mile target area.”

Five cities—Munich, Augsburg, Nuremberg, Stuttgart, and Karlsruhe—were to be approached from the Italian U.S. base at Foggia, about 100 kilometers north of Bari. All others—including Berlin, Cologne, Düsseldorf, Leipzig, and Dresden—from London.

Depending on climatic conditions, the more volatile phosgene or the heavier mustard would have been dropped. In the process, planners calculated the use of at least “100 planes with 4000 bombs of 100 pounds (mustard)” or “600 bombs of 1000 pounds (phosgene)” to poison “one square mile.”

America’s chemical factories had produced enough warfare agent; by the end of the war, 140,000 tons were stored in the arsenals. But there were not enough bombers ready at the time.

In a March 1944 attack, however, the American Air Forces could have completed 63 percent of the “target program,” and by June it could have completed 76 percent. It seems possible that the British would have flown along if necessary; on 1 April 1944, the Royal Air Force had 5630 bombers on standby, 45 more than their American allies.

[In a secret January 1945 recording, the German general Heinrich Kittel stated that the threat of Allied chemical weapons was to deter Germany from using the atomic bomb that it possessed (pp. 3786–3791).]

Stephen L. McFarland. 1997. *Battles Not Fought: The Creation of an Independent Air Force.* [https://www.usafa.edu/app/uploads/Harmon40.pdf]

The Joint Chiefs of Staff assigned the Army Air Forces to prepare for this battle that never took place. While B-17s and B-24s battled their way to Schweinfurt, Regensburg, Gotha, Heiterblick, Leipzig, and Berlin, hundreds of thousands of gas bombs were being stockpiled in England for what many thought was their inevitable use once the V-1s and V-2s began dropping out of the sky with a hiss, not a bang. The Allies would not strike first; Churchill and Roosevelt had already declared this. But if Germany did initiate chemical or biological warfare, the Allies would be ready to raise the ante. The Army Air Forces retaliatory plan, in conjunction with the Royal Air Force, identified Germany's thirty-eight largest cities for destruction with anticipation of killing upwards of twenty million people, making over one-half of Germany's urban area uninhabitable, and reducing industrial production by 60 percent. Ready in time for the Normandy invasion, 4,600 American heavy bombers then in the Eighth and Fifteenth Air Forces would launch a fifteen-day all-out blitz, each carrying a 75 percent mustard gas bomb load mixed with a 25 percent high explosive bomb load to help spread the gas. German civilians did not receive gas masks until late 1944 and then only for Nazi Party officials. Germany had no penicillin to fight the bacterial infections that would accompany the blistering effects of mustard gas. An average gas persistence of thirty days guaranteed a holocaust of unprecedented proportions.

R. V. Jones and J. M. Lewis. 1987. Churchill's Anthrax Bombs—A Debate. *Bulletin of the Atomic Scientists* 43:9:42–45. [https://www.julianlewis.net/essays-and-topics/2938:churchills-anthrax-bombs-a-debate-9]

In May 1981, a British television report by Robert Harris of the BBC made international headlines for alleging—wrongly, as it transpired—that Winston Churchill had advocated using anthrax against Nazi Germany in response to the 1944 V-weapon offensives. The truth was that he had pressed for consideration of the use of poison gas, but had reluctantly accepted the advice of his military advisers (the British Chiefs of Staff and their subordinate Joint Planning Staff) not to take such a step under the circumstances. He had not asked for the use of biological warfare to be considered, but, in reporting back to him negatively on the gas question, the Chiefs of Staff had added a brief examination of the biological warfare situation. As Bernstein rightly notes, this report pointed out that no use of anthrax would in any case be practicable as anthrax bombs were, as yet, unavailable. [...]

One of us (R.V. Jones) was present when Churchill put to the War Cabinet's Crossbow Committee, on 18 July 1944, his suggestion that Britain should attempt to deter the onset of the V.2 campaign by threatening the Germans with gas should they launch their rockets. Some of those present spoke firmly against it, and none spoke in favour.

[This article is important because R. V. Jones admitted that Churchill strongly advocated going ahead and dropping chemical weapons on Germany, even though Germany had not used weapons of mass destruction, which would have killed millions of civilians. However, this article appears to be incorrect about the anthrax. Please see the following pages for documentation on Churchill's plan to also drop five million anthrax "cakes" on German civilian targets.]

George Rosie. UK Planned to Wipe Out Germany with Anthrax: Allies' World War Two Shame. *Sunday Herald* (Glasgow) 14 October 2001, p. 2.

As the world recoils at the horrific possibility of al-Qaeda terrorists waging anthrax war against United States citizens, the *Sunday Herald* can reveal that Britain manufactured five million anthrax cattle cakes during the second world war and planned to drop them on Germany in 1944.

The aim of Operation Vegetarian was to wipe out the German beef and dairy herds and then see the bacterium spread to the human population. With people then having no access to antibiotics, this would have caused many thousands—perhaps even millions—of German men, women and children to suffer awful deaths.

The anthrax cakes were tested on Gruinard Island, off Wester Ross, which was finally cleared of contamination in 1990. Operation VEGETARIAN was planned for the summer of 1944 but, in the event, it was abandoned as the Allies' Normandy invasion progressed successfully.

Details of the wartime secret operation are contained in a series of War Office files (WO 188) at the Public Record Office in Kew. Some of the files are still classified. The man whose task was to carry out Operation Vegetarian was Dr Paul Fildes, director of the biology department at Porton Down near Salisbury in Wiltshire. Fildes had previously been in charge of the Medical Research Council's bacterial chemistry unit at Middlesex Hospital.

In early 1942, Fildes began searching Britain for suppliers and manufacturers of linseed-oil cattle cake to make five million small cakes. Large quantities of the bacillus itself had to be produced, while special containers to carry the cattle cakes had to be designed and made. Some RAF bombers had to be modified to deliver the anthrax-infected payload. And all of it had to be done as cheaply as possible.

The raw material for the cake was provided by the Olympia Oil and Cake Company in Blackburn. The contract to cut the cattle cake into small pieces went to J & E Atkinson of Bond Street in London, perfumers and toilet-soap manufacturers and suppliers to the royal family. The Atkinsons calculated that they could produce 180,000 to 250,000 cakes, each 2.5cm in diameter and 10 grammes in weight, in a 44-hour week. The price was to be between 12 and 15 shillings per thousand. The firm pledged to deliver 5,273,400 cakes by April 1943. By the middle of July 1942, the Atkinsons informed Fildes that 'we are now producing at the rate of 40,000 per day'.

The anthrax was manufactured by the Ministry of Agriculture and Fisheries at its veterinary laboratory in Surrey. An Oxford academic named Dr E Schuster was set to work devising the pump to inject the bacilli into the cattle cakes. The Porton Down scientists settled on cube-shaped cardboard containers, 18 cm square, to carry the infected foodstuff.

Each held 400 cakes. They would be fitted with a steel handle 'of a size which enables the operator to grasp the handle without difficulty when wearing thick leather or moleskin gloves...' Thirteen women were then recruited from various soap-making firms, sworn to secrecy and given the job of injecting the cattle cakes with anthrax spores.

At the same time, Fildes and his team were working on the best way to deliver the diseased cattle feed to the German herds.

The RAF's research unit came up with a simple solution—easily made wooden trays that fitted on to aircraft flare chutes. Their Bomber Command Lancasters, Halifaxes and Stirlings were chosen for the job.

By the beginning of 1944, Operation VEGETARIAN was ready to go. It was crucial to mount any attack in the summer months. Fildes said: 'The cattle must be caught in the open grazing fields when lush spring grass is on the wane.' 'Trials have shown that these tablets ... are found and consumed by the cattle in a very short time.' 'Cattle are concentrated in the northern half of Oldenburg and northwest Hanover. Aircraft flying to and from Berlin will fly over 60 miles of grazing land.'

Fildes calculated that, at an average ground speed of 300mph, the distance would be covered in 18 minutes. 'If one box of tablets is dispersed every two minutes, then each aircraft will be required to carry and disperse nine, or say 10, boxes.'

One Lancaster bomber returning from a raid on Berlin would be able to scatter 4000 anthrax-infected cakes over a 60-mile swathe in less than 20 minutes. A dozen aircraft would have been enough to litter most of the north German countryside with anthrax spores. Operation VEGETARIAN was a seriously deadly project.

But, by the time Fildes's operation was ready to go in the summer of 1944, the Normandy invasion had taken place and Allied armies were crashing through northern France and up through Italy. The war against Nazi Germany was instead being won by conventional means. At the end of 1945, five million anthrax-infected cattle cakes were incinerated in one of Porton Down's furnaces.

Werner Heisenberg, 6 August 1945. Quoted in: Farm Hall Report 4 [Bernstein 2001; Frank 1993; Hoffmann 2023].

About a year ago, I heard from SEGNER (?) from the Foreign Office that the Americans had threatened to drop a uranium bomb on Dresden if we didn't surrender soon. At that time I was asked whether I thought it possible, and, with complete conviction, I replied: "No."

Werner Heisenberg. 31 October 1963 letter to Ernst Brüche. Quoted in: Ernst Brüche. 1964. Was wußte man 1943/44 in Deutschland von der Atombombe? *Physikalische Blätter* 20:5:220–225. https://doi.org/10.1002/phbl.19640200504

Im Sommer 1944 (wahrscheinlich Anfang Juli) kam einmal der Adjutant von Göring zu mir mit der Mitteilung, es sei über die deutsche Vertretung in Lissabon eine amerikanische Drohung gegen die deutsche Regierung ausgesprochen worden, es werde innerhalb der nächsten sechs Wochen eine Atombombe über Dresden abgeworfen werden, wenn die Regierung nicht in irgendeiner Art um Frieden bäte. Über den genauen Inhalt der Bedingungen wurde mir nichts mitgeteilt. Ich wurde von dem Adjutanten Görings gefragt, ob ich es für möglich hielte, daß die Amerikaner bereits über eine Atombombe verfügten. Mir war diese Frage begreiflicherweise sehr unangenehm, weil mit der Antwort auf jeden Fall eine große Verantwortung verbunden war. Ich habe dann gesagt, daß ich es zwar für außerordentlich unwahrscheinlich, aber nicht für völlig unmöglich hielte, daß die Amerikaner zu diesem Zeitpunkt über eine solche Waffe verfügten, und habe versucht zu erklären, daß die Herstellung der Waffe auf jeden Fall einen enormen industriellen Aufwand erfordern müßte, von dem ich mir nicht denken könnte, daß die Amerikaner ihn schon geleistet hätten.

In the summer of 1944 (probably at the beginning of July) the adjutant of Goering once came to me with the information that an American threat had been made against the German government via the German representation in Lisbon that an atomic bomb would be dropped on Dresden within the next six weeks if the government did not ask for peace in some way. I was told nothing about the exact content of the conditions. I was asked by Goering's aide whether I thought it possible that the Americans already had an atomic bomb. I was understandably very uncomfortable with this question, because the answer was in any case connected with a great responsibility. I then said that I thought it extraordinarily improbable, but not entirely impossible, that the Americans had such a weapon at that time, and tried to explain that the production of the weapon would in any case require an enormous industrial effort which I could not imagine that the Americans had already made.

[Heisenberg's story is puzzling, since in July 1944 the U.S. was still a year away from its first completed atomic bomb.

The U.S. X-10 breeder reactor at Oak Ridge began operation in November 1943, and the first Hanford breeder reactor began operation in September 1944. Perhaps the information reported by Heisenberg was a U.S. threat to collect the fission products from those reactors and drop those on Dresden or other German cities as a radiological weapon. The reason for naming Dresden might be that it had been largely beyond the range of earlier Allied bombing, so it had been spared much damage to that date; thus the effects of a radiological attack on an otherwise relatively healthy city might be more obvious.

Heisenberg mentioned an Allied attack on Dresden that was threatened to occur around September 1944. A few months after that time, in February 1945, Allied bombers did indeed attack Dresden, but with conventional firebombs, killing over 20,000 German civilians.

If Heisenberg's report is accurate, it is interesting that the United States would threaten to attack a German city with a hastily constructed radiological weapon and call it a full-fledged atomic bomb, rather than threaten Germany with the very real Allied stockpiles of mustard and phosgene chemical weapons. The highly specific nature of this U.S. threat suggests that it was intended to counter an equally specific German threat: the use of German atomic bombs against one or more Allied targets. See Section D.13 for much more information.

Thus the German and Allied threats and counter-threats with chemical, biological, and nuclear weapons of mass destruction all appear to have been interrelated. This specter of mutual assured destruction (MAD) seems to have continually loomed over the final years of World War II. History books on the war should do a far better job of exploring and explaining this important aspect of the war, as well as how this threat profoundly influenced how all of the more visible aspects of the war played out.

Appendix B

Advanced Creations in Electrical Engineering

Die polnischen Juden machen nach gewissen gesprochen Gebeten und gehaltenen Fasttägen, die Gestalt eines Menschen aus Thon oder Leimen, und wenn sie das wunderkräftige Schemhamphoras darüber sprechen, so muß er lebendig werden. Reden kann er zwar nicht, versteht aber ziemlich was man spricht und befiehlt. Sie heißen ihn Golem, und brauchen ihn zu einem Aufwärter, allerley Hausarbeit zu verrichten, allein er darf nimmer aus dem Hause gehen. An seiner Stirn steht geschrieben *aemaeth* (Wahrheit, Gott) er nimmt aber täglich zu, und wird leicht größer und stärker denn alle Hausgenossen, so klein er anfangs gewesen ist. Daher sie aus Furcht vor ihm den ersten Buchstaben auslöschen, so daß nichts bleibt als *maeth* (er ist todt) worauf er zusammenfällt und wiederum in Ton aufgelöst wird.

The Polish Jews, after speaking certain prayers and observing fast days, made the figure of a man out of clay or loam, and when they speak the miracle-working Schemhamphoras over it, the figure comes alive. It is true that he cannot speak, but he understands reasonably well what anyone says to him and commands him to do. They call him Golem and use him as a servant to do all sorts of housework, but he may never leave the house alone. On his forehead is written *Aemaeth* (Truth, God). However, he increases in size daily and easily becomes larger and stronger than all his housemates, regardless of how small he was at first. Therefore, fearing him, they rub out the first letter, so that nothing remains but *Maeth* (he is dead), whereupon he collapses and is dissolved again into clay.

Jakob Grimm. 1808. *Zeitung für Einsiedler* [*Journal for Hermits*] No. 7, 23 April.
English translation by Edan Dekel and David Gantt Gurley.

German-speaking research groups designed and developed revolutionary microelectronics technologies years before those technologies were officially "invented" at Bell Laboratories and other non-German firms.

This appendix presents documentary evidence for:

B.1. The invention of transistors by German-speaking creators.

B.2. The invention of printed circuits/multi-pin connectors by German-speaking creators.

B.3. The invention of integrated circuits by German-speaking creators.

B.4. The invention of light emitting diodes (LEDs) by German-speaking creators.

B.5. The transfer of those technologies to other countries and companies.

Much more archival research is needed to clarify the historical details for the development and transfer of microelectronics technologies.

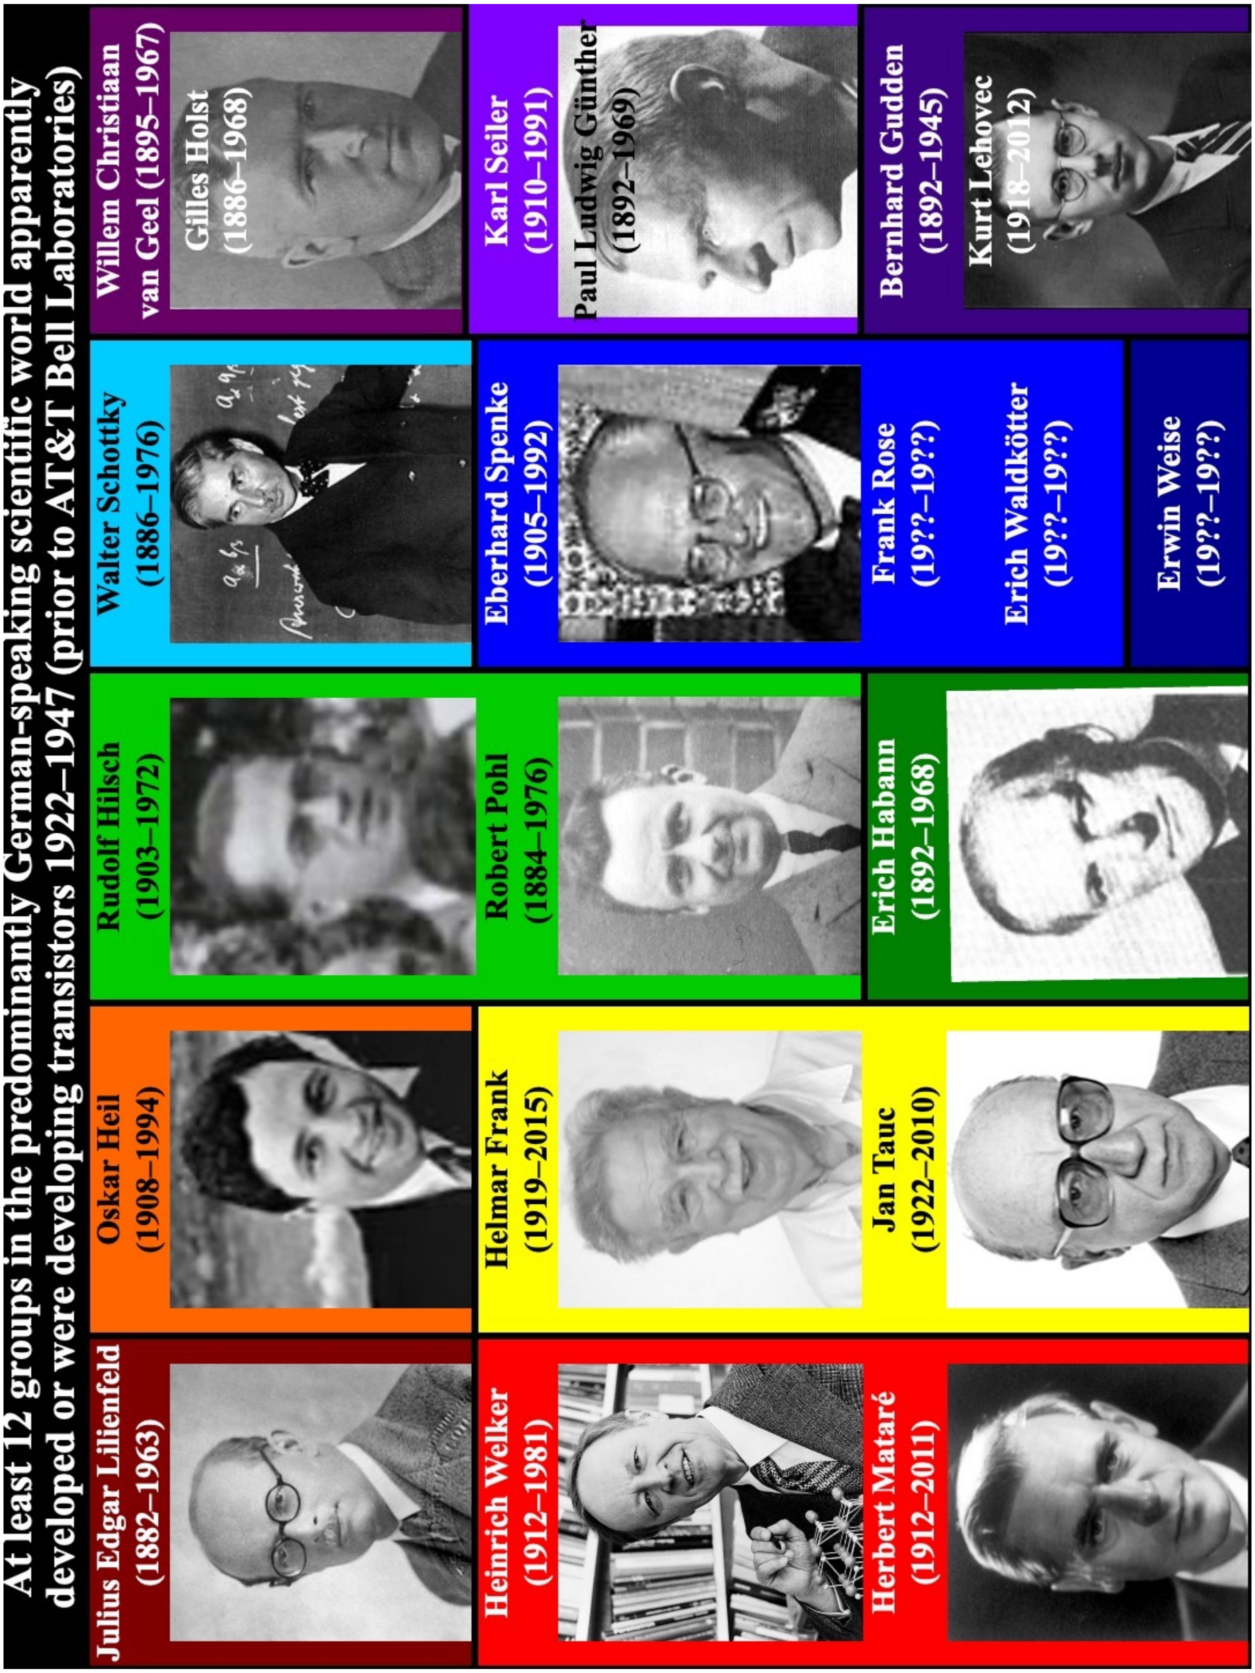
B.1 Transistors

[According to official histories, the first transistor was invented in the United States at AT&T Bell Telephone Laboratories in late 1947 and early 1948 by John Bardeen (American, 1908–1991), Walter Brattain (American, 1902–1987), and William Shockley (American, 1910–1989).

However, there is evidence that transistors were actually developed (or under development) earlier by at least 12 independent groups in the predominantly German-speaking research world that were led by the following scientists (Fig. B.1):

1. Julius Edgar Lilienfeld (Austrian, 1882–1963)
2. Oskar Heil (German, 1908–1994)
3. Gilles Holst (Dutch, 1886–1968) and Willem Christiaan van Geel (Dutch, 1895–1967)
4. Rudolf Hilsch (German, 1903–1972) and Robert Pohl (German, 1884–1976)
5. Erich Habann (German, 1892–1968)
6. Walter Schottky (Swiss/German, 1886–1976)
7. Heinrich Welker (German, 1912–1981) and Herbert Mataré (German, 1912–2011)
8. Erwin Weise (German?, 19??–19??)
9. Frank Rose (German?, 19??–19??), Eberhard Spenke (German, 1905–1992), and Erich Waldkötter (German?, 19??–19??)
10. Karl Seiler (German, 1910–1991) and Paul Ludwig Günther (German, 1892–1969)
11. Helmar Frank (Moravian, 1919–2015) and Jan Tauc (Bohemian, 1922–2010)
12. Bernhard Gudden (German, 1892–1945) and Kurt Lehovec (Bohemian/Austrian/Czech, 1918–2012)

In addition to these 12 groups, were there any other German-speaking groups developing transistors, for example at laboratories run by AEG, Askania, Blaupunkt, Fernseh, Loewe Radio, C. Lorenz, Philips, the Reichspost, Siemens, the SS, Telefunken, various universities, or other laboratories in Germany, Austria, Czech territory, Polish territory, or elsewhere? Much more archival research is needed in this area.]



At least 12 groups in the predominantly German-speaking scientific world apparently developed or were developing transistors 1922–1947 (prior to AT&T Bell Laboratories)
Julius Edgar Lilienfeld (1882–1963)
Oskar Heil (1908–1994)
Rudolf Hilsch (1903–1972)
Walter Schottky (1886–1976)
Willem Christiaan van Geel (1895–1967)
Gilles Holst (1886–1968)
Heinrich Welker (1912–1981)
Helmar Frank (1919–2015)
Robert Pohl (1884–1976)
Eberhard Spenke (1905–1992)
Karl Seiler (1910–1991)
Paul Ludwig Günther (1892–1969)
Herbert Mataré (1912–2011)
Jan Tauc (1922–2010)
Erich Habann (1892–1968)
Frank Rose (19??–19??)
Erich Waldkötter (19??–19??)
Erwin Weise (19??–19??)
Bernhard Gudden (1892–1945)
Kurt Lehovec (1918–2012)

Figure B.1: At least 12 groups in the predominantly German-speaking scientific world apparently developed or were developing transistors 1922–1947 (prior to AT&T Bell Laboratories).

[**1. Julius Edgar Lilienfeld (Austrian, 1882–1963)** filed several patent applications on a field effect transistor during the period 1925–1928, including:

> Julius Edgar Lilienfeld. Filed in 1925 in Canada and in 1926 in the United States. U.S. Patent 1,745,175. Method and Apparatus for Controlling Electric Currents. (pp. 2657–2660)
>
> Julius Edgar Lilienfeld. Filed in 1928. U.S. Patent 1,900,018. Device for Controlling Electric Current. (pp. 2661–2670)
>
> Julius Edgar Lilienfeld. Filed in 1928. U.S. Patent 1,877,140. Amplifier for Electric Currents. (pp. 2671–2677)

The great level of detail in those applications regarding the production and performance of such transistors strongly suggests that he built and tested them [Arns 1998; Crawford 1991], although exactly what results he achieved are not clear from currently available documents.

Much later, Bell Laboratories secretly built fully functioning devices based directly on Lilienfeld's patents, lending further support to the view that the patents were based on Lilienfeld's own successful experimentation [Arns 1998; Shockley and Pearson 1948].

In the 1920s, Lilienfeld moved to the United States, where he married an American woman. It appears that he was unsuccessful in finding sufficient financial and political support for his transistor approach in the United States. In the 1930s, Lilienfeld and his wife moved to the island of Saint Thomas in the Caribbean, where they lived the rest of their lives.]

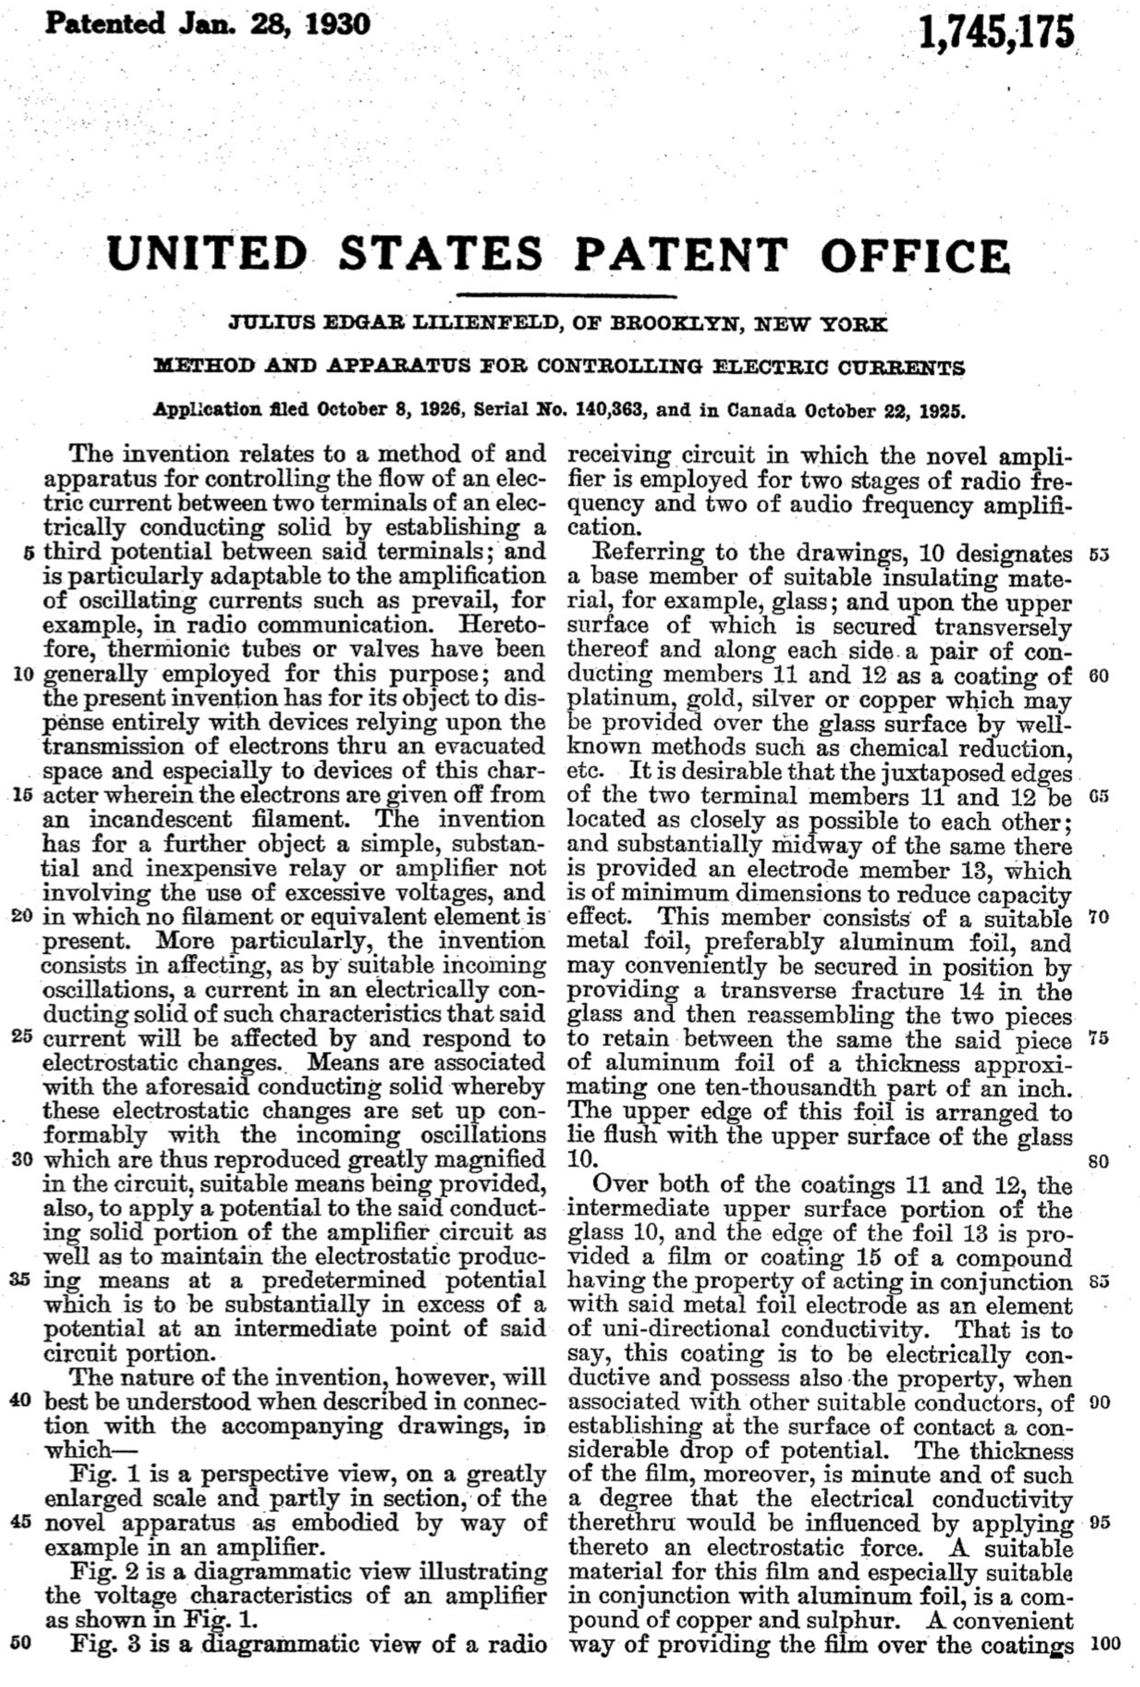
ATTORNEY

Figure B.2: Julius Edgar Lilienfeld filed a number of highly detailed patent applications on field effect transistors, including U.S. Patent 1,745,175 (originally filed in 1925 in Canada).



Patented Jan. 28, 1930 **1,745,175**

UNITED STATES PATENT OFFICE

JULIUS EDGAR LILIENFELD, OF BROOKLYN, NEW YORK

METHOD AND APPARATUS FOR CONTROLLING ELECTRIC CURRENTS

Application filed October 8, 1926, Serial No. 140,363, and in Canada October 22, 1925.

The invention relates to a method of and apparatus for controlling the flow of an electric current between two terminals of an electrically conducting solid by establishing a third potential between said terminals; and is particularly adaptable to the amplification of oscillating currents such as prevail, for example, in radio communication. Heretofore, thermionic tubes or valves have been generally employed for this purpose; and the present invention has for its object to dispense entirely with devices relying upon the transmission of electrons thru an evacuated space and especially to devices of this character wherein the electrons are given off from an incandescent filament. The invention has for a further object a simple, substantial and inexpensive relay or amplifier not involving the use of excessive voltages, and in which no filament or equivalent element is present. More particularly, the invention consists in affecting, as by suitable incoming oscillations, a current in an electrically conducting solid of such characteristics that said current will be affected by and respond to electrostatic changes. Means are associated with the aforesaid conducting solid whereby these electrostatic changes are set up conformably with the incoming oscillations which are thus reproduced greatly magnified in the circuit, suitable means being provided, also, to apply a potential to the said conducting solid portion of the amplifier circuit as well as to maintain the electrostatic producing means at a predetermined potential which is to be substantially in excess of a potential at an intermediate point of said circuit portion.

The nature of the invention, however, will best be understood when described in connection with the accompanying drawings, in which—

Fig. 1 is a perspective view, on a greatly enlarged scale and partly in section, of the novel apparatus as embodied by way of example in an amplifier.

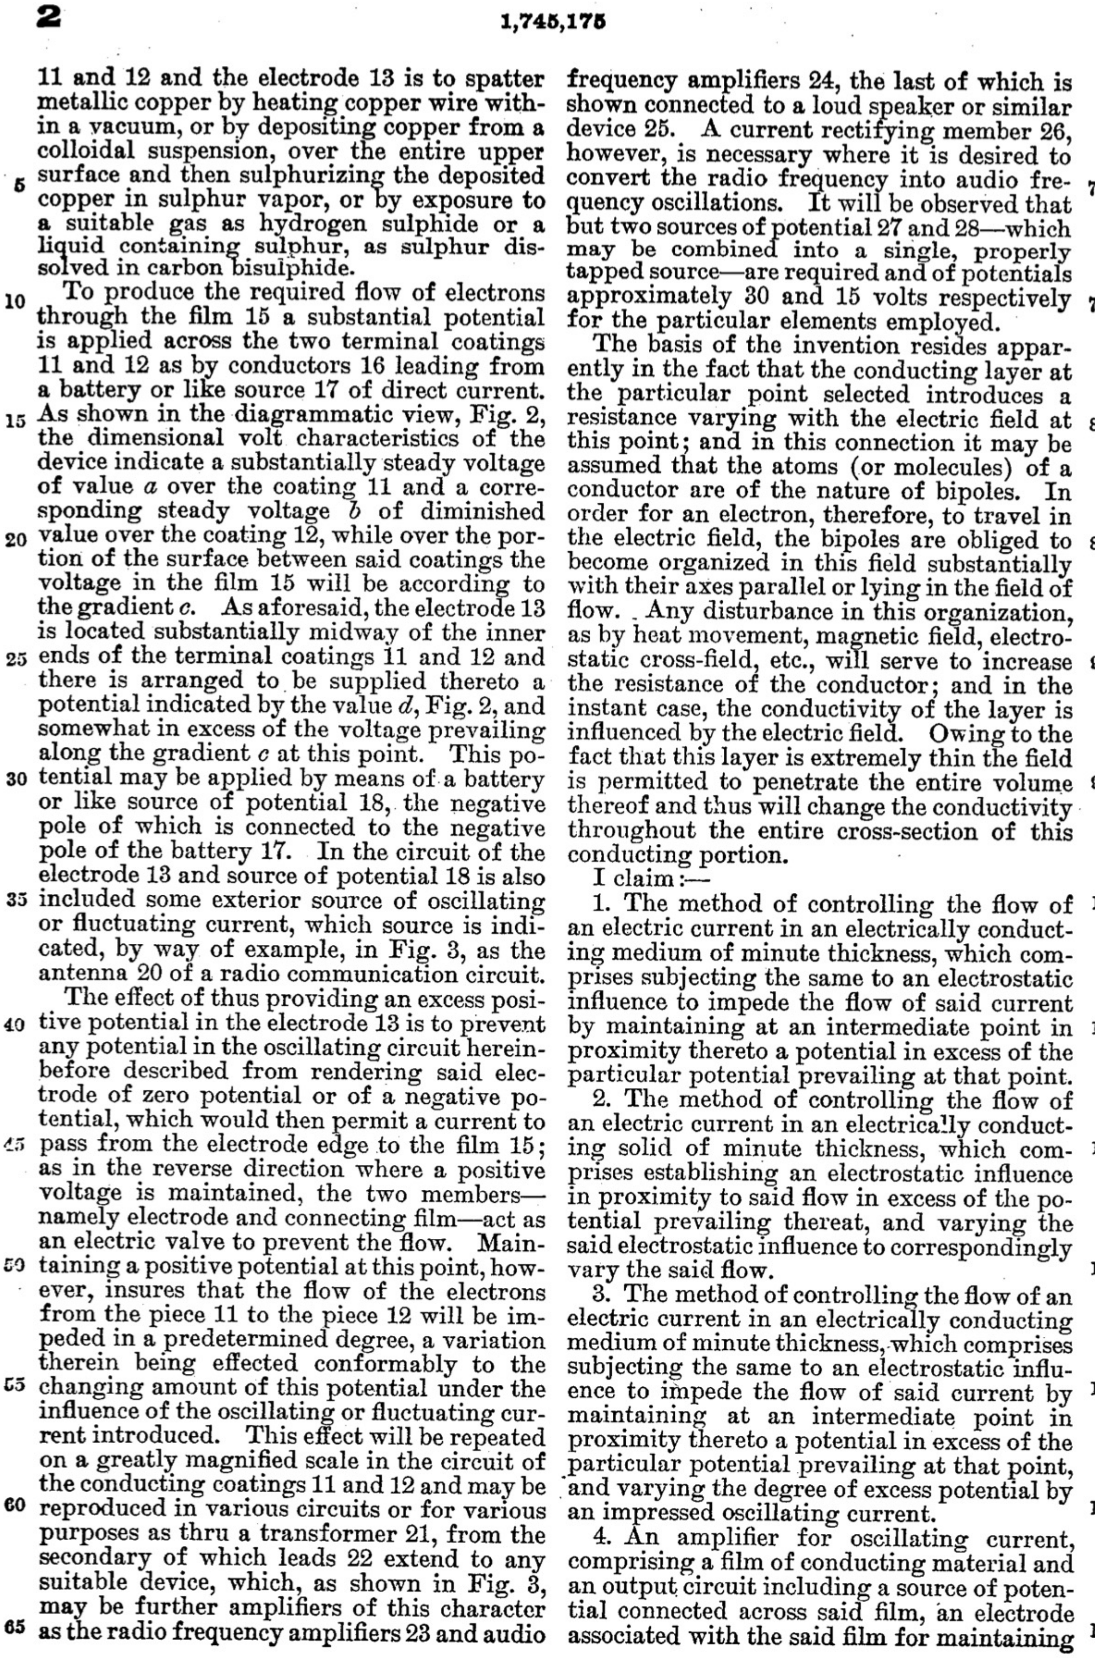
Fig. 2 is a diagrammatic view illustrating the voltage characteristics of an amplifier as shown in Fig. 1.

Fig. 3 is a diagrammatic view of a radio receiving circuit in which the novel amplifier is employed for two stages of radio frequency and two of audio frequency amplification.

Referring to the drawings, 10 designates a base member of suitable insulating material, for example, glass; and upon the upper surface of which is secured transversely thereof and along each side a pair of conducting members 11 and 12 as a coating of platinum, gold, silver or copper which may be provided over the glass surface by well-known methods such as chemical reduction, etc. It is desirable that the juxtaposed edges of the two terminal members 11 and 12 be located as closely as possible to each other; and substantially midway of the same there is provided an electrode member 13, which is of minimum dimensions to reduce capacity effect. This member consists of a suitable metal foil, preferably aluminum foil, and may conveniently be secured in position by providing a transverse fracture 14 in the glass and then reassembling the two pieces to retain between the same the said piece of aluminum foil of a thickness approximating one ten-thousandth part of an inch. The upper edge of this foil is arranged to lie flush with the upper surface of the glass 10.

Over both of the coatings 11 and 12, the intermediate upper surface portion of the glass 10, and the edge of the foil 13 is provided a film or coating 15 of a compound having the property of acting in conjunction with said metal foil electrode as an element of uni-directional conductivity. That is to say, this coating is to be electrically conductive and possess also the property, when associated with other suitable conductors, of establishing at the surface of contact a considerable drop of potential. The thickness of the film, moreover, is minute and of such a degree that the electrical conductivity therethru would be influenced by applying thereto an electrostatic force. A suitable material for this film and especially suitable in conjunction with aluminum foil, is a compound of copper and sulphur. A convenient way of providing the film over the coatings

Figure B.3: Julius Edgar Lilienfeld filed a number of highly detailed patent applications on field effect transistors, including U.S. Patent 1,745,175 (originally filed in 1925 in Canada).



2 1,745,175

11 and 12 and the electrode 13 is to spatter metallic copper by heating copper wire within a vacuum, or by depositing copper from a colloidal suspension, over the entire upper surface and then sulphurizing the deposited copper in sulphur vapor, or by exposure to a suitable gas as hydrogen sulphide or a liquid containing sulphur, as sulphur dissolved in carbon bisulphide.

To produce the required flow of electrons through the film 15 a substantial potential is applied across the two terminal coatings 11 and 12 as by conductors 16 leading from a battery or like source 17 of direct current. As shown in the diagrammatic view, Fig. 2, the dimensional volt characteristics of the device indicate a substantially steady voltage of value *a* over the coating 11 and a corresponding steady voltage *b* of diminished value over the coating 12, while over the portion of the surface between said coatings the voltage in the film 15 will be according to the gradient *c*. As aforesaid, the electrode 13 is located substantially midway of the inner ends of the terminal coatings 11 and 12 and there is arranged to be supplied thereto a potential indicated by the value *d*, Fig. 2, and somewhat in excess of the voltage prevailing along the gradient *c* at this point. This potential may be applied by means of a battery or like source of potential 18, the negative pole of which is connected to the negative pole of the battery 17. In the circuit of the electrode 13 and source of potential 18 is also included some exterior source of oscillating or fluctuating current, which source is indicated, by way of example, in Fig. 3, as the antenna 20 of a radio communication circuit.

The effect of thus providing an excess positive potential in the electrode 13 is to prevent any potential in the oscillating circuit hereinbefore described from rendering said electrode of zero potential or of a negative potential, which would then permit a current to pass from the electrode edge to the film 15; as in the reverse direction where a positive voltage is maintained, the two members—namely electrode and connecting film—act as an electric valve to prevent the flow. Maintaining a positive potential at this point, however, insures that the flow of the electrons from the piece 11 to the piece 12 will be impeded in a predetermined degree, a variation therein being effected conformably to the changing amount of this potential under the influence of the oscillating or fluctuating current introduced. This effect will be repeated on a greatly magnified scale in the circuit of the conducting coatings 11 and 12 and may be reproduced in various circuits or for various purposes as thru a transformer 21, from the secondary of which leads 22 extend to any suitable device, which, as shown in Fig. 3, may be further amplifiers of this character as the radio frequency amplifiers 23 and audio frequency amplifiers 24, the last of which is shown connected to a loud speaker or similar device 25. A current rectifying member 26, however, is necessary where it is desired to convert the radio frequency into audio frequency oscillations. It will be observed that but two sources of potential 27 and 28—which may be combined into a single, properly tapped source—are required and of potentials approximately 30 and 15 volts respectively for the particular elements employed.

The basis of the invention resides apparently in the fact that the conducting layer at the particular point selected introduces a resistance varying with the electric field at this point; and in this connection it may be assumed that the atoms (or molecules) of a conductor are of the nature of bipoles. In order for an electron, therefore, to travel in the electric field, the bipoles are obliged to become organized in this field substantially with their axes parallel or lying in the field of flow. Any disturbance in this organization, as by heat movement, magnetic field, electrostatic cross-field, etc., will serve to increase the resistance of the conductor; and in the instant case, the conductivity of the layer is influenced by the electric field. Owing to the fact that this layer is extremely thin the field is permitted to penetrate the entire volume thereof and thus will change the conductivity throughout the entire cross-section of this conducting portion.

I claim:—

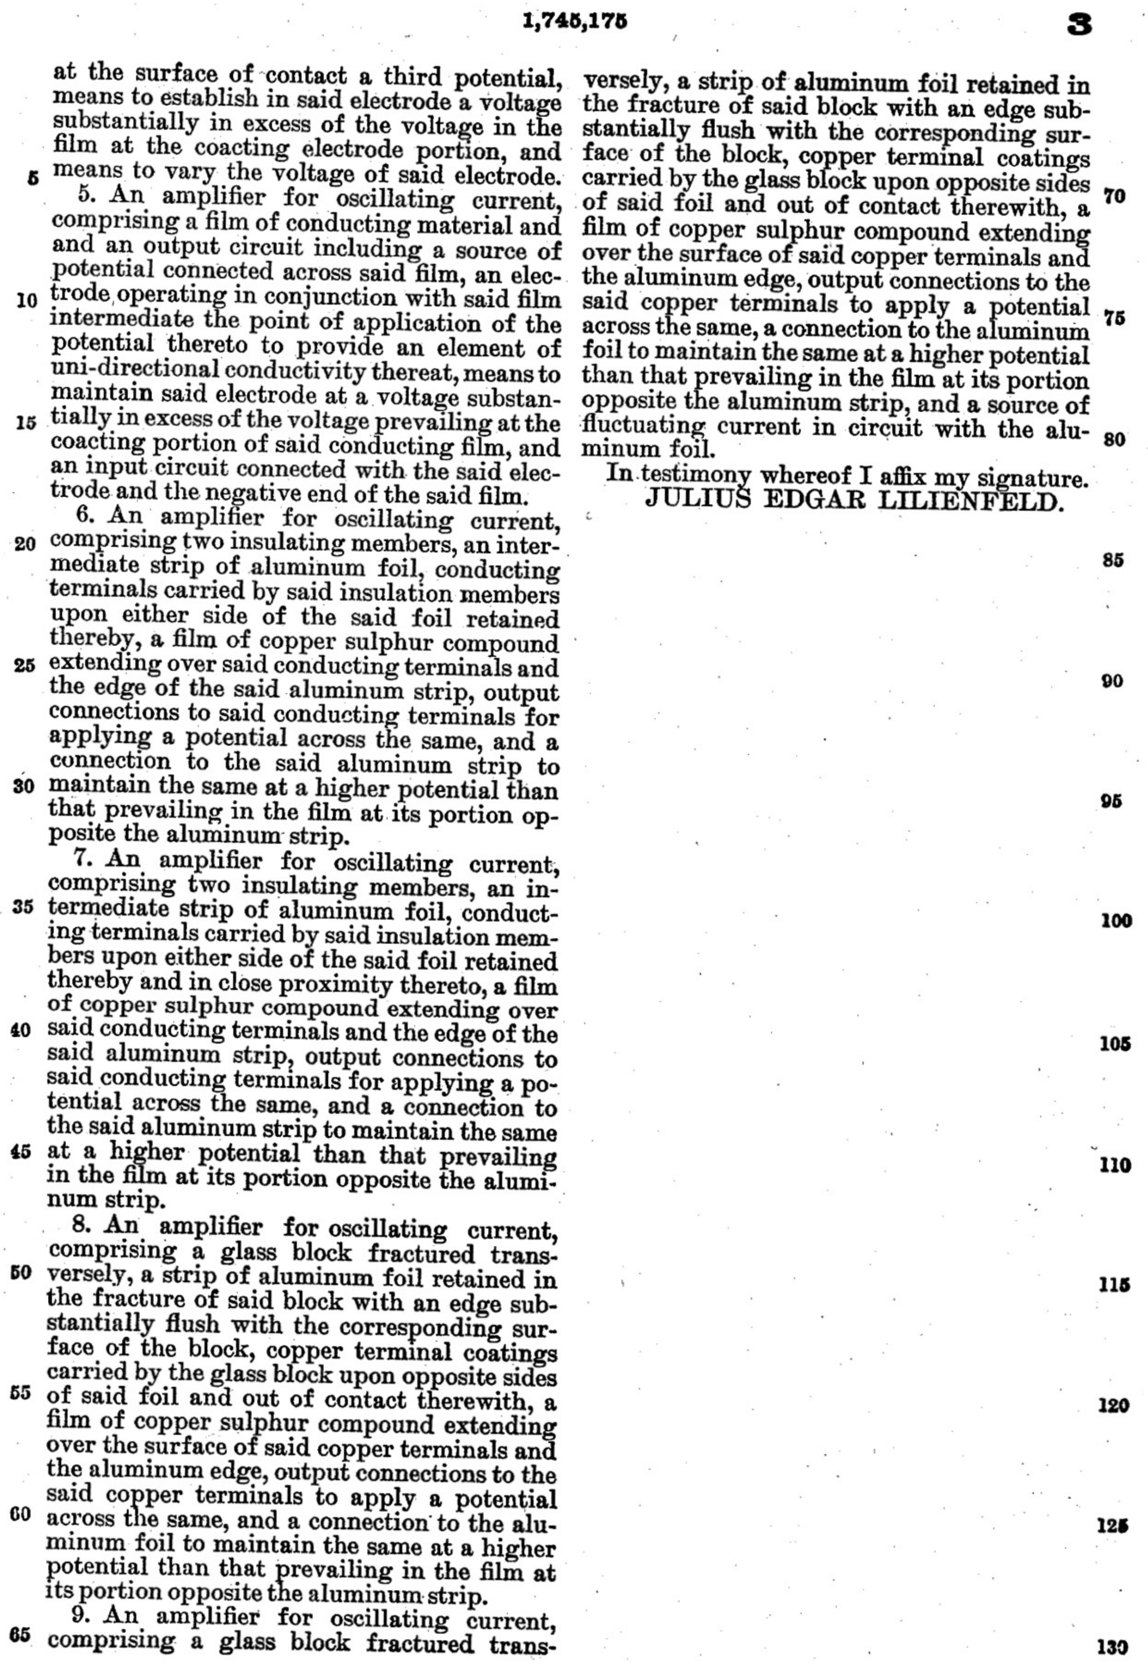
1. The method of controlling the flow of an electric current in an electrically conducting medium of minute thickness, which comprises subjecting the same to an electrostatic influence to impede the flow of said current by maintaining at an intermediate point in proximity thereto a potential in excess of the particular potential prevailing at that point.

2. The method of controlling the flow of an electric current in an electrically conducting solid of minute thickness, which comprises establishing an electrostatic influence in proximity to said flow in excess of the potential prevailing thereat, and varying the said electrostatic influence to correspondingly vary the said flow.

3. The method of controlling the flow of an electric current in an electrically conducting medium of minute thickness, which comprises subjecting the same to an electrostatic influence to impede the flow of said current by maintaining at an intermediate point in proximity thereto a potential in excess of the particular potential prevailing at that point, and varying the degree of excess potential by an impressed oscillating current.

4. An amplifier for oscillating current, comprising a film of conducting material and an output circuit including a source of potential connected across said film, an electrode associated with the said film for maintaining

Figure B.4: Julius Edgar Lilienfeld filed a number of highly detailed patent applications on field effect transistors, including U.S. Patent 1,745,175 (originally filed in 1925 in Canada).



1,745,175 **3**

at the surface of contact a third potential, means to establish in said electrode a voltage substantially in excess of the voltage in the film at the coacting electrode portion, and means to vary the voltage of said electrode.

5. An amplifier for oscillating current, comprising a film of conducting material and and an output circuit including a source of potential connected across said film, an electrode operating in conjunction with said film intermediate the point of application of the potential thereto to provide an element of uni-directional conductivity thereat, means to maintain said electrode at a voltage substantially in excess of the voltage prevailing at the coacting portion of said conducting film, and an input circuit connected with the said electrode and the negative end of the said film.

6. An amplifier for oscillating current, comprising two insulating members, an intermediate strip of aluminum foil, conducting terminals carried by said insulation members upon either side of the said foil retained thereby, a film of copper sulphur compound extending over said conducting terminals and the edge of the said aluminum strip, output connections to said conducting terminals for applying a potential across the same, and a connection to the said aluminum strip to maintain the same at a higher potential than that prevailing in the film at its portion opposite the aluminum strip.

7. An amplifier for oscillating current, comprising two insulating members, an intermediate strip of aluminum foil, conducting terminals carried by said insulation members upon either side of the said foil retained thereby and in close proximity thereto, a film of copper sulphur compound extending over said conducting terminals and the edge of the said aluminum strip, output connections to said conducting terminals for applying a potential across the same, and a connection to the said aluminum strip to maintain the same at a higher potential than that prevailing in the film at its portion opposite the aluminum strip.

8. An amplifier for oscillating current, comprising a glass block fractured transversely, a strip of aluminum foil retained in the fracture of said block with an edge substantially flush with the corresponding surface of the block, copper terminal coatings carried by the glass block upon opposite sides of said foil and out of contact therewith, a film of copper sulphur compound extending over the surface of said copper terminals and the aluminum edge, output connections to the said copper terminals to apply a potential across the same, and a connection to the aluminum foil to maintain the same at a higher potential than that prevailing in the film at its portion opposite the aluminum strip.

9. An amplifier for oscillating current, comprising a glass block fractured transversely, a strip of aluminum foil retained in the fracture of said block with an edge substantially flush with the corresponding surface of the block, copper terminal coatings carried by the glass block upon opposite sides of said foil and out of contact therewith, a film of copper sulphur compound extending over the surface of said copper terminals and the aluminum edge, output connections to the said copper terminals to apply a potential across the same, a connection to the aluminum foil to maintain the same at a higher potential than that prevailing in the film at its portion opposite the aluminum strip, and a source of fluctuating current in circuit with the aluminum foil.

In testimony whereof I affix my signature.

JULIUS EDGAR LILIENFELD.

UNITED STATES PATENT OFFICE

JULIUS EDGAR LILIENFELD, OF BROOKLYN, NEW YORK

DEVICE FOR CONTROLLING ELECTRIC CURRENT

Application filed March 28, 1928. Serial No. 265,372.

The invention relates to a device for use in connection with electric circuits, more particularly in the variation of the current characteristics thereof, for example, as a novel amplifier or rectifier (detector) element to be included in a suitable circuit.

It has for its object the provision of a simple, compact and substantial device of this character which withal shall be comparatively inexpensive to construct. The novel device may embody, for example, an amplifier in the use of which no filament heating or electron-producing means of this character are required, which device, moreover, may be operated under much lower voltage conditions than heretofore. Likewise, it is also adaptable to the rectification (detection) of oscillating currents.

If a coating of compounds of a metal, for example, the oxide of aluminum, magnesium, tantalum, tungsten, etc., be provided partly or entirely over a surface of the respective metal selected, or an alloy of several of these metals, an insulating layer having high dielectric properties may be attained; and I have discovered that an extremely intensive electric field may be established in a minute thickness of this layer, provided a further layer or coating of substantially more conductive material be integrally associated therewith by applying this material in disintegrated or finely subdivided state, e. g. by spraying or by spattering it cathodically in a vacuum from such metals as copper, lead, aluminum, etc., over said dielectric layer. Or, said layer may be applied by colloidal precipitation, it being understood that substantially molecular contact over the whole area is had between it and the dielectric layer.

Under these circumstances, such insulating layers, I also have discovered, do not possess the rectifying properties similar to those which are shown by different combinations, for example, when aluminum oxide is deposited on an aluminum electrode of an electrolytic cell with ammonium borate as electrolyte; on the contrary, the layers show insulating properties for voltages applied in either direction.

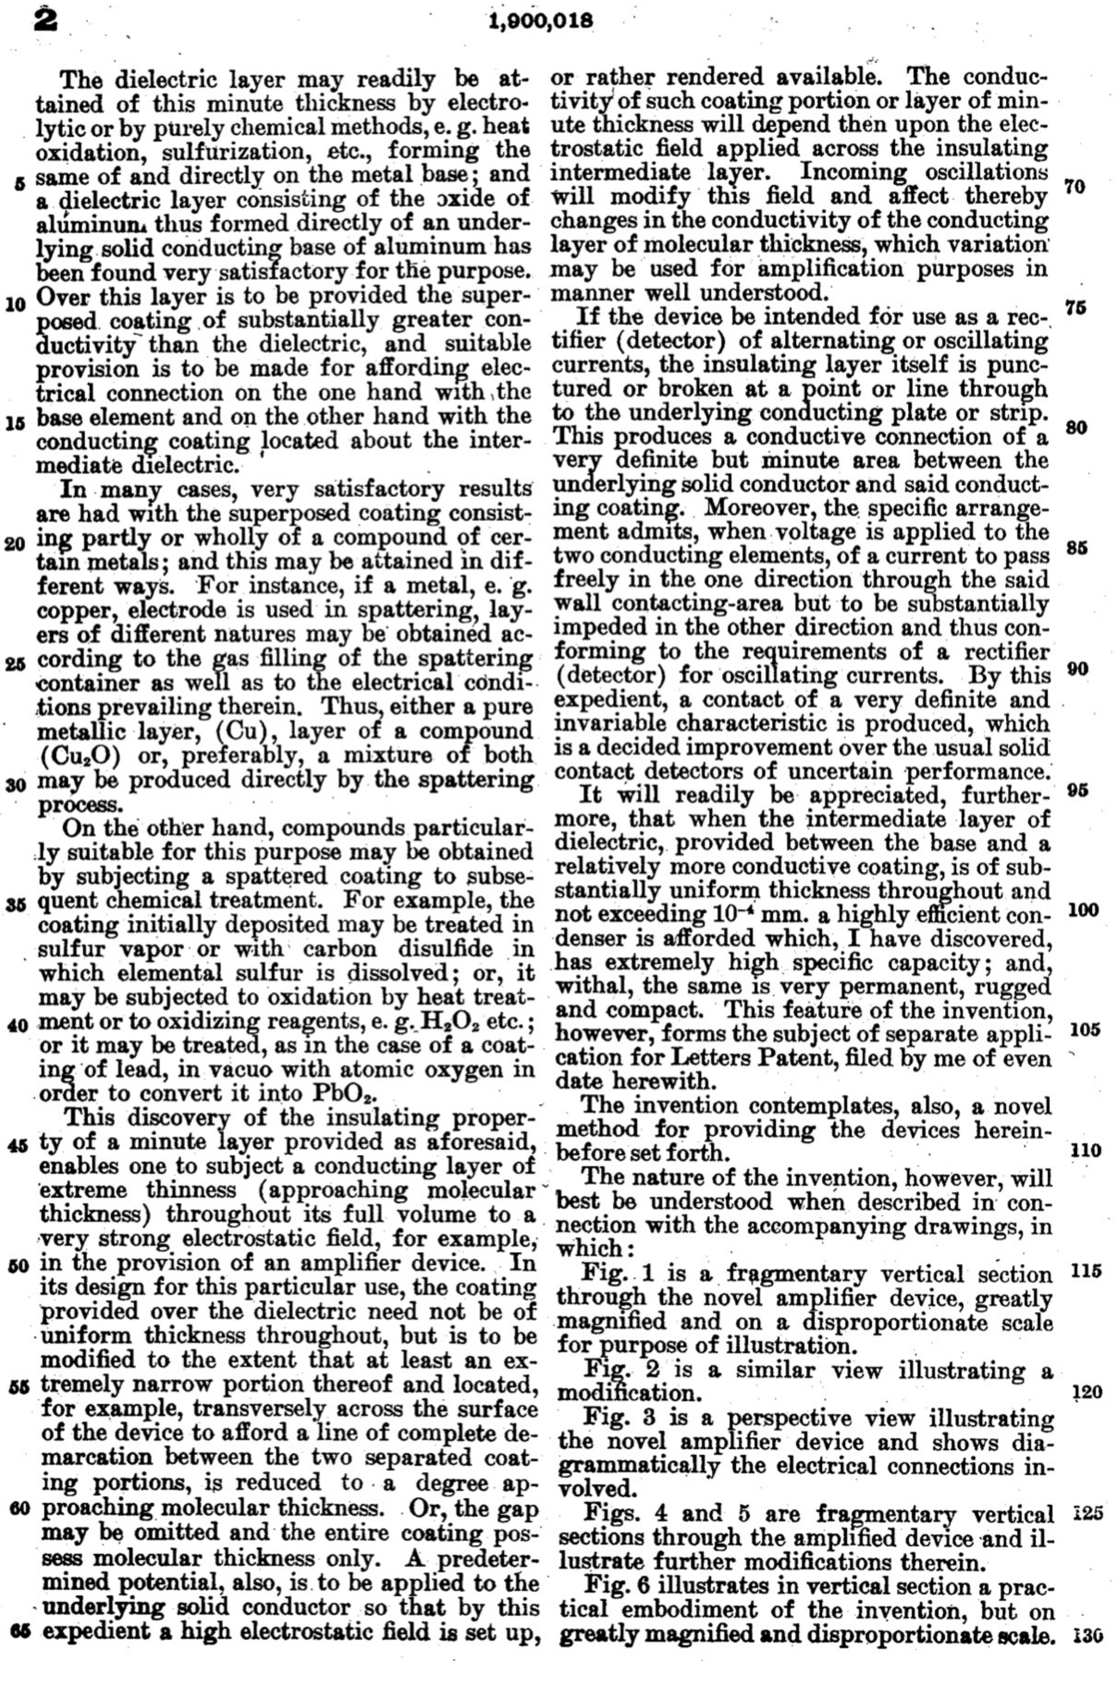
The underlying or base material is preferably of relatively thin metal, approximately 0.03 mm. or less to prevent, in case of bending distortion of the same and injury to the superposed layers.

In some cases it may be advisable to apply in succession in the manner indicated more than one coating partly or wholly over the first and insulating layer in order to increase the effectiveness of the insulation, a final coating of particularly good conducting quality, as of silver, platinum, tin, nickel, aluminum, etc., however, being generally provided so as to secure a good contact for the outside lead. These coatings, in particular as well as in certain instances also the initial coating, may be precipitated from colloidal metal suspensions; or they may be "metal sprayed."

The dielectric layer or layers when thus coated maintains its highly insulating property, affording a substantial insulation between the said underlying metal and the said coating or coatings; so that it is possible to apply voltages of the order of magnitude of 100 volts across a dielectric thus produced and of a thickness of the order of magnitude of only 10^{-4} mm. without puncturing it. In fact, the device will in many instances possess self-healing properties. In the aluminum-aluminum oxide embodiment with an oxidizable layer of copper, aluminum, magnesium, etc., short circuits will disappear as soon as the device is momentarily subjected to load.

This is a possible explanation of the fact, which I have discovered, that the allowable voltage appears to be a function not only of the nature and thickness of this dielectric layer but also of the physical and chemical properties of the superposed coatings. A coating produced by spattering from a copper cathode over the dielectric layer, for example, imparts to the layer the property of withstanding a higher voltage than silver similarly applied. These more effective coatings, however, may, in some cases, not be very highly conductive; and it is, therefore, sometimes desirable to provide more than one coating over the layer, the outer of them to possess a particularly good conducting quality and the same may be applied in any suitable manner, for example, electrolytically.

Figure B.9: Julius Edgar Lilienfeld filed a number of highly detailed patent applications on field effect transistors, including U.S. Patent 1,900,018 (filed in 1928).



2 1,900,018

The dielectric layer may readily be attained of this minute thickness by electrolytic or by purely chemical methods, e. g. heat oxidation, sulfurization, etc., forming the same of and directly on the metal base; and a dielectric layer consisting of the oxide of aluminum thus formed directly of an underlying solid conducting base of aluminum has been found very satisfactory for the purpose. Over this layer is to be provided the superposed coating of substantially greater conductivity than the dielectric, and suitable provision is to be made for affording electrical connection on the one hand with the base element and on the other hand with the conducting coating located about the intermediate dielectric.

In many cases, very satisfactory results are had with the superposed coating consisting partly or wholly of a compound of certain metals; and this may be attained in different ways. For instance, if a metal, e. g. copper, electrode is used in spattering, layers of different natures may be obtained according to the gas filling of the spattering container as well as to the electrical conditions prevailing therein. Thus, either a pure metallic layer, (Cu), layer of a compound (Cu_2O) or, preferably, a mixture of both may be produced directly by the spattering process.

On the other hand, compounds particularly suitable for this purpose may be obtained by subjecting a spattered coating to subsequent chemical treatment. For example, the coating initially deposited may be treated in sulfur vapor or with carbon disulfide in which elemental sulfur is dissolved; or, it may be subjected to oxidation by heat treatment or to oxidizing reagents, e. g. H_2O_2 etc.; or it may be treated, as in the case of a coating of lead, in vacuo with atomic oxygen in order to convert it into PbO_2.

This discovery of the insulating property of a minute layer provided as aforesaid, enables one to subject a conducting layer of extreme thinness (approaching molecular thickness) throughout its full volume to a very strong electrostatic field, for example, in the provision of an amplifier device. In its design for this particular use, the coating provided over the dielectric need not be of uniform thickness throughout, but is to be modified to the extent that at least an extremely narrow portion thereof and located, for example, transversely across the surface of the device to afford a line of complete demarcation between the two separated coating portions, is reduced to a degree approaching molecular thickness. Or, the gap may be omitted and the entire coating possess molecular thickness only. A predetermined potential, also, is to be applied to the underlying solid conductor so that by this expedient a high electrostatic field is set up, or rather rendered available. The conductivity of such coating portion or layer of minute thickness will depend then upon the electrostatic field applied across the insulating intermediate layer. Incoming oscillations will modify this field and affect thereby changes in the conductivity of the conducting layer of molecular thickness, which variation may be used for amplification purposes in manner well understood.

If the device be intended for use as a rectifier (detector) of alternating or oscillating currents, the insulating layer itself is punctured or broken at a point or line through to the underlying conducting plate or strip. This produces a conductive connection of a very definite but minute area between the underlying solid conductor and said conducting coating. Moreover, the specific arrangement admits, when voltage is applied to the two conducting elements, of a current to pass freely in the one direction through the said wall contacting-area but to be substantially impeded in the other direction and thus conforming to the requirements of a rectifier (detector) for oscillating currents. By this expedient, a contact of a very definite and invariable characteristic is produced, which is a decided improvement over the usual solid contact detectors of uncertain performance.

It will readily be appreciated, furthermore, that when the intermediate layer of dielectric, provided between the base and a relatively more conductive coating, is of substantially uniform thickness throughout and not exceeding 10^{-4} mm. a highly efficient condenser is afforded which, I have discovered, has extremely high specific capacity; and, withal, the same is very permanent, rugged and compact. This feature of the invention, however, forms the subject of separate application for Letters Patent, filed by me of even date herewith.

The invention contemplates, also, a novel method for providing the devices hereinbefore set forth.

The nature of the invention, however, will best be understood when described in connection with the accompanying drawings, in which:

Fig. 1 is a fragmentary vertical section through the novel amplifier device, greatly magnified and on a disproportionate scale for purpose of illustration.

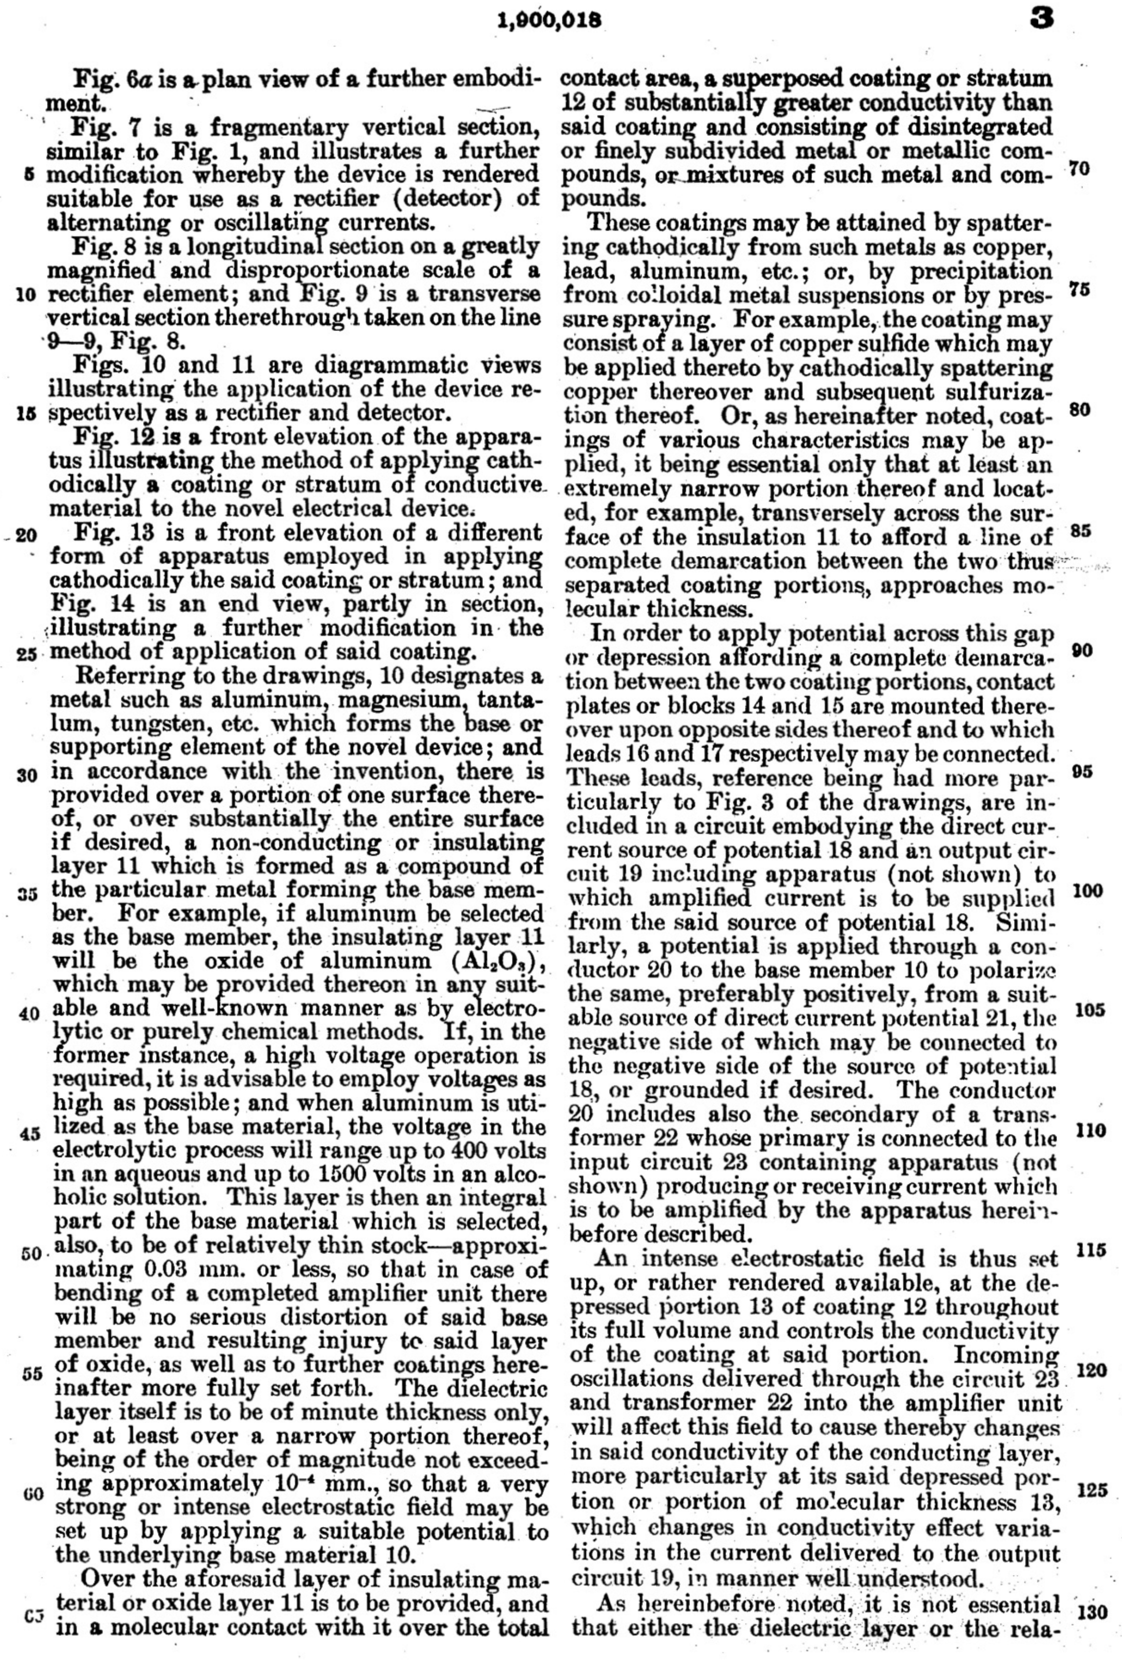
Fig. 2 is a similar view illustrating a modification.

Fig. 3 is a perspective view illustrating the novel amplifier device and shows diagrammatically the electrical connections involved.

Figs. 4 and 5 are fragmentary vertical sections through the amplified device and illustrate further modifications therein.

Fig. 6 illustrates in vertical section a practical embodiment of the invention, but on greatly magnified and disproportionate scale.

Figure B.10: Julius Edgar Lilienfeld filed a number of highly detailed patent applications on field effect transistors, including U.S. Patent 1,900,018 (filed in 1928).



1,900,018 **3**

Fig. 6*a* is a plan view of a further embodiment.

Fig. 7 is a fragmentary vertical section, similar to Fig. 1, and illustrates a further modification whereby the device is rendered suitable for use as a rectifier (detector) of alternating or oscillating currents.

Fig. 8 is a longitudinal section on a greatly magnified and disproportionate scale of a rectifier element; and Fig. 9 is a transverse vertical section therethrough taken on the line 9—9, Fig. 8.

Figs. 10 and 11 are diagrammatic views illustrating the application of the device respectively as a rectifier and detector.

Fig. 12 is a front elevation of the apparatus illustrating the method of applying cathodically a coating or stratum of conductive material to the novel electrical device.

Fig. 13 is a front elevation of a different form of apparatus employed in applying cathodically the said coating or stratum; and Fig. 14 is an end view, partly in section, illustrating a further modification in the method of application of said coating.

Referring to the drawings, 10 designates a metal such as aluminum, magnesium, tantalum, tungsten, etc. which forms the base or supporting element of the novel device; and in accordance with the invention, there is provided over a portion of one surface thereof, or over substantially the entire surface if desired, a non-conducting or insulating layer 11 which is formed as a compound of the particular metal forming the base member. For example, if aluminum be selected as the base member, the insulating layer 11 will be the oxide of aluminum (Al_2O_3), which may be provided thereon in any suitable and well-known manner as by electrolytic or purely chemical methods. If, in the former instance, a high voltage operation is required, it is advisable to employ voltages as high as possible; and when aluminum is utilized as the base material, the voltage in the electrolytic process will range up to 400 volts in an aqueous and up to 1500 volts in an alcoholic solution. This layer is then an integral part of the base material which is selected, also, to be of relatively thin stock—approximating 0.03 mm. or less, so that in case of bending of a completed amplifier unit there will be no serious distortion of said base member and resulting injury to said layer of oxide, as well as to further coatings hereinafter more fully set forth. The dielectric layer itself is to be of minute thickness only, or at least over a narrow portion thereof, being of the order of magnitude not exceeding approximately 10^{-4} mm., so that a very strong or intense electrostatic field may be set up by applying a suitable potential to the underlying base material 10.

Over the aforesaid layer of insulating material or oxide layer 11 is to be provided, and in a molecular contact with it over the total contact area, a superposed coating or stratum 12 of substantially greater conductivity than said coating and consisting of disintegrated or finely subdivided metal or metallic compounds, or mixtures of such metal and compounds.

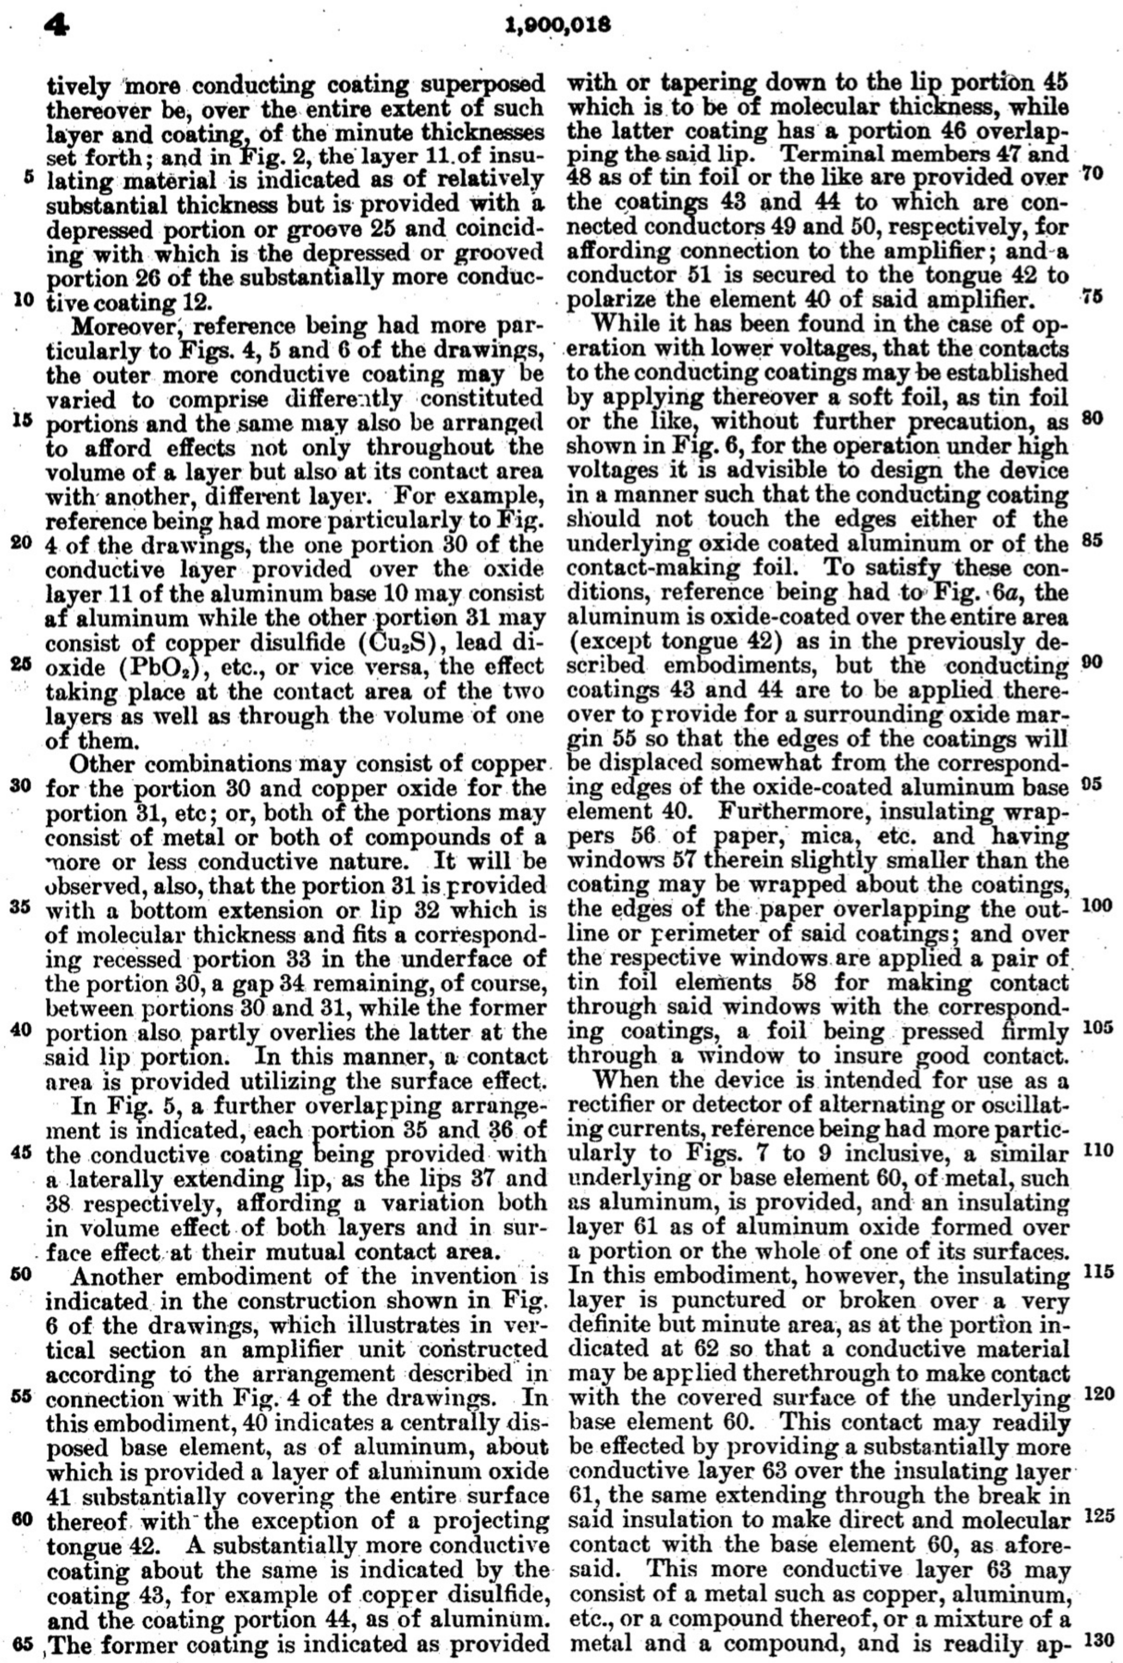
These coatings may be attained by spattering cathodically from such metals as copper, lead, aluminum, etc.; or, by precipitation from colloidal metal suspensions or by pressure spraying. For example, the coating may consist of a layer of copper sulfide which may be applied thereto by cathodically spattering copper thereover and subsequent sulfurization thereof. Or, as hereinafter noted, coatings of various characteristics may be applied, it being essential only that at least an extremely narrow portion thereof and located, for example, transversely across the surface of the insulation 11 to afford a line of complete demarcation between the two thus separated coating portions, approaches molecular thickness.

In order to apply potential across this gap or depression affording a complete demarcation between the two coating portions, contact plates or blocks 14 and 15 are mounted thereover upon opposite sides thereof and to which leads 16 and 17 respectively may be connected. These leads, reference being had more particularly to Fig. 3 of the drawings, are included in a circuit embodying the direct current source of potential 18 and an output circuit 19 including apparatus (not shown) to which amplified current is to be supplied from the said source of potential 18. Similarly, a potential is applied through a conductor 20 to the base member 10 to polarize the same, preferably positively, from a suitable source of direct current potential 21, the negative side of which may be connected to the negative side of the source of potential 18, or grounded if desired. The conductor 20 includes also the secondary of a transformer 22 whose primary is connected to the input circuit 23 containing apparatus (not shown) producing or receiving current which is to be amplified by the apparatus hereinbefore described.

An intense electrostatic field is thus set up, or rather rendered available, at the depressed portion 13 of coating 12 throughout its full volume and controls the conductivity of the coating at said portion. Incoming oscillations delivered through the circuit 23 and transformer 22 into the amplifier unit will affect this field to cause thereby changes in said conductivity of the conducting layer, more particularly at its said depressed portion or portion of molecular thickness 13, which changes in conductivity effect variations in the current delivered to the output circuit 19, in manner well understood.

As hereinbefore noted, it is not essential that either the dielectric layer or the rela-

Figure B.11: Julius Edgar Lilienfeld filed a number of highly detailed patent applications on field effect transistors, including U.S. Patent 1,900,018 (filed in 1928).



4 **1,900,018**

tively more conducting coating superposed thereover be, over the entire extent of such layer and coating, of the minute thicknesses set forth; and in Fig. 2, the layer 11 of insulating material is indicated as of relatively substantial thickness but is provided with a depressed portion or groove 25 and coinciding with which is the depressed or grooved portion 26 of the substantially more conductive coating 12.

Moreover, reference being had more particularly to Figs. 4, 5 and 6 of the drawings, the outer more conductive coating may be varied to comprise differently constituted portions and the same may also be arranged to afford effects not only throughout the volume of a layer but also at its contact area with another, different layer. For example, reference being had more particularly to Fig. 4 of the drawings, the one portion 30 of the conductive layer provided over the oxide layer 11 of the aluminum base 10 may consist af aluminum while the other portion 31 may consist of copper disulfide (Cu_2S), lead dioxide (PbO_2), etc., or vice versa, the effect taking place at the contact area of the two layers as well as through the volume of one of them.

Other combinations may consist of copper for the portion 30 and copper oxide for the portion 31, etc; or, both of the portions may consist of metal or both of compounds of a more or less conductive nature. It will be observed, also, that the portion 31 is provided with a bottom extension or lip 32 which is of molecular thickness and fits a corresponding recessed portion 33 in the underface of the portion 30, a gap 34 remaining, of course, between portions 30 and 31, while the former portion also partly overlies the latter at the said lip portion. In this manner, a contact area is provided utilizing the surface effect.

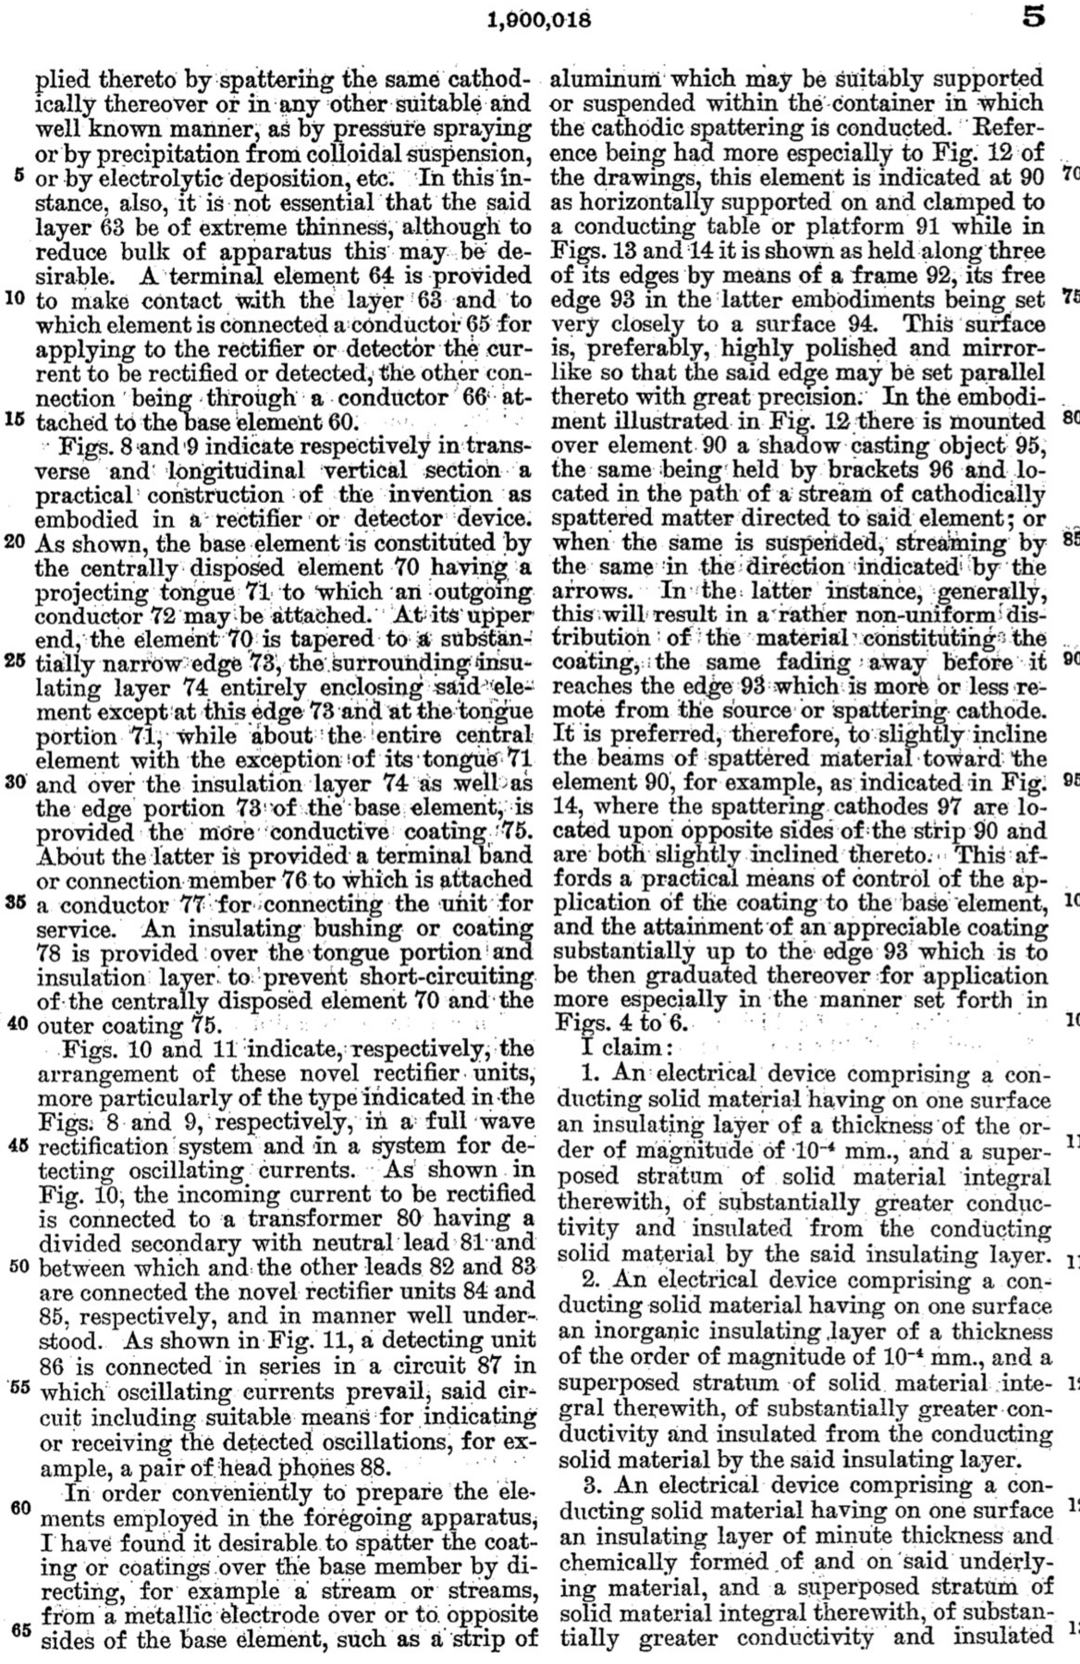
In Fig. 5, a further overlapping arrangement is indicated, each portion 35 and 36 of the conductive coating being provided with a laterally extending lip, as the lips 37 and 38 respectively, affording a variation both in volume effect of both layers and in surface effect at their mutual contact area.

Another embodiment of the invention is indicated in the construction shown in Fig. 6 of the drawings, which illustrates in vertical section an amplifier unit constructed according to the arrangement described in connection with Fig. 4 of the drawings. In this embodiment, 40 indicates a centrally disposed base element, as of aluminum, about which is provided a layer of aluminum oxide 41 substantially covering the entire surface thereof with the exception of a projecting tongue 42. A substantially more conductive coating about the same is indicated by the coating 43, for example of copper disulfide, and the coating portion 44, as of aluminum. The former coating is indicated as provided with or tapering down to the lip portion 45 which is to be of molecular thickness, while the latter coating has a portion 46 overlapping the said lip. Terminal members 47 and 48 as of tin foil or the like are provided over the coatings 43 and 44 to which are connected conductors 49 and 50, respectively, for affording connection to the amplifier; and a conductor 51 is secured to the tongue 42 to polarize the element 40 of said amplifier.

While it has been found in the case of operation with lower voltages, that the contacts to the conducting coatings may be established by applying thereover a soft foil, as tin foil or the like, without further precaution, as shown in Fig. 6, for the operation under high voltages it is advisible to design the device in a manner such that the conducting coating should not touch the edges either of the underlying oxide coated aluminum or of the contact-making foil. To satisfy these conditions, reference being had to Fig. 6*a*, the aluminum is oxide-coated over the entire area (except tongue 42) as in the previously described embodiments, but the conducting coatings 43 and 44 are to be applied thereover to provide for a surrounding oxide margin 55 so that the edges of the coatings will be displaced somewhat from the corresponding edges of the oxide-coated aluminum base element 40. Furthermore, insulating wrappers 56 of paper, mica, etc. and having windows 57 therein slightly smaller than the coating may be wrapped about the coatings, the edges of the paper overlapping the outline or perimeter of said coatings; and over the respective windows are applied a pair of tin foil elements 58 for making contact through said windows with the corresponding coatings, a foil being pressed firmly through a window to insure good contact.

When the device is intended for use as a rectifier or detector of alternating or oscillating currents, reference being had more particularly to Figs. 7 to 9 inclusive, a similar underlying or base element 60, of metal, such as aluminum, is provided, and an insulating layer 61 as of aluminum oxide formed over a portion or the whole of one of its surfaces. In this embodiment, however, the insulating layer is punctured or broken over a very definite but minute area, as at the portion indicated at 62 so that a conductive material may be applied therethrough to make contact with the covered surface of the underlying base element 60. This contact may readily be effected by providing a substantially more conductive layer 63 over the insulating layer 61, the same extending through the break in said insulation to make direct and molecular contact with the base element 60, as aforesaid. This more conductive layer 63 may consist of a metal such as copper, aluminum, etc., or a compound thereof, or a mixture of a metal and a compound, and is readily ap-

Figure B.12: Julius Edgar Lilienfeld filed a number of highly detailed patent applications on field effect transistors, including U.S. Patent 1,900,018 (filed in 1928).



1,900,018 5

plied thereto by spattering the same cathodically thereover or in any other suitable and well known manner, as by pressure spraying or by precipitation from colloidal suspension, or by electrolytic deposition, etc. In this instance, also, it is not essential that the said layer 63 be of extreme thinness, although to reduce bulk of apparatus this may be desirable. A terminal element 64 is provided to make contact with the layer 63 and to which element is connected a conductor 65 for applying to the rectifier or detector the current to be rectified or detected, the other connection being through a conductor 66 attached to the base element 60.

Figs. 8 and 9 indicate respectively in transverse and longitudinal vertical section a practical construction of the invention as embodied in a rectifier or detector device. As shown, the base element is constituted by the centrally disposed element 70 having a projecting tongue 71 to which an outgoing conductor 72 may be attached. At its upper end, the element 70 is tapered to a substantially narrow edge 73, the surrounding insulating layer 74 entirely enclosing said element except at this edge 73 and at the tongue portion 71, while about the entire central element with the exception of its tongue 71 and over the insulation layer 74 as well as the edge portion 73 of the base element, is provided the more conductive coating 75. About the latter is provided a terminal band or connection member 76 to which is attached a conductor 77 for connecting the unit for service. An insulating bushing or coating 78 is provided over the tongue portion and insulation layer to prevent short-circuiting of the centrally disposed element 70 and the outer coating 75.

Figs. 10 and 11 indicate, respectively, the arrangement of these novel rectifier units, more particularly of the type indicated in the Figs. 8 and 9, respectively, in a full wave rectification system and in a system for detecting oscillating currents. As shown in Fig. 10, the incoming current to be rectified is connected to a transformer 80 having a divided secondary with neutral lead 81 and between which and the other leads 82 and 83 are connected the novel rectifier units 84 and 85, respectively, and in manner well understood. As shown in Fig. 11, a detecting unit 86 is connected in series in a circuit 87 in which oscillating currents prevail, said circuit including suitable means for indicating or receiving the detected oscillations, for example, a pair of head phones 88.

In order conveniently to prepare the elements employed in the foregoing apparatus, I have found it desirable to spatter the coating or coatings over the base member by directing, for example a stream or streams, from a metallic electrode over or to opposite sides of the base element, such as a strip of aluminum which may be suitably supported or suspended within the container in which the cathodic spattering is conducted. Reference being had more especially to Fig. 12 of the drawings, this element is indicated at 90 as horizontally supported on and clamped to a conducting table or platform 91 while in Figs. 13 and 14 it is shown as held along three of its edges by means of a frame 92, its free edge 93 in the latter embodiments being set very closely to a surface 94. This surface is, preferably, highly polished and mirror-like so that the said edge may be set parallel thereto with great precision. In the embodiment illustrated in Fig. 12 there is mounted over element 90 a shadow casting object 95, the same being held by brackets 96 and located in the path of a stream of cathodically spattered matter directed to said element; or when the same is suspended, streaming by the same in the direction indicated by the arrows. In the latter instance, generally, this will result in a rather non-uniform distribution of the material constituting the coating, the same fading away before it reaches the edge 93 which is more or less remote from the source or spattering cathode. It is preferred, therefore, to slightly incline the beams of spattered material toward the element 90, for example, as indicated in Fig. 14, where the spattering cathodes 97 are located upon opposite sides of the strip 90 and are both slightly inclined thereto. This affords a practical means of control of the application of the coating to the base element, and the attainment of an appreciable coating substantially up to the edge 93 which is to be then graduated thereover for application more especially in the manner set forth in Figs. 4 to 6.

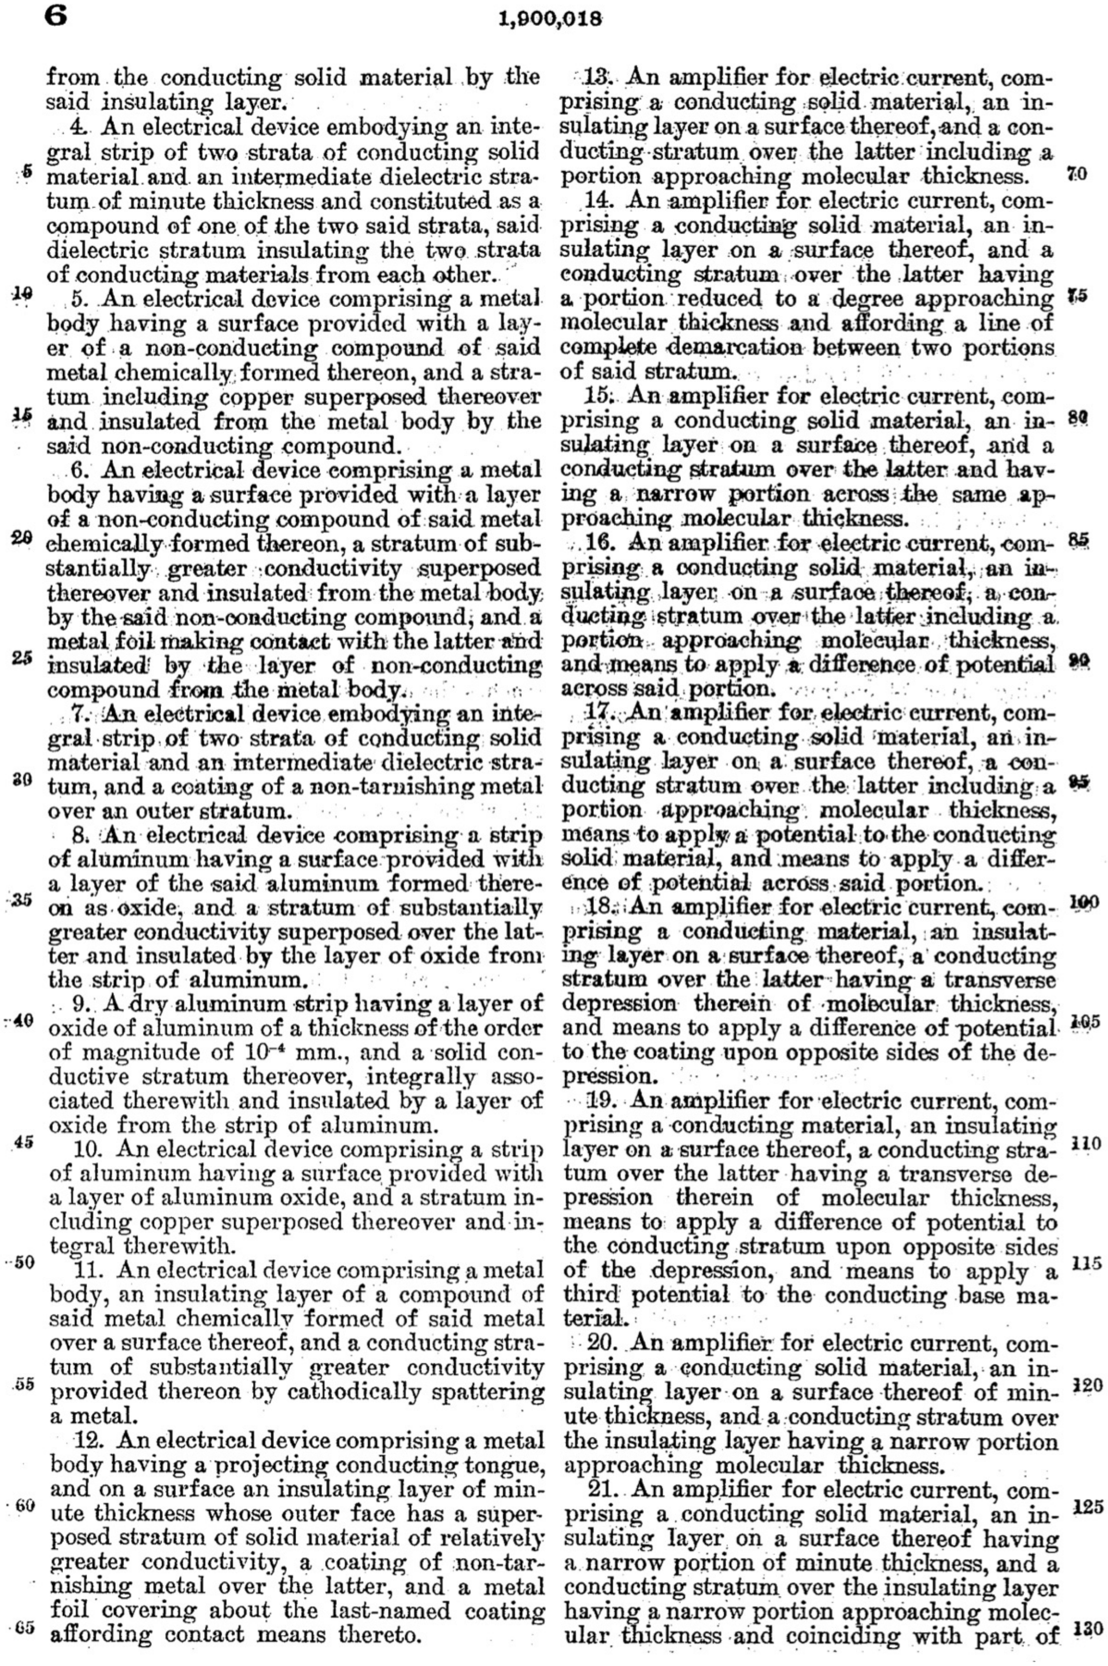
I claim:

1. An electrical device comprising a conducting solid material having on one surface an insulating layer of a thickness of the order of magnitude of 10^{-4} mm., and a superposed stratum of solid material integral therewith, of substantially greater conductivity and insulated from the conducting solid material by the said insulating layer.

2. An electrical device comprising a conducting solid material having on one surface an inorganic insulating layer of a thickness of the order of magnitude of 10^{-4} mm., and a superposed stratum of solid material integral therewith, of substantially greater conductivity and insulated from the conducting solid material by the said insulating layer.

3. An electrical device comprising a conducting solid material having on one surface an insulating layer of minute thickness and chemically formed of and on said underlying material, and a superposed stratum of solid material integral therewith, of substantially greater conductivity and insulated

Figure B.13: Julius Edgar Lilienfeld filed a number of highly detailed patent applications on field effect transistors, including U.S. Patent 1,900,018 (filed in 1928).



6 1,900,018

from the conducting solid material by the said insulating layer.

4. An electrical device embodying an integral strip of two strata of conducting solid material and an intermediate dielectric stratum of minute thickness and constituted as a compound of one of the two said strata, said dielectric stratum insulating the two strata of conducting materials from each other.

5. An electrical device comprising a metal body having a surface provided with a layer of a non-conducting compound of said metal chemically formed thereon, and a stratum including copper superposed thereover and insulated from the metal body by the said non-conducting compound.

6. An electrical device comprising a metal body having a surface provided with a layer of a non-conducting compound of said metal chemically formed thereon, a stratum of substantially greater conductivity superposed thereover and insulated from the metal body by the said non-conducting compound, and a metal foil making contact with the latter and insulated by the layer of non-conducting compound from the metal body.

7. An electrical device embodying an integral strip of two strata of conducting solid material and an intermediate dielectric stratum, and a coating of a non-tarnishing metal over an outer stratum.

8. An electrical device comprising a strip of aluminum having a surface provided with a layer of the said aluminum formed thereon as oxide, and a stratum of substantially greater conductivity superposed over the latter and insulated by the layer of oxide from the strip of aluminum.

9. A dry aluminum strip having a layer of oxide of aluminum of a thickness of the order of magnitude of 10^{-4} mm., and a solid conductive stratum thereover, integrally associated therewith and insulated by a layer of oxide from the strip of aluminum.

10. An electrical device comprising a strip of aluminum having a surface provided with a layer of aluminum oxide, and a stratum including copper superposed thereover and integral therewith.

11. An electrical device comprising a metal body, an insulating layer of a compound of said metal chemically formed of said metal over a surface thereof, and a conducting stratum of substantially greater conductivity provided thereon by cathodically spattering a metal.

12. An electrical device comprising a metal body having a projecting conducting tongue, and on a surface an insulating layer of minute thickness whose outer face has a superposed stratum of solid material of relatively greater conductivity, a coating of non-tarnishing metal over the latter, and a metal foil covering about the last-named coating affording contact means thereto.

13. An amplifier for electric current, comprising a conducting solid material, an insulating layer on a surface thereof, and a conducting stratum over the latter including a portion approaching molecular thickness.

14. An amplifier for electric current, comprising a conducting solid material, an insulating layer on a surface thereof, and a conducting stratum over the latter having a portion reduced to a degree approaching molecular thickness and affording a line of complete demarcation between two portions of said stratum.

15. An amplifier for electric current, comprising a conducting solid material, an insulating layer on a surface thereof, and a conducting stratum over the latter and having a narrow portion across the same approaching molecular thickness.

16. An amplifier for electric current, comprising a conducting solid material, an insulating layer on a surface thereof, a conducting stratum over the latter including a portion approaching molecular thickness, and means to apply a difference of potential across said portion.

17. An amplifier for electric current, comprising a conducting solid material, an insulating layer on a surface thereof, a conducting stratum over the latter including a portion approaching molecular thickness, means to apply a potential to the conducting solid material, and means to apply a difference of potential across said portion.

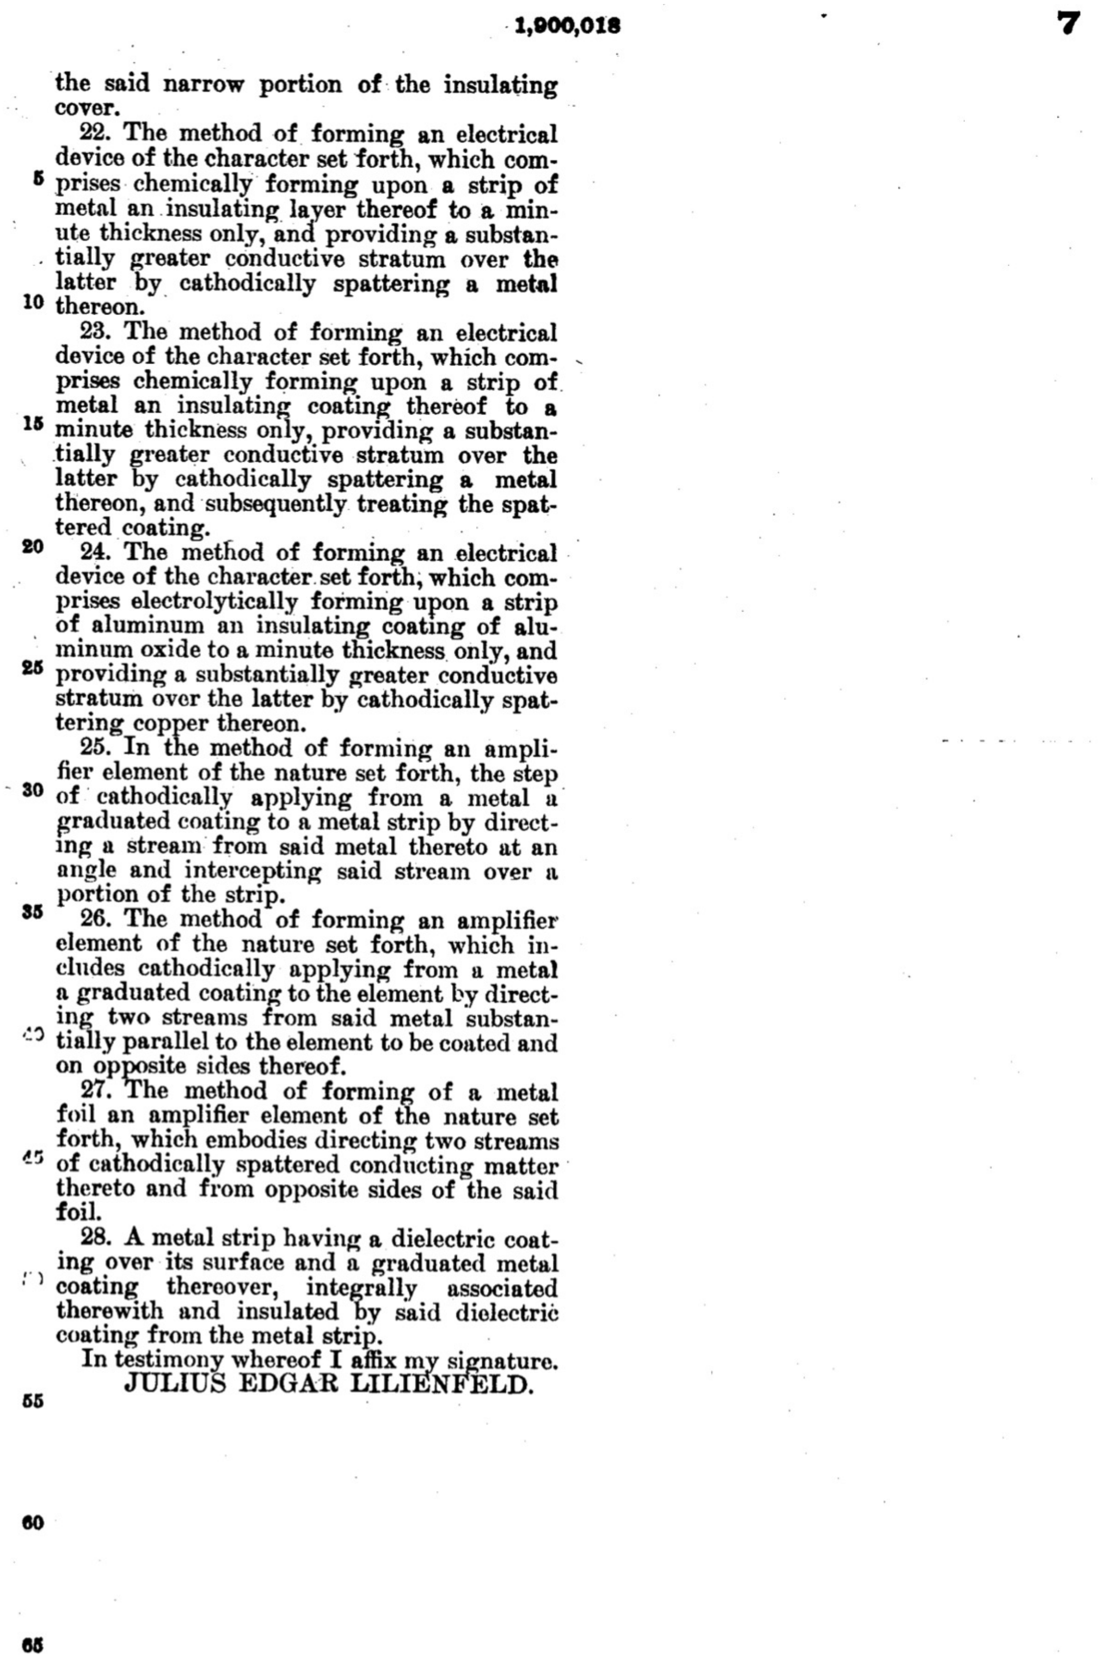
18. An amplifier for electric current, comprising a conducting material, an insulating layer on a surface thereof, a conducting stratum over the latter having a transverse depression therein of molecular thickness, and means to apply a difference of potential to the coating upon opposite sides of the depression.

19. An amplifier for electric current, comprising a conducting material, an insulating layer on a surface thereof, a conducting stratum over the latter having a transverse depression therein of molecular thickness, means to apply a difference of potential to the conducting stratum upon opposite sides of the depression, and means to apply a third potential to the conducting base material.

20. An amplifier for electric current, comprising a conducting solid material, an insulating layer on a surface thereof of minute thickness, and a conducting stratum over the insulating layer having a narrow portion approaching molecular thickness.

21. An amplifier for electric current, comprising a conducting solid material, an insulating layer on a surface thereof having a narrow portion of minute thickness, and a conducting stratum over the insulating layer having a narrow portion approaching molecular thickness and coinciding with part of

Figure B.14: Julius Edgar Lilienfeld filed a number of highly detailed patent applications on field effect transistors, including U.S. Patent 1,900,018 (filed in 1928).



1,900,018 7

the said narrow portion of the insulating cover.

22. The method of forming an electrical device of the character set forth, which comprises chemically forming upon a strip of metal an insulating layer thereof to a minute thickness only, and providing a substantially greater conductive stratum over the latter by cathodically spattering a metal thereon.

23. The method of forming an electrical device of the character set forth, which comprises chemically forming upon a strip of metal an insulating coating thereof to a minute thickness only, providing a substantially greater conductive stratum over the latter by cathodically spattering a metal thereon, and subsequently treating the spattered coating.

24. The method of forming an electrical device of the character set forth, which comprises electrolytically forming upon a strip of aluminum an insulating coating of aluminum oxide to a minute thickness only, and providing a substantially greater conductive stratum over the latter by cathodically spattering copper thereon.

25. In the method of forming an amplifier element of the nature set forth, the step of cathodically applying from a metal a graduated coating to a metal strip by directing a stream from said metal thereto at an angle and intercepting said stream over a portion of the strip.

26. The method of forming an amplifier element of the nature set forth, which includes cathodically applying from a metal a graduated coating to the element by directing two streams from said metal substantially parallel to the element to be coated and on opposite sides thereof.

27. The method of forming of a metal foil an amplifier element of the nature set forth, which embodies directing two streams of cathodically spattered conducting matter thereto and from opposite sides of the said foil.

28. A metal strip having a dielectric coating over its surface and a graduated metal coating thereover, integrally associated therewith and insulated by said dielectric coating from the metal strip.

In testimony whereof I affix my signature.

JULIUS EDGAR LILIENFELD.

UNITED STATES PATENT OFFICE

JULIUS EDGAR LILIENFELD, OF CEDARHURST, NEW YORK

AMPLIFIER FOR ELECTRIC CURRENTS

Application filed December 8, 1928. Serial No. 324,794.

The invention relates to means for controlling the flow of an electric current, more especially in relation to the amplification of the same. Various devices such as relays, thermionic and otherwise, have been utilized for this purpose; and it is the object of the present invention to afford an extremely compact, simple and durable amplifying member which will be particularly efficient for the purpose intended and which, withal, may be constructed at small expense and have extremely long life. A further object of the invention is to construct a member of this character so that the same shall have but a minimum electrostatic capacity.

More particularly, the invention consists of an amplifier comprising two outer layers and an intermediate layer in intimate contact therewith, the materials constituting the said layers being such that the two outer layers form couples, preferably asymmetric couples, with the opposite faces of the intermediate layer. The latter, moreover, is made of minute thickness, of the order of magnitude of 200$\mu\mu$, such that by reason of its porosity, or suitable treatment, the same will offer minute passages between the outer layers for the flow of electric current therebetween.

Provision is made, also, to maintain the outer layers at potentials different from each other and also different from that of the intermediate layer, which is preferably at a potential opposite to the potential of the said outer layers. The intermediate layer then constitutes a blocking layer biased to vary the resistance to the flow of electric current between the outer layers; and is also adapted to have impressed thereon a source of varying potential, such as the input current to be amplified, the output current then being taken from the outer layers with the circuit thereof including a local source of potential.

The nature of the invention, however, will best be understood when described in connection with the accompanying drawings, in which:

Fig. 1 is a fragmentary vertical section through the novel amplifier and on a greatly exaggerated scale.

Fig. 2 is an elevation, on an enlarged and exaggerated scale, illustrating a modification.

Fig. 3 is a plan view and Fig. 4 a transverse vertical section, taken on the line 4—4, Fig. 3, illustrating one means of effecting electrical contact with the respective elements of the amplifier.

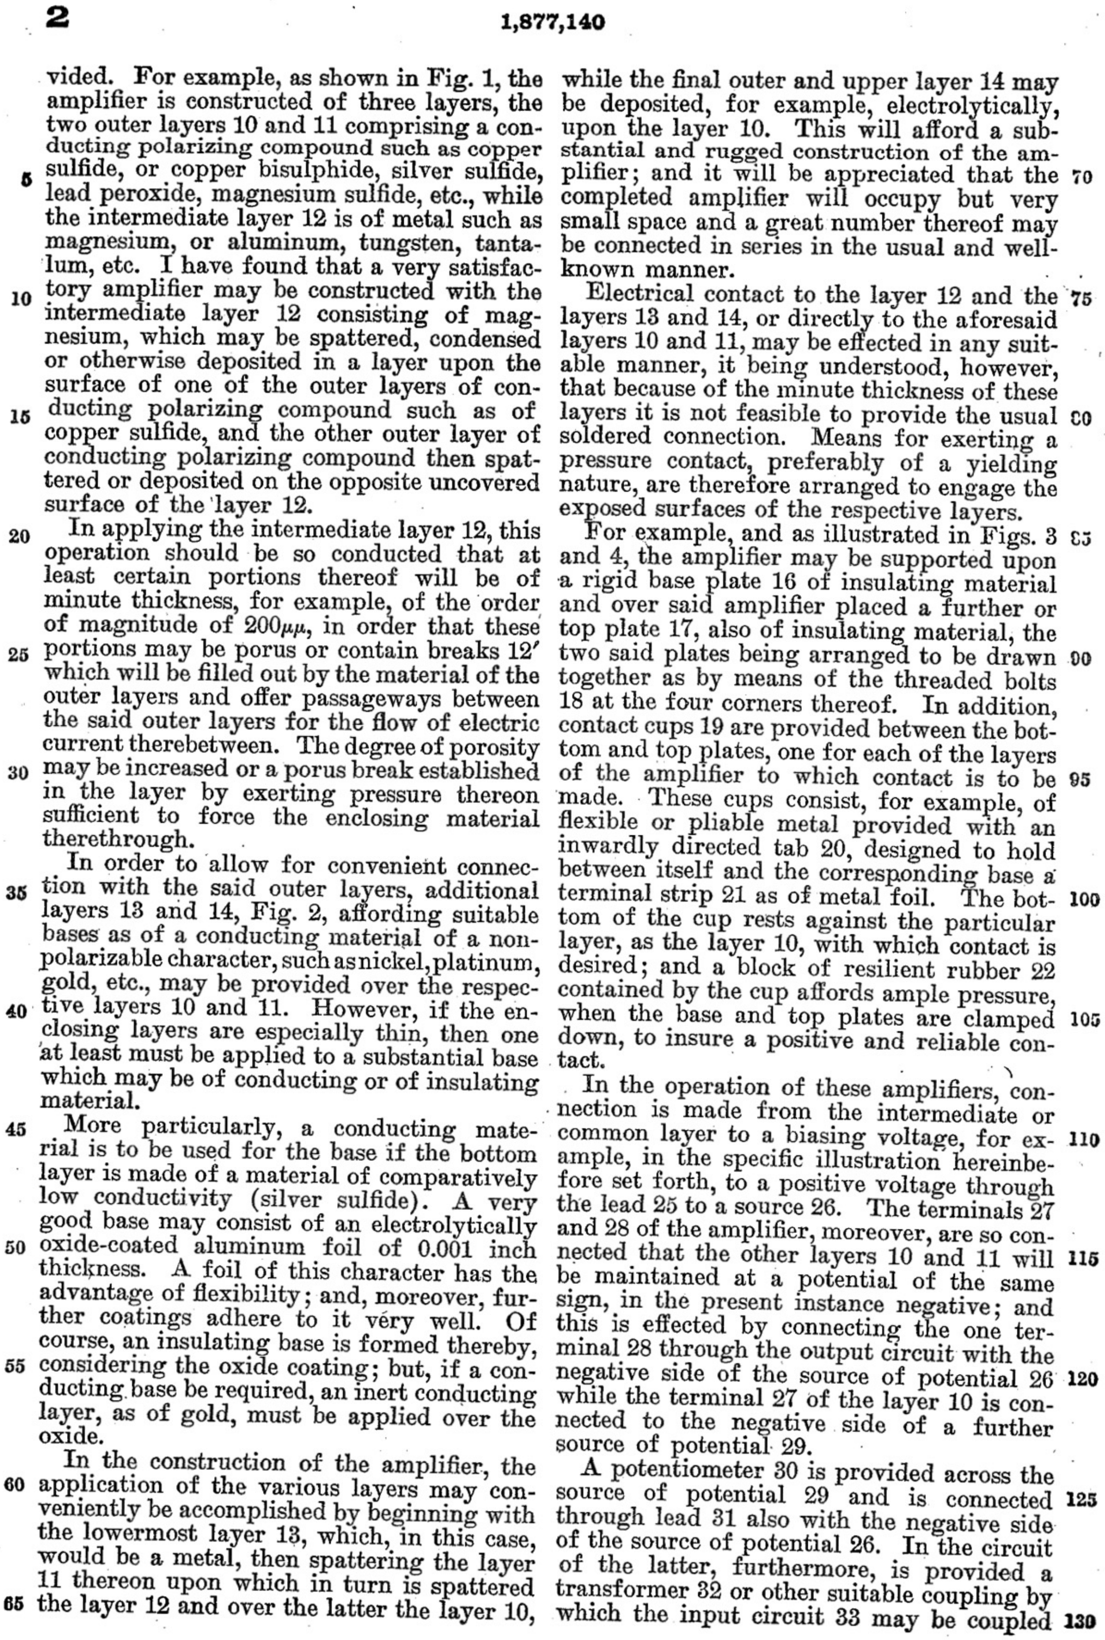
Fig. 5 is a diagrammatic view illustrating the electrical connections involved.

Fig. 6 and 7 are respectively a plan and a front elevation, on a greatly exaggerated scale, of an amplifier constructed in manner to reduce the electrostatic capacity thereof to a minimum; and Figs. 8 and 9 are similar views illustrating the construction applied to a modified form of the amplifier.

Referring to the drawings, the amplifier is indicated as constructed of a plurality of relatively thin layers of metal and compounds, the underlying principle of the amplifier being the couple—i. e., two conductors in contact with each other and of such a kind that a very high resistance is opposed to current at the transition over from one conductor to the other—and preferably the asymmetric couple. It is known that certain metals, for example magnesium, aluminum, tungsten, tantalum, etc., if brought into contact with certain compounds such as sulfides, selinides, oxides, for example, copper sulfide, silver sulfide, copper selinide, lead peroxide, etc., provide couples of a high resistance when the metal is at a positive potential and the compound negative. Asymmetric couples are also known consisting solely of compounds such as sulfides, oxides, etc. no pure metal being then involved.

In the present instance, two asymmetric couples of the aforesaid character are utilized, an element common to both being pro-

Figure B.18: Julius Edgar Lilienfeld filed a number of highly detailed patent applications on field effect transistors, including U.S. Patent 1,877,140 (filed in 1928).



2 **1,877,140**

vided. For example, as shown in Fig. 1, the amplifier is constructed of three layers, the two outer layers 10 and 11 comprising a conducting polarizing compound such as copper sulfide, or copper bisulphide, silver sulfide, lead peroxide, magnesium sulfide, etc., while the intermediate layer 12 is of metal such as magnesium, or aluminum, tungsten, tantalum, etc. I have found that a very satisfactory amplifier may be constructed with the intermediate layer 12 consisting of magnesium, which may be spattered, condensed or otherwise deposited in a layer upon the surface of one of the outer layers of conducting polarizing compound such as of copper sulfide, and the other outer layer of conducting polarizing compound then spattered or deposited on the opposite uncovered surface of the layer 12.

In applying the intermediate layer 12, this operation should be so conducted that at least certain portions thereof will be of minute thickness, for example, of the order of magnitude of $200\mu\mu$, in order that these portions may be porus or contain breaks $12'$ which will be filled out by the material of the outer layers and offer passageways between the said outer layers for the flow of electric current therebetween. The degree of porosity may be increased or a porus break established in the layer by exerting pressure thereon sufficient to force the enclosing material therethrough.

In order to allow for convenient connection with the said outer layers, additional layers 13 and 14, Fig. 2, affording suitable bases as of a conducting material of a non-polarizable character, such as nickel, platinum, gold, etc., may be provided over the respective layers 10 and 11. However, if the enclosing layers are especially thin, then one at least must be applied to a substantial base which may be of conducting or of insulating material.

More particularly, a conducting material is to be used for the base if the bottom layer is made of a material of comparatively low conductivity (silver sulfide). A very good base may consist of an electrolytically oxide-coated aluminum foil of 0.001 inch thickness. A foil of this character has the advantage of flexibility; and, moreover, further coatings adhere to it very well. Of course, an insulating base is formed thereby, considering the oxide coating; but, if a conducting base be required, an inert conducting layer, as of gold, must be applied over the oxide.

In the construction of the amplifier, the application of the various layers may conveniently be accomplished by beginning with the lowermost layer 13, which, in this case, would be a metal, then spattering the layer 11 thereon upon which in turn is spattered the layer 12 and over the latter the layer 10, while the final outer and upper layer 14 may be deposited, for example, electrolytically, upon the layer 10. This will afford a substantial and rugged construction of the amplifier; and it will be appreciated that the completed amplifier will occupy but very small space and a great number thereof may be connected in series in the usual and well-known manner.

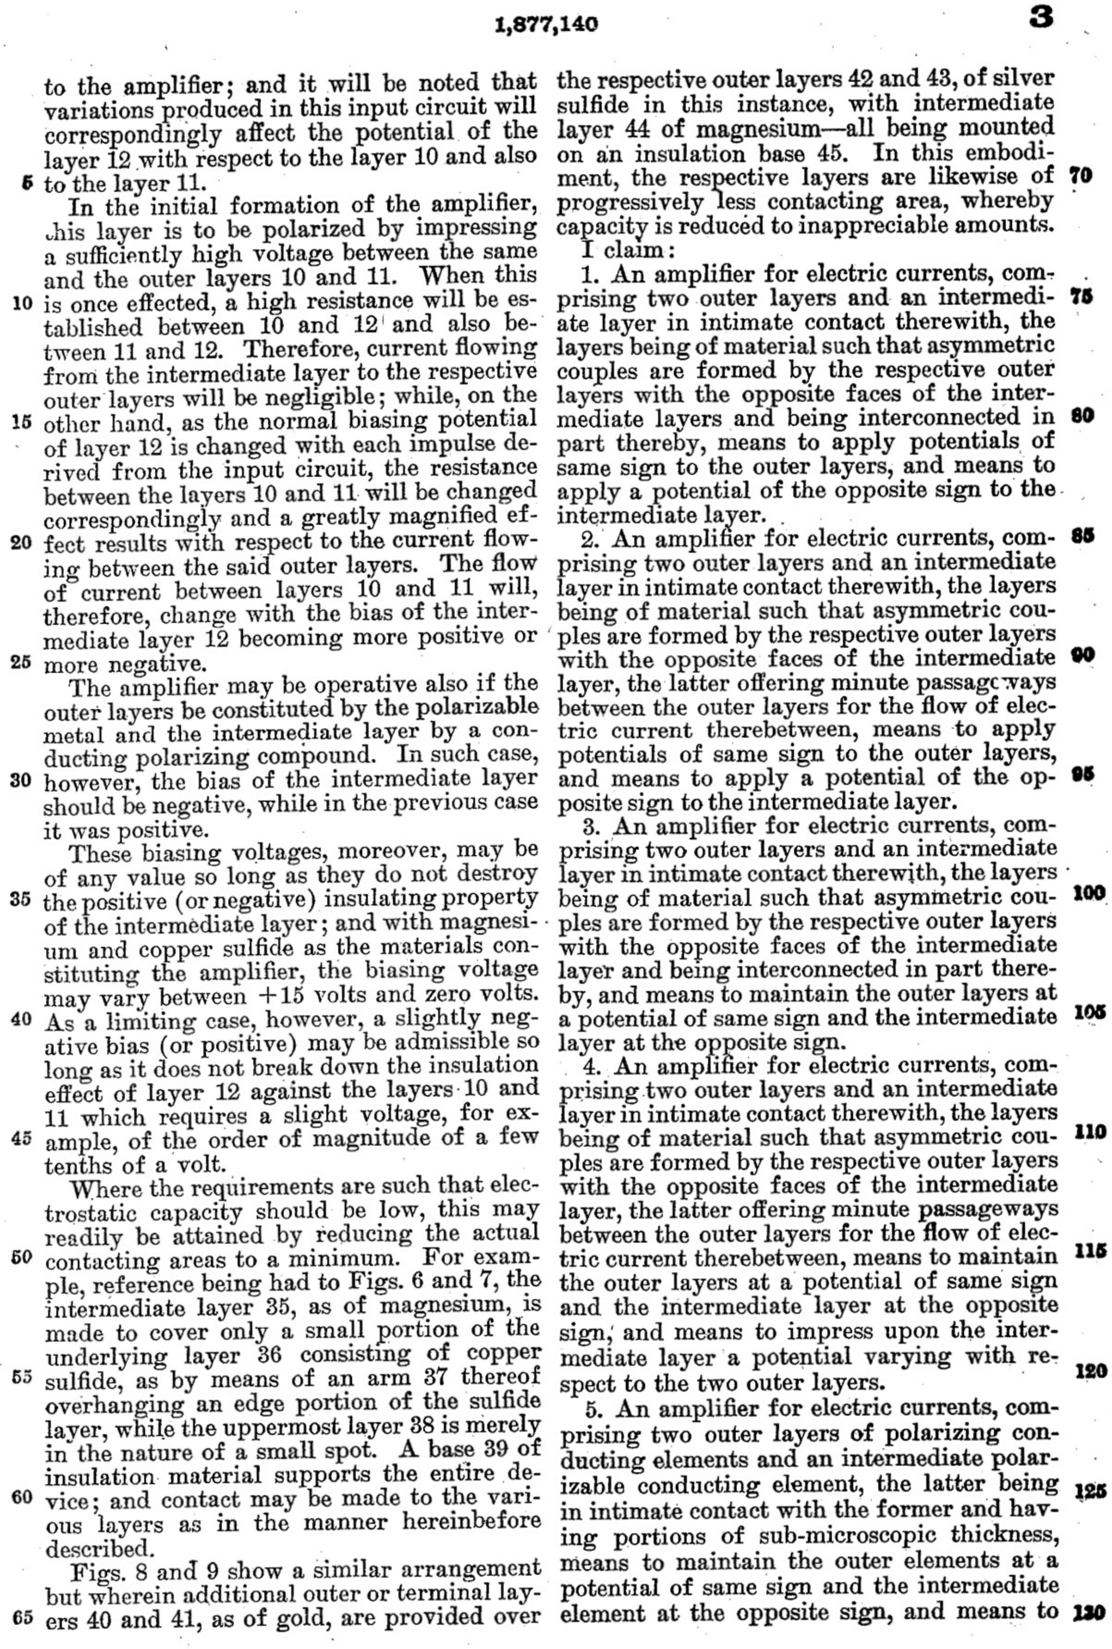
Electrical contact to the layer 12 and the layers 13 and 14, or directly to the aforesaid layers 10 and 11, may be effected in any suitable manner, it being understood, however, that because of the minute thickness of these layers it is not feasible to provide the usual soldered connection. Means for exerting a pressure contact, preferably of a yielding nature, are therefore arranged to engage the exposed surfaces of the respective layers.

For example, and as illustrated in Figs. 3 and 4, the amplifier may be supported upon a rigid base plate 16 of insulating material and over said amplifier placed a further or top plate 17, also of insulating material, the two said plates being arranged to be drawn together as by means of the threaded bolts 18 at the four corners thereof. In addition, contact cups 19 are provided between the bottom and top plates, one for each of the layers of the amplifier to which contact is to be made. These cups consist, for example, of flexible or pliable metal provided with an inwardly directed tab 20, designed to hold between itself and the corresponding base a terminal strip 21 as of metal foil. The bottom of the cup rests against the particular layer, as the layer 10, with which contact is desired; and a block of resilient rubber 22 contained by the cup affords ample pressure, when the base and top plates are clamped down, to insure a positive and reliable contact.

In the operation of these amplifiers, connection is made from the intermediate or common layer to a biasing voltage, for example, in the specific illustration hereinbefore set forth, to a positive voltage through the lead 25 to a source 26. The terminals 27 and 28 of the amplifier, moreover, are so connected that the other layers 10 and 11 will be maintained at a potential of the same sign, in the present instance negative; and this is effected by connecting the one terminal 28 through the output circuit with the negative side of the source of potential 26 while the terminal 27 of the layer 10 is connected to the negative side of a further source of potential 29.

A potentiometer 30 is provided across the source of potential 29 and is connected through lead 31 also with the negative side of the source of potential 26. In the circuit of the latter, furthermore, is provided a transformer 32 or other suitable coupling by which the input circuit 33 may be coupled

Figure B.19: Julius Edgar Lilienfeld filed a number of highly detailed patent applications on field effect transistors, including U.S. Patent 1,877,140 (filed in 1928).



1,877,140 3

to the amplifier; and it will be noted that variations produced in this input circuit will correspondingly affect the potential of the layer 12 with respect to the layer 10 and also to the layer 11.

In the initial formation of the amplifier, this layer is to be polarized by impressing a sufficiently high voltage between the same and the outer layers 10 and 11. When this is once effected, a high resistance will be established between 10 and 12 and also between 11 and 12. Therefore, current flowing from the intermediate layer to the respective outer layers will be negligible; while, on the other hand, as the normal biasing potential of layer 12 is changed with each impulse derived from the input circuit, the resistance between the layers 10 and 11 will be changed correspondingly and a greatly magnified effect results with respect to the current flowing between the said outer layers. The flow of current between layers 10 and 11 will, therefore, change with the bias of the intermediate layer 12 becoming more positive or more negative.

The amplifier may be operative also if the outer layers be constituted by the polarizable metal and the intermediate layer by a conducting polarizing compound. In such case, however, the bias of the intermediate layer should be negative, while in the previous case it was positive.

These biasing voltages, moreover, may be of any value so long as they do not destroy the positive (or negative) insulating property of the intermediate layer; and with magnesium and copper sulfide as the materials constituting the amplifier, the biasing voltage may vary between +15 volts and zero volts. As a limiting case, however, a slightly negative bias (or positive) may be admissible so long as it does not break down the insulation effect of layer 12 against the layers 10 and 11 which requires a slight voltage, for example, of the order of magnitude of a few tenths of a volt.

Where the requirements are such that electrostatic capacity should be low, this may readily be attained by reducing the actual contacting areas to a minimum. For example, reference being had to Figs. 6 and 7, the intermediate layer 35, as of magnesium, is made to cover only a small portion of the underlying layer 36 consisting of copper sulfide, as by means of an arm 37 thereof overhanging an edge portion of the sulfide layer, while the uppermost layer 38 is merely in the nature of a small spot. A base 39 of insulation material supports the entire device; and contact may be made to the various layers as in the manner hereinbefore described.

Figs. 8 and 9 show a similar arrangement but wherein additional outer or terminal layers 40 and 41, as of gold, are provided over the respective outer layers 42 and 43, of silver sulfide in this instance, with intermediate layer 44 of magnesium—all being mounted on an insulation base 45. In this embodiment, the respective layers are likewise of progressively less contacting area, whereby capacity is reduced to inappreciable amounts.

I claim:

1. An amplifier for electric currents, comprising two outer layers and an intermediate layer in intimate contact therewith, the layers being of material such that asymmetric couples are formed by the respective outer layers with the opposite faces of the intermediate layers and being interconnected in part thereby, means to apply potentials of same sign to the outer layers, and means to apply a potential of the opposite sign to the intermediate layer.

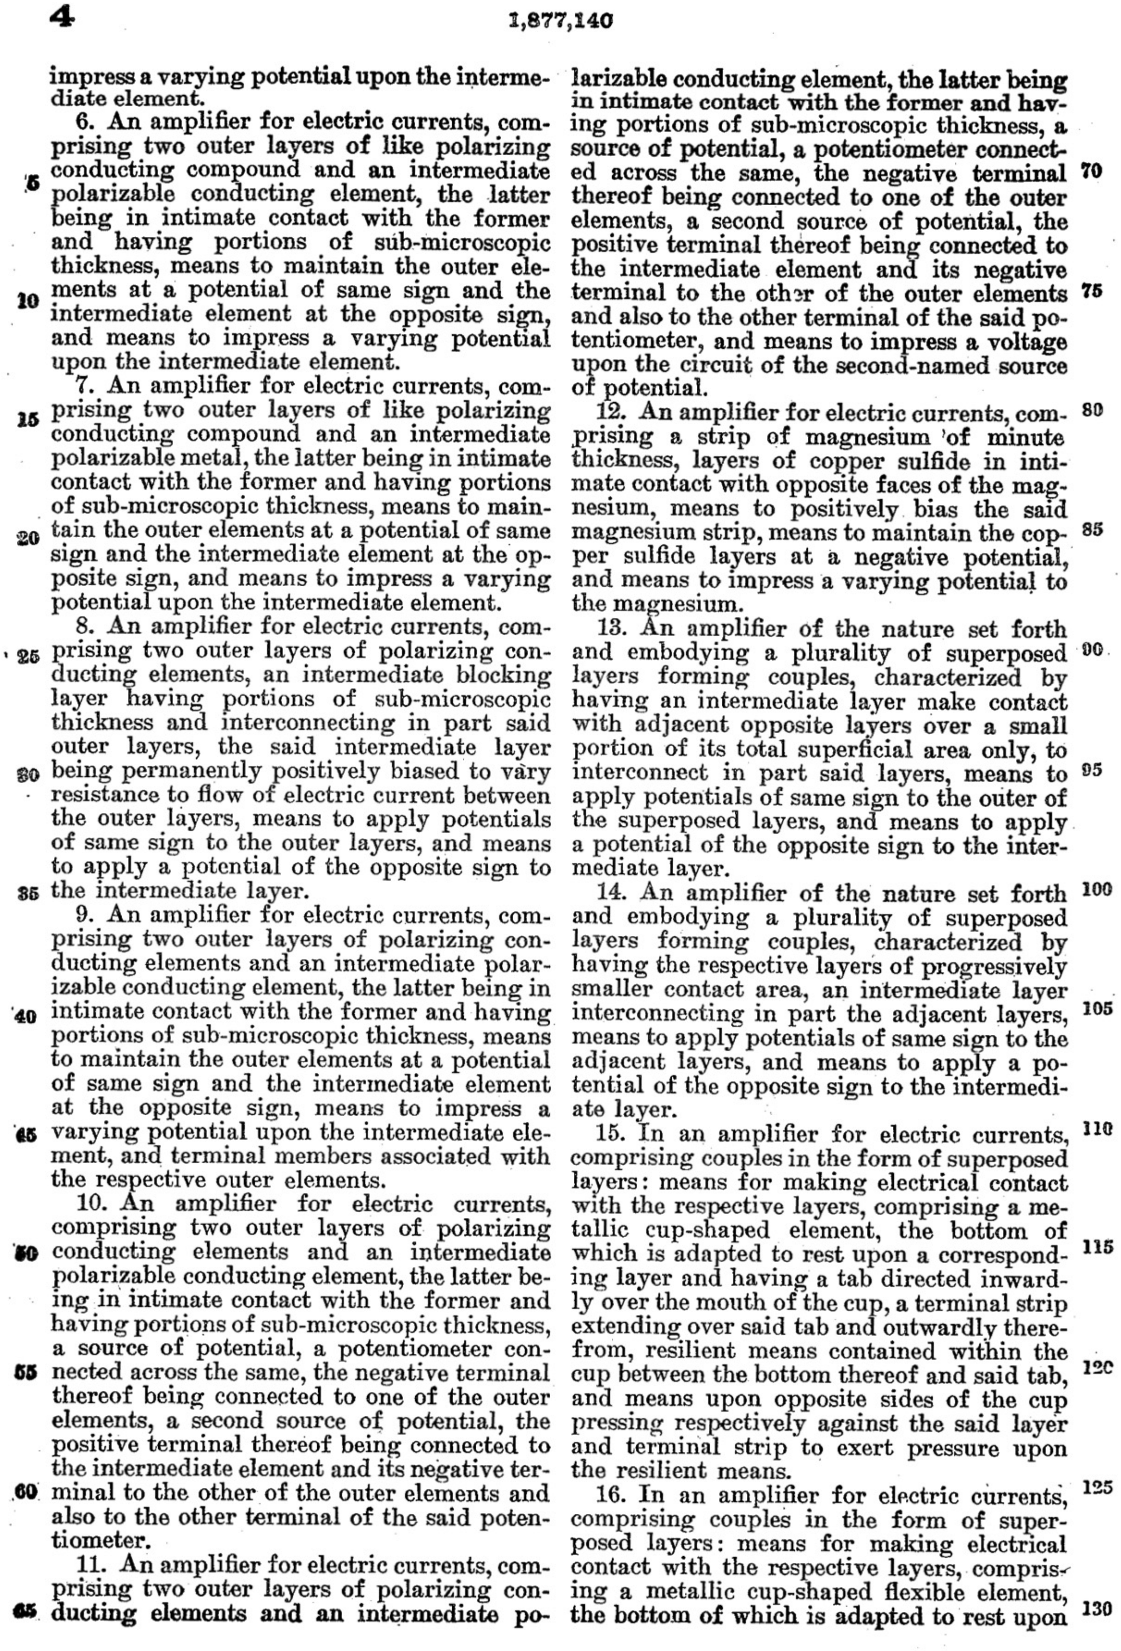
2. An amplifier for electric currents, comprising two outer layers and an intermediate layer in intimate contact therewith, the layers being of material such that asymmetric couples are formed by the respective outer layers with the opposite faces of the intermediate layer, the latter offering minute passageways between the outer layers for the flow of electric current therebetween, means to apply potentials of same sign to the outer layers, and means to apply a potential of the opposite sign to the intermediate layer.

3. An amplifier for electric currents, comprising two outer layers and an intermediate layer in intimate contact therewith, the layers being of material such that asymmetric couples are formed by the respective outer layers with the opposite faces of the intermediate layer and being interconnected in part thereby, and means to maintain the outer layers at a potential of same sign and the intermediate layer at the opposite sign.

4. An amplifier for electric currents, comprising two outer layers and an intermediate layer in intimate contact therewith, the layers being of material such that asymmetric couples are formed by the respective outer layers with the opposite faces of the intermediate layer, the latter offering minute passageways between the outer layers for the flow of electric current therebetween, means to maintain the outer layers at a potential of same sign and the intermediate layer at the opposite sign, and means to impress upon the intermediate layer a potential varying with respect to the two outer layers.

5. An amplifier for electric currents, comprising two outer layers of polarizing conducting elements and an intermediate polarizable conducting element, the latter being in intimate contact with the former and having portions of sub-microscopic thickness, means to maintain the outer elements at a potential of same sign and the intermediate element at the opposite sign, and means to

Figure B.20: Julius Edgar Lilienfeld filed a number of highly detailed patent applications on field effect transistors, including U.S. Patent 1,877,140 (filed in 1928).



4

1,877,140

impress a varying potential upon the intermediate element.

6. An amplifier for electric currents, comprising two outer layers of like polarizing conducting compound and an intermediate polarizable conducting element, the latter being in intimate contact with the former and having portions of sub-microscopic thickness, means to maintain the outer elements at a potential of same sign and the intermediate element at the opposite sign, and means to impress a varying potential upon the intermediate element.

7. An amplifier for electric currents, comprising two outer layers of like polarizing conducting compound and an intermediate polarizable metal, the latter being in intimate contact with the former and having portions of sub-microscopic thickness, means to maintain the outer elements at a potential of same sign and the intermediate element at the opposite sign, and means to impress a varying potential upon the intermediate element.

8. An amplifier for electric currents, comprising two outer layers of polarizing conducting elements, an intermediate blocking layer having portions of sub-microscopic thickness and interconnecting in part said outer layers, the said intermediate layer being permanently positively biased to vary resistance to flow of electric current between the outer layers, means to apply potentials of same sign to the outer layers, and means to apply a potential of the opposite sign to the intermediate layer.

9. An amplifier for electric currents, comprising two outer layers of polarizing conducting elements and an intermediate polarizable conducting element, the latter being in intimate contact with the former and having portions of sub-microscopic thickness, means to maintain the outer elements at a potential of same sign and the intermediate element at the opposite sign, means to impress a varying potential upon the intermediate element, and terminal members associated with the respective outer elements.

10. An amplifier for electric currents, comprising two outer layers of polarizing conducting elements and an intermediate polarizable conducting element, the latter being in intimate contact with the former and having portions of sub-microscopic thickness, a source of potential, a potentiometer connected across the same, the negative terminal thereof being connected to one of the outer elements, a second source of potential, the positive terminal thereof being connected to the intermediate element and its negative terminal to the other of the outer elements and also to the other terminal of the said potentiometer.

11. An amplifier for electric currents, comprising two outer layers of polarizing conducting elements and an intermediate polarizable conducting element, the latter being in intimate contact with the former and having portions of sub-microscopic thickness, a source of potential, a potentiometer connected across the same, the negative terminal thereof being connected to one of the outer elements, a second source of potential, the positive terminal thereof being connected to the intermediate element and its negative terminal to the other of the outer elements and also to the other terminal of the said potentiometer, and means to impress a voltage upon the circuit of the second-named source of potential.

12. An amplifier for electric currents, comprising a strip of magnesium of minute thickness, layers of copper sulfide in intimate contact with opposite faces of the magnesium, means to positively bias the said magnesium strip, means to maintain the copper sulfide layers at a negative potential, and means to impress a varying potential to the magnesium.

13. An amplifier of the nature set forth and embodying a plurality of superposed layers forming couples, characterized by having an intermediate layer make contact with adjacent opposite layers over a small portion of its total superficial area only, to interconnect in part said layers, means to apply potentials of same sign to the outer of the superposed layers, and means to apply a potential of the opposite sign to the intermediate layer.

14. An amplifier of the nature set forth and embodying a plurality of superposed layers forming couples, characterized by having the respective layers of progressively smaller contact area, an intermediate layer interconnecting in part the adjacent layers, means to apply potentials of same sign to the adjacent layers, and means to apply a potential of the opposite sign to the intermediate layer.

15. In an amplifier for electric currents, comprising couples in the form of superposed layers: means for making electrical contact with the respective layers, comprising a metallic cup-shaped element, the bottom of which is adapted to rest upon a corresponding layer and having a tab directed inwardly over the mouth of the cup, a terminal strip extending over said tab and outwardly therefrom, resilient means contained within the cup between the bottom thereof and said tab, and means upon opposite sides of the cup pressing respectively against the said layer and terminal strip to exert pressure upon the resilient means.

16. In an amplifier for electric currents, comprising couples in the form of superposed layers: means for making electrical contact with the respective layers, comprising a metallic cup-shaped flexible element, the bottom of which is adapted to rest upon

HAUPTPATENT

Dr. Oskar HEIL, Berlin-Grunewald (Deutschland).

Verfahren zum Steuern oder Verstärken elektrischer Ströme.

Die vorliegende Erfindung betrifft ein Verfahren und eine Vorrichtung zum Steuern oder Verstärken elektrischer Ströme.

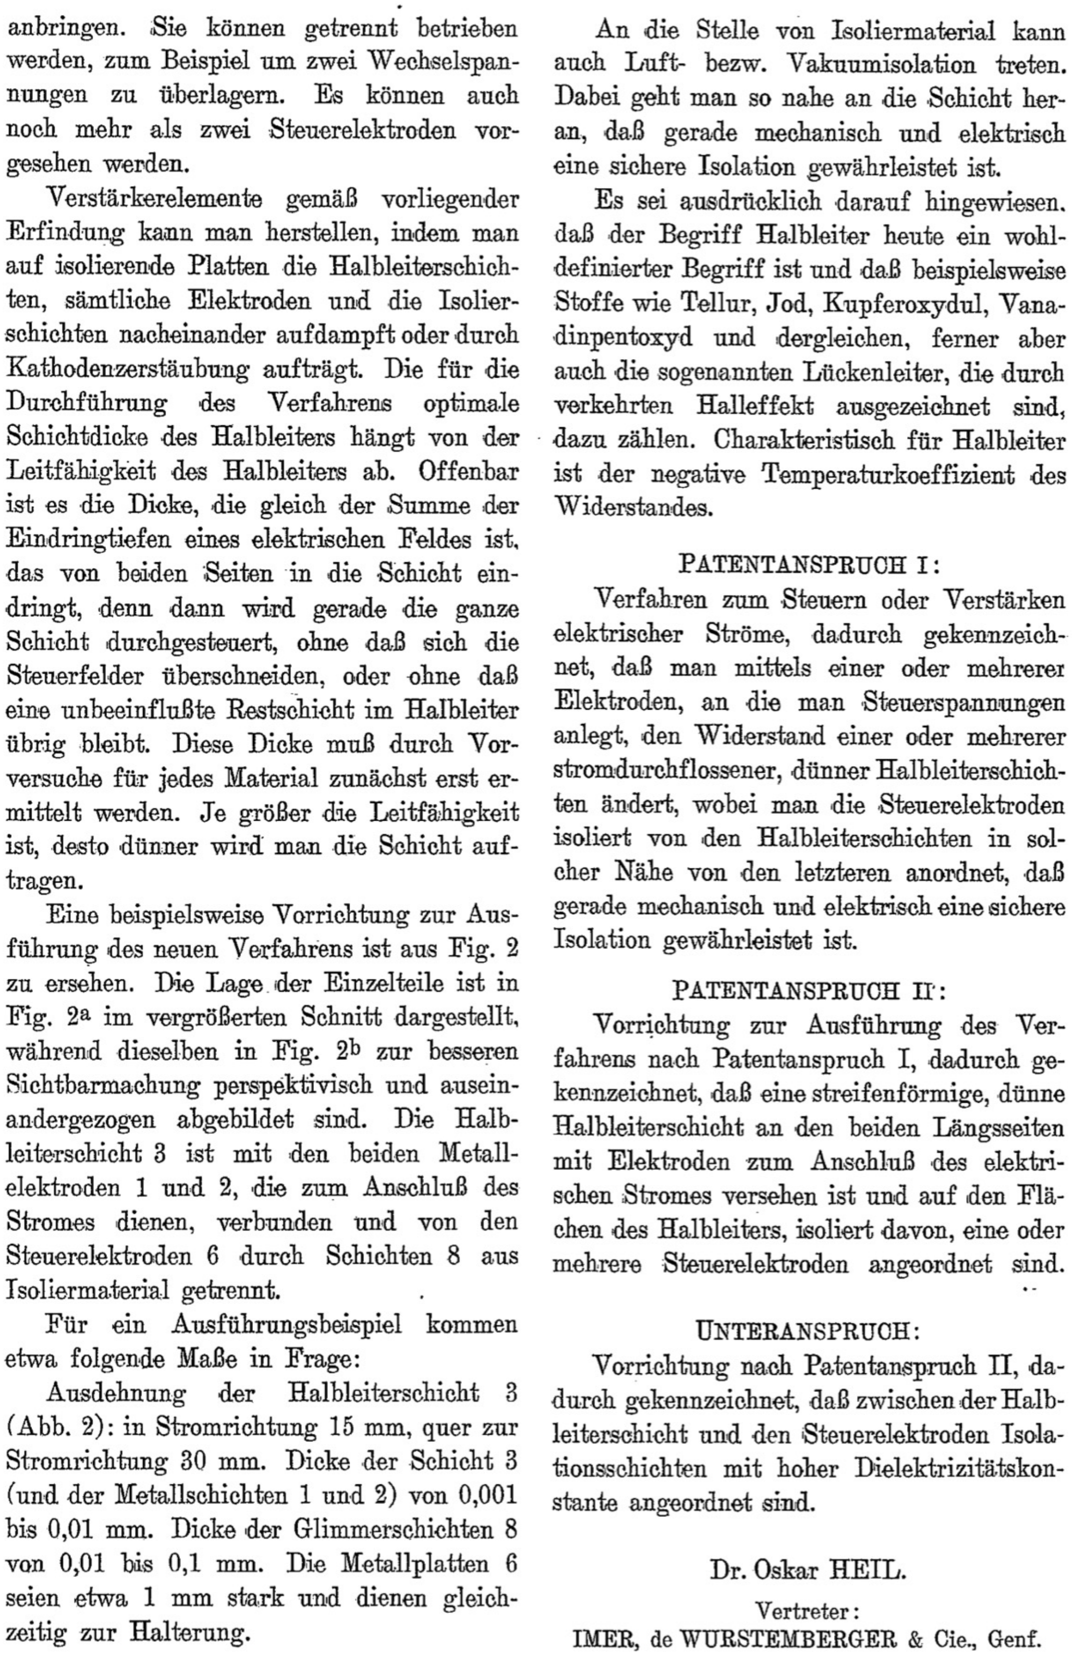
Während man bisher zu diesem Zweck fast ausschließlich Elektronenröhren verwendet hat, beruht das erfindungsgemäß beanspruchte Verfahren auf einem ganz neuen Effekt, der zum ersten Mal beobachtet wurde.

Es wurde festgestellt, daß dünne Schichten von Halbleitern ihren Widerstand für den elektrischen Strom in weiten Grenzen ändern, wenn man diese Schichten als Elektroden von Kondensatoren ausbildet und die Elektroden auf verschiedene Spannung auflädt.

Zur näheren Erläuterung diene die schematische beispielsweise Darstellung in Fig. 1. Zwischen den Metallelektroden 1 und 2 befindet sich die dünne Schicht des Halbleiters 3. Die Batterie 4 schickt einen Strom durch die dünne Halbleiterschicht, der mittels Amperemeter 5 gemessen wird. Lädt man nun die Elektrode 6 positiv oder negativ gegenüber der Schicht 3 auf, so ändert sich der elektrische Widerstand dieser Schicht und damit auch die am Amperemeter 5 gemessene Stromstärke. Es ist also möglich, durch Anlegen einer irgendwie geformten Wechselspannung an die Klemmen 7 den Strom in 5 zu steuern. Mit solchen Anordnungen lassen sich in ähnlicher Weise wie mit Elektronenröhren Verstärker bauen. Es ist vorteilhaft, den Abstand zwischen der Elektrode 6 und dem Halbleiter 3 möglichst gering zu machen, etwa durch Verwendung einer dünnen Isolierschicht von weniger als $^1/_{100}$ mm Dicke zwischen beiden. Zweckmäßigerweise findet dabei ein Isoliermaterial von hoher Dielektrizitätskonstante Anwendung (mit einem Zahlenwert von 10 oder darüber).

Statt eine Steuerelektrode 6 kann man auch zwei Steuerelektroden 6 zu beiden Seiten der Schicht 3 anordnen; statt dessen können solche auch nur auf einer Seite angebracht werden. Man kann sie in diesem Falle nebeneinander oder hintereinander, bezogen auf die Stromrichtung im Halbleiter,

Figure B.23: Oskar Heil filed patent applications on field effect transistors in Germany and other countries in 1934.



anbringen. Sie können getrennt betrieben werden, zum Beispiel um zwei Wechselspannungen zu überlagern. Es können auch noch mehr als zwei Steuerelektroden vorgesehen werden.

Verstärkerelemente gemäß vorliegender Erfindung kann man herstellen, indem man auf isolierende Platten die Halbleiterschichten, sämtliche Elektroden und die Isolierschichten nacheinander aufdampft oder durch Kathodenzerstäubung aufträgt. Die für die Durchführung des Verfahrens optimale Schichtdicke des Halbleiters hängt von der Leitfähigkeit des Halbleiters ab. Offenbar ist es die Dicke, die gleich der Summe der Eindringtiefen eines elektrischen Feldes ist, das von beiden Seiten in die Schicht eindringt, denn dann wird gerade die ganze Schicht durchgesteuert, ohne daß sich die Steuerfelder überschneiden, oder ohne daß eine unbeeinflußte Restschicht im Halbleiter übrig bleibt. Diese Dicke muß durch Vorversuche für jedes Material zunächst erst ermittelt werden. Je größer die Leitfähigkeit ist, desto dünner wird man die Schicht auftragen.

Eine beispielsweise Vorrichtung zur Ausführung des neuen Verfahrens ist aus Fig. 2 zu ersehen. Die Lage der Einzelteile ist in Fig. 2^a im vergrößerten Schnitt dargestellt, während dieselben in Fig. 2^b zur besseren Sichtbarmachung perspektivisch und auseinandergezogen abgebildet sind. Die Halbleiterschicht 3 ist mit den beiden Metallelektroden 1 und 2, die zum Anschluß des Stromes dienen, verbunden und von den Steuerelektroden 6 durch Schichten 8 aus Isoliermaterial getrennt.

Für ein Ausführungsbeispiel kommen etwa folgende Maße in Frage:

Ausdehnung der Halbleiterschicht 3 (Abb. 2): in Stromrichtung 15 mm, quer zur Stromrichtung 30 mm. Dicke der Schicht 3 (und der Metallschichten 1 und 2) von 0,001 bis 0,01 mm. Dicke der Glimmerschichten 8 von 0,01 bis 0,1 mm. Die Metallplatten 6 seien etwa 1 mm stark und dienen gleichzeitig zur Halterung.

An die Stelle von Isoliermaterial kann auch Luft- bezw. Vakuumisolation treten. Dabei geht man so nahe an die Schicht heran, daß gerade mechanisch und elektrisch eine sichere Isolation gewährleistet ist.

Es sei ausdrücklich darauf hingewiesen, daß der Begriff Halbleiter heute ein wohldefinierter Begriff ist und daß beispielsweise Stoffe wie Tellur, Jod, Kupferoxydul, Vanadinpentoxyd und dergleichen, ferner aber auch die sogenannten Lückenleiter, die durch verkehrten Halleffekt ausgezeichnet sind, dazu zählen. Charakteristisch für Halbleiter ist der negative Temperaturkoeffizient des Widerstandes.

PATENTANSPRUCH I:

Verfahren zum Steuern oder Verstärken elektrischer Ströme, dadurch gekennzeichnet, daß man mittels einer oder mehrerer Elektroden, an die man Steuerspannungen anlegt, den Widerstand einer oder mehrerer stromdurchflossener, dünner Halbleiterschichten ändert, wobei man die Steuerelektroden isoliert von den Halbleiterschichten in solcher Nähe von den letzteren anordnet, daß gerade mechanisch und elektrisch eine sichere Isolation gewährleistet ist.

PATENTANSPRUCH II:

Vorrichtung zur Ausführung des Verfahrens nach Patentanspruch I, dadurch gekennzeichnet, daß eine streifenförmige, dünne Halbleiterschicht an den beiden Längsseiten mit Elektroden zum Anschluß des elektrischen Stromes versehen ist und auf den Flächen des Halbleiters, isoliert davon, eine oder mehrere Steuerelektroden angeordnet sind.

UNTERANSPRUCH:

Vorrichtung nach Patentanspruch II, dadurch gekennzeichnet, daß zwischen der Halbleiterschicht und den Steuerelektroden Isolationsschichten mit hoher Dielektrizitätskonstante angeordnet sind.

COMPLETE SPECIFICATION

Improvements in or relating to Electrical Amplifiers and other Control Arrangements and Devices

I, Oskar Heil, German citizen, of 21 Jagowstrasse, Berlin-Grunewald, Germany, do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:—

This invention relates to electrical amplifiers and the like and provides novel apparatus adapted to effect alternating current amplification and to perform other functions e.g. general control functions such as have usually been performed hitherto by thermionic valves. In general terms the present invention—which, as will be seen later, embodies a principle which is believed to be new and is based upon a discovery believed to be new—may be stated to provide a substitute for thermionic valves.

The discovery upon which this invention is based is that if a semi-conductor be arranged as to form part of a condenser which is subjected to a varying voltage charge the resistance thereof will vary as a function of said varying voltage and according to this invention this phenomenon or effect is utilised for amplifying or other control purposes.

It has been discovered that a thin layer of semi-conductor will fluctuate within wide limits in its resistance to an electric current if the said layer be arranged to act as an electrode of a condenser which is charged to a varying voltage.

The invention is illustrated in and further explained in connection with the accompanying diagrammatic drawings.

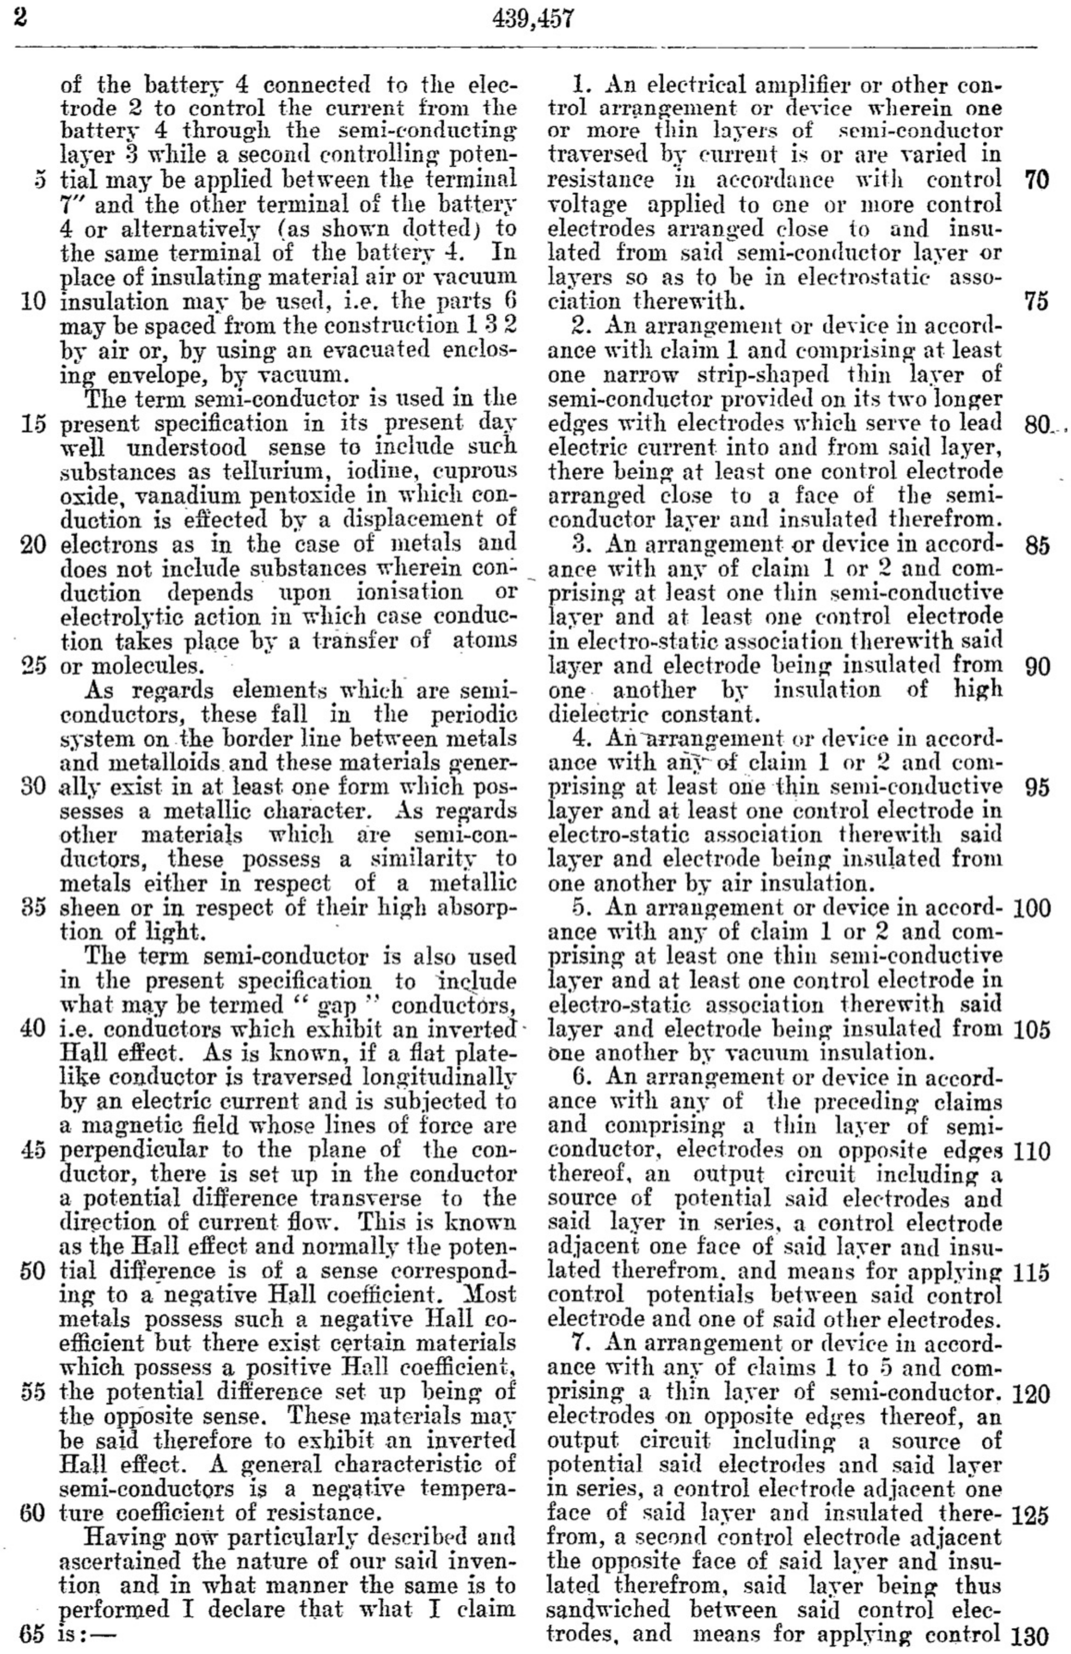
Referring to fig. 1 which serves to illustrate the essential principle of the invention 1 and 2 are metal electrodes between which is a thin layer 3 of a semiconductor. A battery 4 sends a current through the thin layer of semi-conductor and this current is measured by the ammeter 5. If, now, an electrode 6 in electro-static association with the layer 3 is charged positively or negatively in relation to the said layer 3, the electrical resistance of this layer is found to vary and the current strength as measured by the ammeter 5 also to vary. Thus it is possible by the application of an alternating voltage of any wave form to the terminals 7 to produce a corresponding variation in the current through 5. This principle may be utilised to provide amplifiers which act in a way analogous to thermionic valve amplifiers. It is advantageous to make the distance between the electrode 6 and the semiconductor 3 as small as possible, e.g. by providing a thin layer of insulation—preferably one having a high dielectric constant—between them.

Control electrodes playing a function like that of electrode 6 of fig. 1 can be provided on both sides of the layer 3. Again a plurality of control electrodes may be arranged next each other or one behind the other on one or both sides of the layer 3 and these electrodes may be operated separately, e.g. for the purpose of effecting simultaneous control by a plurality of alternating voltages.

Amplifier devices in accordance with the present invention can be made in various ways a preferred way being by applying the layers of semi-conductor, all the required electrodes and the insulating layers in succession to insulating plates the metal members being applied either by vaporizing metal or by depositing metal by cathode dispersion. The best thickness of semi-conductor layer to be used in any case depends on the conductivity of the semi-conductor employed and should be first ascertained by experiment for each semi-conductor material. In general, the greater the conductivity of the semi-conductor the more thin must be the layer thereof for best results.

One arrangement in accordance with this invention is shown in figure 2, the separate points embodied in figure 2 being shown assembled at *a* and enlarged and in exploded perspective view at *b*. In figure 2, 3 is a layer of semi-conductor which is connected to two metallic electrodes 1 and 2 via which the current to be controlled is passed through the layer 3. 6 are the control electrodes and these are separated from the construction 1 3 2 by layers 8 of insulating material. One controlling potential may be applied between the terminal 7′ and the terminal

Figure B.26: Oskar Heil filed patent applications on field effect transistors in Germany and other countries in 1934.



of the battery 4 connected to the electrode 2 to control the current from the battery 4 through the semi-conducting layer 3 while a second controlling potential may be applied between the terminal 7″ and the other terminal of the battery 4 or alternatively (as shown dotted) to the same terminal of the battery 4. In place of insulating material air or vacuum insulation may be used, i.e. the parts 6 may be spaced from the construction 1 3 2 by air or, by using an evacuated enclosing envelope, by vacuum.

The term semi-conductor is used in the present specification in its present day well understood sense to include such substances as tellurium, iodine, cuprous oxide, vanadium pentoxide in which conduction is effected by a displacement of electrons as in the case of metals and does not include substances wherein conduction depends upon ionisation or electrolytic action in which case conduction takes place by a transfer of atoms or molecules.

As regards elements which are semi-conductors, these fall in the periodic system on the border line between metals and metalloids and these materials generally exist in at least one form which possesses a metallic character. As regards other materials which are semi-conductors, these possess a similarity to metals either in respect of a metallic sheen or in respect of their high absorption of light.

The term semi-conductor is also used in the present specification to include what may be termed " gap " conductors, i.e. conductors which exhibit an inverted Hall effect. As is known, if a flat plate-like conductor is traversed longitudinally by an electric current and is subjected to a magnetic field whose lines of force are perpendicular to the plane of the conductor, there is set up in the conductor a potential difference transverse to the direction of current flow. This is known as the Hall effect and normally the potential difference is of a sense corresponding to a negative Hall coefficient. Most metals possess such a negative Hall coefficient but there exist certain materials which possess a positive Hall coefficient, the potential difference set up being of the opposite sense. These materials may be said therefore to exhibit an inverted Hall effect. A general characteristic of semi-conductors is a negative temperature coefficient of resistance.

Having now particularly described and ascertained the nature of our said invention and in what manner the same is to performed I declare that what I claim is:—

1. An electrical amplifier or other control arrangement or device wherein one or more thin layers of semi-conductor traversed by current is or are varied in resistance in accordance with control voltage applied to one or more control electrodes arranged close to and insulated from said semi-conductor layer or layers so as to be in electrostatic association therewith.

2. An arrangement or device in accordance with claim 1 and comprising at least one narrow strip-shaped thin layer of semi-conductor provided on its two longer edges with electrodes which serve to lead electric current into and from said layer, there being at least one control electrode arranged close to a face of the semi-conductor layer and insulated therefrom.

3. An arrangement or device in accordance with any of claim 1 or 2 and comprising at least one thin semi-conductive layer and at least one control electrode in electro-static association therewith said layer and electrode being insulated from one another by insulation of high dielectric constant.

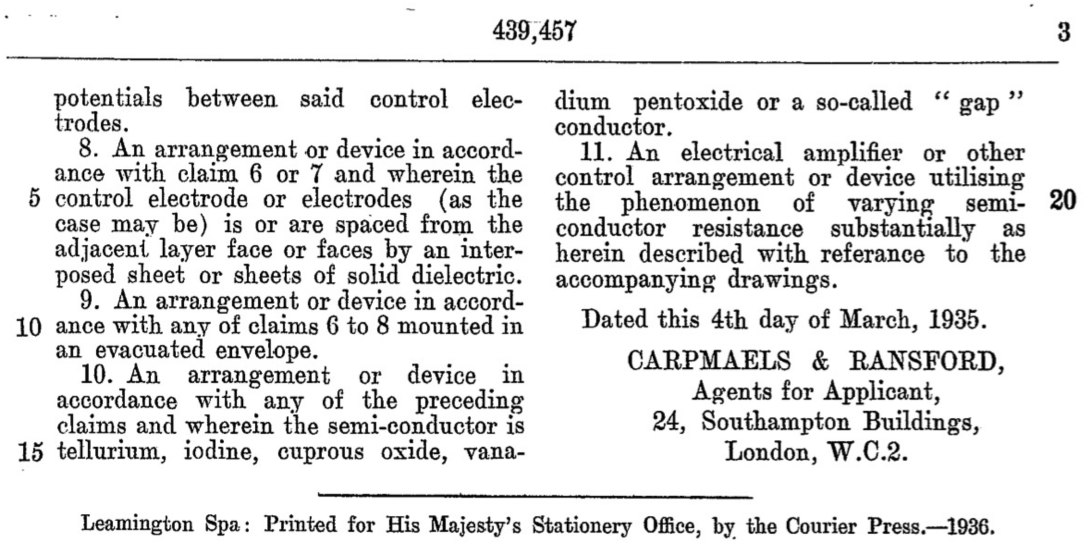
4. An arrangement or device in accordance with any of claim 1 or 2 and comprising at least one thin semi-conductive layer and at least one control electrode in electro-static association therewith said layer and electrode being insulated from one another by air insulation.

5. An arrangement or device in accordance with any of claim 1 or 2 and comprising at least one thin semi-conductive layer and at least one control electrode in electro-static association therewith said layer and electrode being insulated from one another by vacuum insulation.

6. An arrangement or device in accordance with any of the preceding claims and comprising a thin layer of semi-conductor, electrodes on opposite edges thereof, an output circuit including a source of potential said electrodes and said layer in series, a control electrode adjacent one face of said layer and insulated therefrom. and means for applying control potentials between said control electrode and one of said other electrodes.

7. An arrangement or device in accordance with any of claims 1 to 5 and comprising a thin layer of semi-conductor. electrodes on opposite edges thereof, an output circuit including a source of potential said electrodes and said layer in series, a control electrode adjacent one face of said layer and insulated therefrom, a second control electrode adjacent the opposite face of said layer and insulated therefrom, said layer being thus sandwiched between said control electrodes, and means for applying control

Figure B.27: Oskar Heil filed patent applications on field effect transistors in Germany and other countries in 1934.



potentials between said control electrodes.

8. An arrangement or device in accordance with claim 6 or 7 and wherein the control electrode or electrodes (as the case may be) is or are spaced from the adjacent layer face or faces by an interposed sheet or sheets of solid dielectric.

9. An arrangement or device in accordance with any of claims 6 to 8 mounted in an evacuated envelope.

10. An arrangement or device in accordance with any of the preceding claims and wherein the semi-conductor is tellurium, iodine, cuprous oxide, vanadium pentoxide or a so-called "gap" conductor.

11. An electrical amplifier or other control arrangement or device utilising the phenomenon of varying semi-conductor resistance substantially as herein described with referance to the accompanying drawings.

Dated this 4th day of March, 1935.

3. Gilles Holst (Dutch, 1886–1968) and Willem Christiaan van Geel (Dutch, 1895–1967) filed a patent application on transistors in 1935 [Van Delft 2014]:

> Gilles Holst and Willem Christiaan van Geel. Filed in Germany in 1935 and subsequently in other countries. U.S. patent 2,173,904. Electrode System of Unsymmetrical Conductivity.

See pp. 2687–2689.

Holst was the research director at the Philips Eindhoven laboratory, and van Geel was an expert there on metal and semiconductor materials. Both were nominated for the Nobel Prize in Physics but never won.[1]

Holst was also one of the inventors of the sodium vapor lamp in 1932 (p. 971).

Philips Eindhoven was closely tied to the rest of the predominantly German-speaking research world from the late nineteenth century through World War II, including work on electronics, communications, and directed energy beams.[2]

To what extent was the work by Holst and van Geel based on the earlier patents of Julius Lilienfeld and Oscar Heil?

How much did they interact with other groups in the greater German-speaking world that were trying to develop transistors in the 1930s and early 1940s?

How far did the transistor-related work of Holst and van Geel get by 1945?

Did their work influence postwar projects at Bell Laboratories?

Much more archival research is needed.]

2,173,904

ELECTRODE SYSTEM OF UNSYMMETRICAL CONDUCTIVITY

Gilles Holst and Willem Christiaan van Geel, Eindhoven, Netherlands, assignors to N. V. Philips' Gloeilampenfabrieken, Eindhoven, Netherlands

Application March 4, 1936, Serial No. 67,052
In Germany March 9, 1935

3 Claims. (Cl. 179—171)

The invention relates to an electrode system of unsymmetrical conductivity formed by two layers of different emitting capacity which are separated from one another by a layer of insulating material.

It is known already that if cuprous oxide rectifiers form the starting point, a three-electrode system may be produced by providing in the semi-conductive oxide layer a grid to which an auxiliary voltage is applied in order to act upon the electron current flowing from the copper electrode to the semi-conductor. Experiments have shown, however, that a detector thus produced does not function satisfactorily.

Furthermore, it has previously been proposed to form a detector as a dry rectifier in which the electron current between the metallic electrode and the semi-conductor is acted upon by the field variation of a magnetic circuit of which the rectifier forms a part. This form of construction has the drawback that it takes up much room and cannot be operated in a simple manner.

The invention has for its object to provide a detector or amplifier capable of taking the place of the present valves with thermal emission which are complicated and expensive in initial cost as well as in operation, for example, due to the current consumption for heating the cathode.

According to the invention, an electrode system of unsymmetrical conductivity is formed by two layers of different emitting capacity which are separated from one another by a layer of insulating material, and embedded in the insulating intermediate layer is a grid provided with a supply conductor for applying potentials for the control of the electron current and/or for screening purposes.

A detector of this kind may consequently take the place of a usual detector or three-electrode-amplifying valve for it likewise comprises both an emitting electrode and an electrode which does not or substantially does not emit and, between these two electrodes, a grid which corresponds to a grid arranged in a valve in the vacuum between the cathode and the anode. In accordance with the invention, the grid is located in the insulating layer, which, as has been found, has the most favorable result. It is clear that the number of grids need not be limited to one.

A favorable form of execution of an electrode system according to the invention is that which follows:

The grids are constituted by perforated layers of conductive material which are contained in the insulating intermediate layer, said perforated layers being obtained, for example, by applying to one of the electrodes alternately an insulating layer and a perforated conductive layer and finally to the last conductive layer again an insulating layer. It is consequently possible to form electrode systems which correspond to the present radio valves having three or more electrodes such as, for example, the triodes, tetrodes, pentodes, hexodes, etc.

It is particularly important and advantageous that the insulating intermediate layer which contains the grids be formed independently of the adjacent electrode layers, for this renders it possible to control at will both the thickness of the layer and the position of the grids. The intermediate layer may be constituted of, for example, artificial resin which is applied in liquid condition to one of the electrodes. It is thus possible to apply a perfectly homogeneous layer.

It is of course very desirable to make the intermediate layer as thin as possible in order to raise as much as possible the electrical field strength between the main electrodes, as this has a great effect on the favorable operation. Due to the presence of a conductive grid there arises however the possibility that due to the too slight thickness of the insulating layer at a single, for example, accidentally projecting point, said grid may short-circuit one of the electrodes. In one favorable form of execution the risk of a short circuit is avoided by providing the grids with an insulating coating before they are applied to the insulating layer.

When choosing a grid material it should be considered that on account of its own emission a grid of emitting material acts upon the electron current between the anode and the cathode.

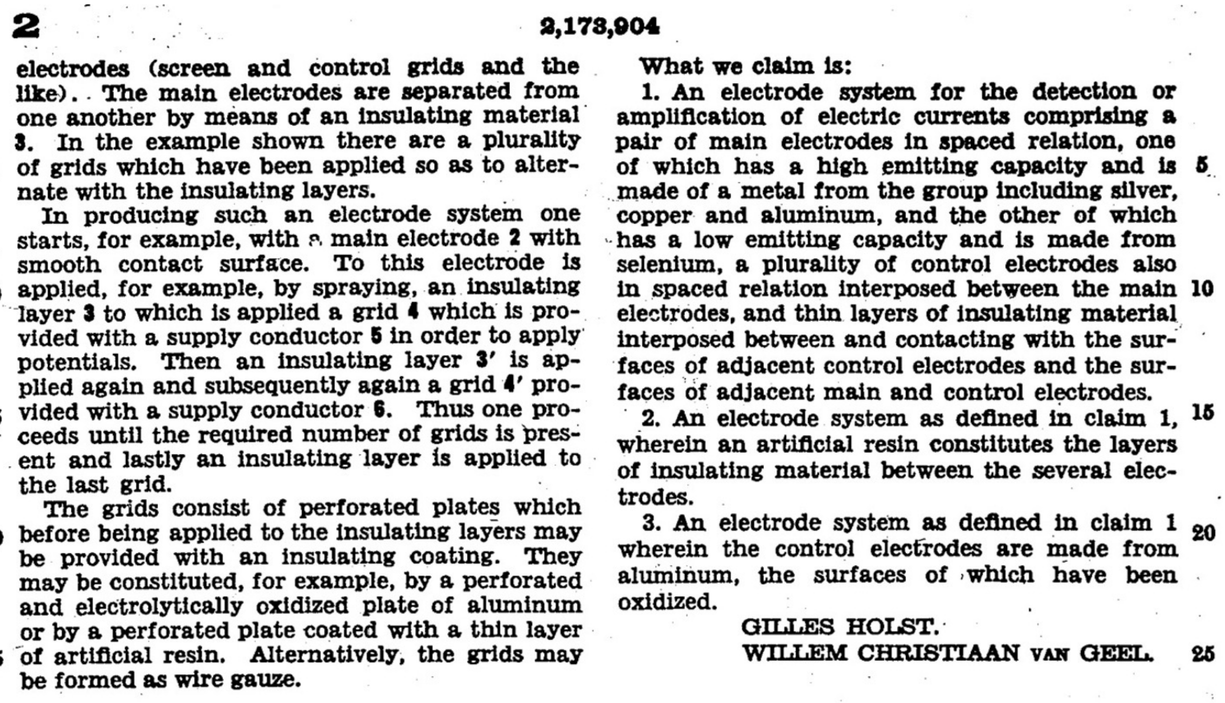
According to a favorable mode of execution use is therefore made of a grid material being a semi- or bad conductor and having a slight emitting capacity.

The invention will be explained more fully with reference to the accompanying drawing which represents, by way of example, one embodiment thereof.

The main electrodes 1 and 2 are formed, respectively, by a conductor consisting of a metal of high emitting capacity such as aluminum, copper or silver and by a semi-conductor as is usual in dry rectifiers. Selenium is a very suitable material for the semi-conductor.

The drawing represents, by way of example, a six-electrode-system. Besides the main electrodes 1 and 2 there are consequently four further

Figure B.31: Gilles Holst and Willem Christiaan van Geel filed a patent application on transistors in 1935.



2 2,173,904

electrodes (screen and control grids and the like). The main electrodes are separated from one another by means of an insulating material 3. In the example shown there are a plurality of grids which have been applied so as to alternate with the insulating layers.

In producing such an electrode system one starts, for example, with a main electrode 2 with smooth contact surface. To this electrode is applied, for example, by spraying, an insulating layer 3 to which is applied a grid 4 which is provided with a supply conductor 5 in order to apply potentials. Then an insulating layer 3' is applied again and subsequently again a grid 4' provided with a supply conductor 6. Thus one proceeds until the required number of grids is present and lastly an insulating layer is applied to the last grid.

The grids consist of perforated plates which before being applied to the insulating layers may be provided with an insulating coating. They may be constituted, for example, by a perforated and electrolytically oxidized plate of aluminum or by a perforated plate coated with a thin layer of artificial resin. Alternatively, the grids may be formed as wire gauze.

What we claim is:

1. An electrode system for the detection or amplification of electric currents comprising a pair of main electrodes in spaced relation, one of which has a high emitting capacity and is made of a metal from the group including silver, copper and aluminum, and the other of which has a low emitting capacity and is made from selenium, a plurality of control electrodes also in spaced relation interposed between the main electrodes, and thin layers of insulating material interposed between and contacting with the surfaces of adjacent control electrodes and the surfaces of adjacent main and control electrodes.

2. An electrode system as defined in claim 1, wherein an artificial resin constitutes the layers of insulating material between the several electrodes.

3. An electrode system as defined in claim 1 wherein the control electrodes are made from aluminum, the surfaces of which have been oxidized.

GILLES HOLST.
WILLEM CHRISTIAAN VAN GEEL.

Figure B.32: Gilles Holst and Willem Christiaan van Geel filed a patent application on transistors in 1935.

[**4. Rudolf Hilsch (German, 1903–1972) and Robert Pohl (German, 1884–1976)** demonstrated a proof-of-concept point-contact transistor in 1938:

> Rudolf Hilsch and Robert Pohl. 1938. Steuerung von Elektronenströmen mit einem Dreielektrodenkristall und ein Modell einer Sperrschicht. *Zeitschrift für Physik* 111:399–408.

Like a modern transistor, this solid-state semiconductor device had three electrodes, with the current flow into the middle electrode (the base, in modern terminology) controlling and greatly amplified by the much larger current flow between the other two electrodes (see pp. 2691–2692). For the 1938 experiments, that signal amplification was approximately a factor of 20. These results were extremely impressive, but the reason they are best described as "proof of concept" is that they were obtained in a material (a potassium bromide crystal) that became a good semiconductor only at a very high temperature (490^oC) and high voltages (100–150 Volts), which would not be practical for use in normal electronic circuits.

Hilsch recognized those limitations and promptly proposed that the results be replicated by modifying existing room-temperature semiconductor diodes to add a third electrode for the base (see below and p. 2693):

> Rudolf Hilsch. 1939. Elektronenleitung in Kristallen. *Die Naturwissenschaften* 27:489–492.

From available documentation, it is unclear exactly what projects Hilsch worked on between 1939 and the postwar period. Given his determination to replicate the transistor amplifier results in a more practical semiconductor device, and given the extensive wartime work on new and improved semiconductor devices, it seems likely that he would have carried his transistor work further, or collaborated with other scientists to do so.

In any event, the 1938 Hilsch and Pohl paper and the 1939 Hilsch paper were published in physics journals that were highly regarded and widely read in the German-speaking world, so they would have encouraged many other scientists (such as those mentioned in this appendix) to try to replicate, extend, and apply that work.

At the end of World War II, both Hilsch and Pohl were extensively interrogated by scientists and officials from Allied countries in order to aid postwar electronics programs in those countries (see for example pp. 2997 and 3005).]

Rudolf Hilsch. 1939. Elektronenleitung in Kristallen. *Die Naturwissenschaften* 27:489–492.

Durch diese Messung ist zum erstenmal gezeigt worden, daß man auch in festen Körpern Ströme steuern kann. Die Trägheit der Ströme in diesem "großen" Modell ist naturgemäß groß. Es ist jetzt nur eine Aufgabe der Technik, auch in den dünnen Sperrschichten der technischen Gleichrichter das Steuergitter unterzubringen. Wenn die Lösung dieser Aufgabe gelingt, kann der Dreielektroden-Kristall auch technisch neben dem Dreielektroden-Rohr seine Bedeutung erhalten.	This measurement has shown for the first time that it is also possible to control currents in solid bodies. The inertia of the currents in this "large" model is naturally large. It is now only a technical task to add the control grid in the thin barrier layers of engineering rectifiers. If the solution to this problem is successful, the three-electrode crystal can also gain technical significance alongside the three-electrode tube.

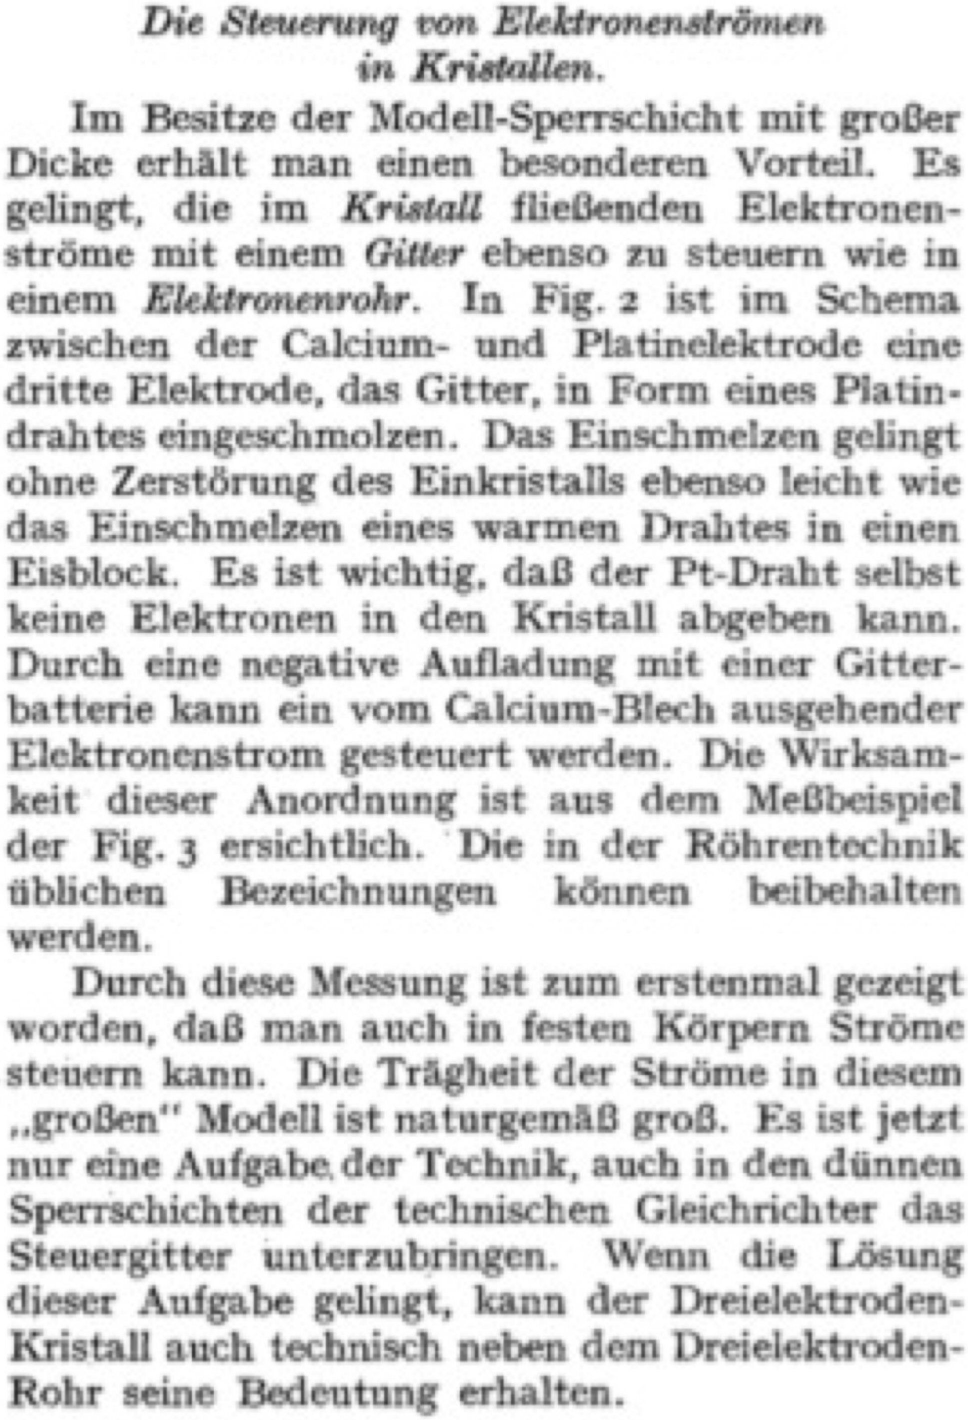
Rudolf Hilsch. 1939. Elektronenleitung in Kristallen. *Die Naturwissenschaften* 27:489–492.



Die Steuerung von Elektronenströmen in Kristallen.

Im Besitze der Modell-Sperrschicht mit großer Dicke erhält man einen besonderen Vorteil. Es gelingt, die im *Kristall* fließenden Elektronenströme mit einem *Gitter* ebenso zu steuern wie in einem *Elektronenrohr*. In Fig. 2 ist im Schema zwischen der Calcium- und Platinelektrode eine dritte Elektrode, das Gitter, in Form eines Platindrahtes eingeschmolzen. Das Einschmelzen gelingt ohne Zerstörung des Einkristalls ebenso leicht wie das Einschmelzen eines warmen Drahtes in einen Eisblock. Es ist wichtig, daß der Pt-Draht selbst keine Elektronen in den Kristall abgeben kann. Durch eine negative Aufladung mit einer Gitterbatterie kann ein vom Calcium-Blech ausgehender Elektronenstrom gesteuert werden. Die Wirksamkeit dieser Anordnung ist aus dem Meßbeispiel der Fig. 3 ersichtlich. Die in der Röhrentechnik üblichen Bezeichnungen können beibehalten werden.

Durch diese Messung ist zum erstenmal gezeigt worden, daß man auch in festen Körpern Ströme steuern kann. Die Trägheit der Ströme in diesem „großen" Modell ist naturgemäß groß. Es ist jetzt nur eine Aufgabe der Technik, auch in den dünnen Sperrschichten der technischen Gleichrichter das Steuergitter unterzubringen. Wenn die Lösung dieser Aufgabe gelingt, kann der Dreielektroden-Kristall auch technisch neben dem Dreielektroden-Rohr seine Bedeutung erhalten.

Figure B.35: Rudolf Hilsch and Robert Pohl demonstrated a prototype point-contact transistor in 1938.

[**5. Erich Habann (German, 1892–1968)** filed a very detailed patent application on point-contact transistors, their fabrication, and use:

> Erich Habann. Filed in 1942. German patent DE 971,775. Einrichtung zur Verstärkung elektrischer Ströme und Spannungen. [Device for Amplifying Electrical Currents and Voltages.] (pp. 2695–2698)

The level of detail in the patent application suggests that by 1942, Habann may well have already produced and demonstrated such transistors at his Hessenwinkel laboratory (p. 2699).

Although documentation on his transistor results is not currently available, it is known that Habann worked on a number of secretive research projects involving electronics, rockets, and nuclear physics during the war, and that he was well funded by the German military. After the war, he continued his research for the Soviet Union.

If Habann indeed had a working prototype transistor by 1942, it is possible that such transistors may have been mass-produced for use in rocket guidance systems or other applications before the end of the war.

It is also quite possible that Habann, his hardware, and his information directly or indirectly aided the development of microelectronics technologies in Allied countries after the war.

It appears that thus far only the German historian Günter Nagel has investigated and briefly written about Erich Habann and his inventions:

> Günter Nagel. 2006. Pionier der Funktechnik. *Brandenburger Blätter.* 15 December 2006 p. 9.
>
> Günter Nagel. 2011. *Himmlers Waffenforscher: Physiker, Chemiker, Mathematiker und Techniker im Dienste der SS.* Aachen: Helios.
>
> Günter Nagel. 2012a. *Wissenschaft für den Krieg: Die geheimen Arbeiten der Abteilung Forschung des Heereswaffenamtes.* Stuttgart: Franz Steiner.

Much more archival research should be conducted to investigate Habann's technical accomplishments, as well as their direct and indirect impacts on other research programs.]

Einrichtung zur Verstärkung elektrischer Ströme und Spannungen

Patentiert im Gebiet der Bundesrepublik Deutschland vom 22. September 1942 an
Der Zeitraum vom 8. Mai 1945 bis einschließlich 7. Mai 1950 wird auf die Patentdauer nicht angerechnet
(Ges. v. 15. 7. 1951)
Patentanmeldung bekanntgemacht am 20. August 1953
Patenterteilung bekanntgemacht am 12. März 1959

Die Erfindung benutzt zur Verstärkung elektrischer Ströme oder Spannungen einen Trockengleichrichter. Dieser besteht z. B. beim Selentrockengleichrichter aus Selen in kristallisiertem Zustande als Halbleiter, das sich als dünne Schicht zwischen zwei Elektroden befindet, die bei gleicher Feldstärke als Kathoden verschieden große Elektronenströme in das Selen hineinzusenden vermögen. Je unterschiedlicher die beiden Elektroden in ihrer Emissionsfähigkeit sind, desto besser arbeitet der Gleichrichter. In der Praxis wird Selen bei so hoher Temperatur auf einer Nickelunterlage geschmolzen, daß sich zwischen dem Nickel und dem Selen eine dünne Schicht von Nickelselenid bildet. Dieses Nickelselenid vermag als Kathode nur sehr geringe Elektronenmengen in das Selen zu emittieren, im Gegensatz zu den Metallen wie Cadmium, Blei, die als Kathoden bei gleich großer Feldstärke erheblich größere Elektronenmengen in das Selen hineinzusenden vermögen. Die Metalle selbst unterscheiden sich im übrigen nur wenig in ihrem Emissionsvermögen untereinander. Eine Selenschicht, die sich zwischen einer Nickelselenidelektrode auf der einen Seite

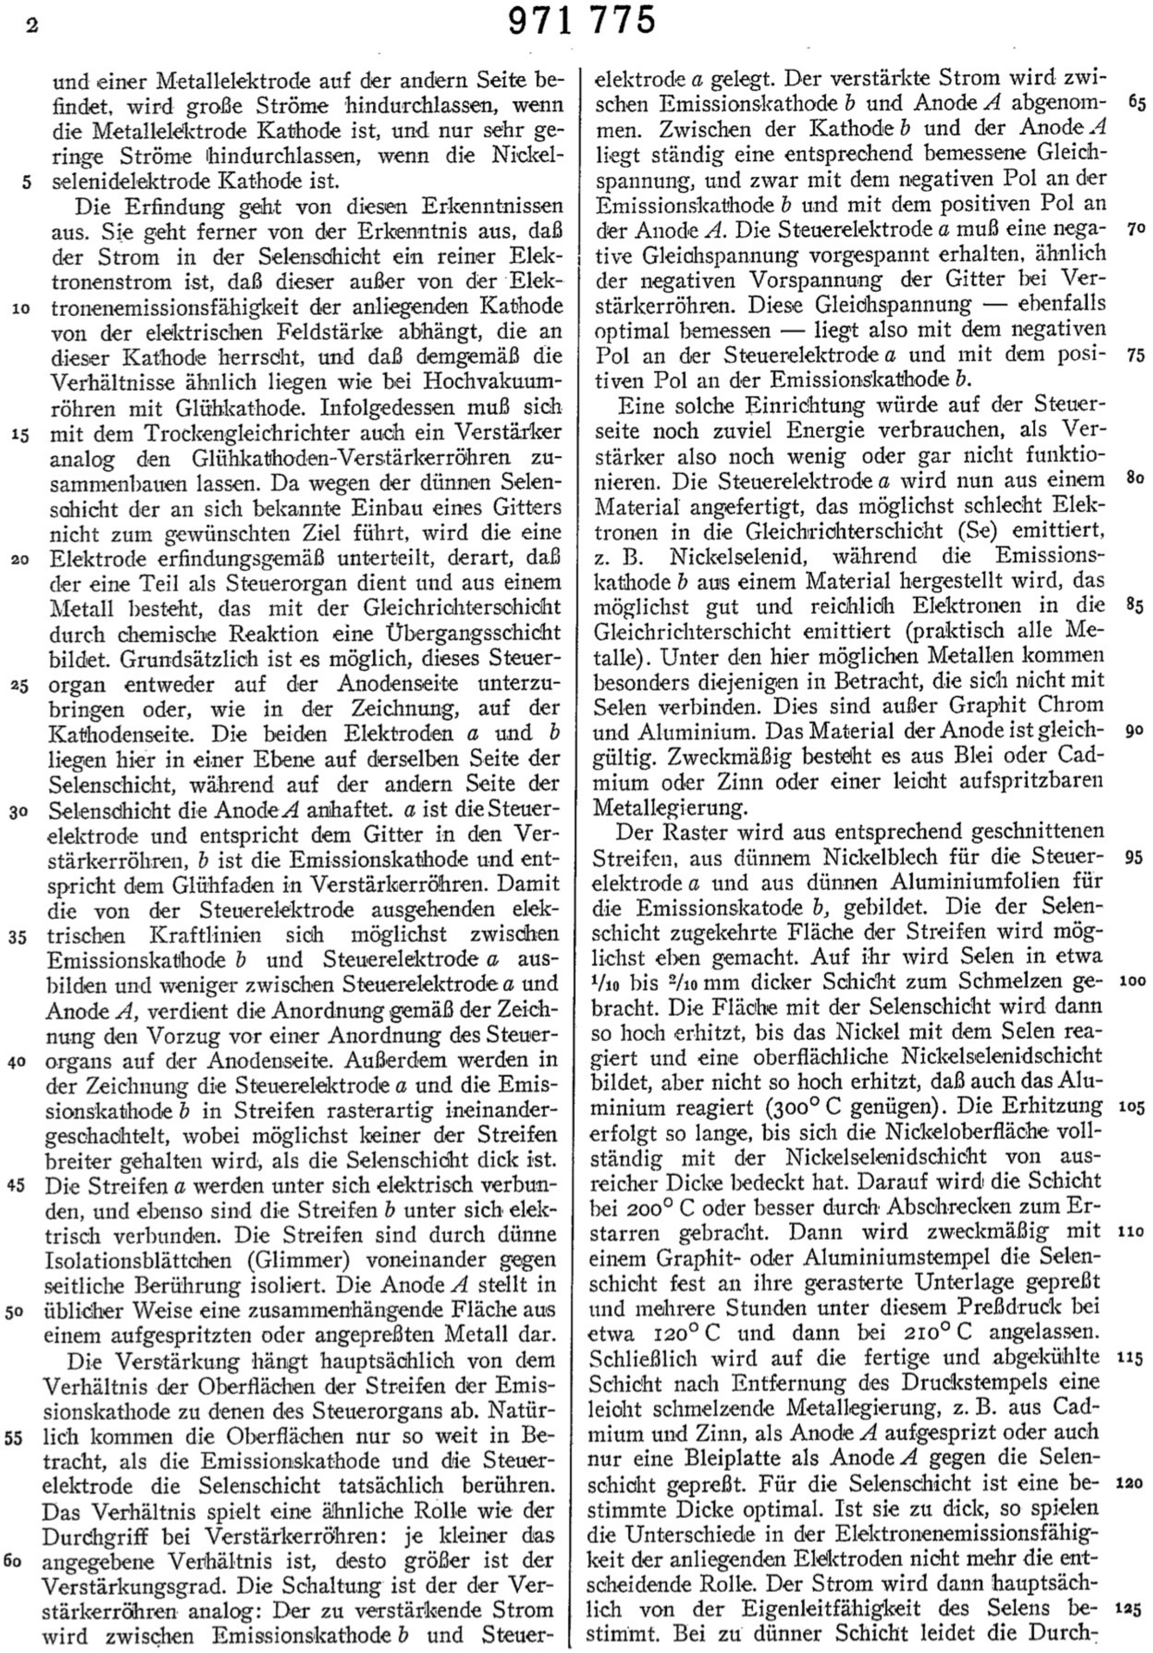
Figure B.36: In 1942, Erich Habann filed a detailed patent application on point-contact transistors, their fabrication, and use.



und einer Metallelektrode auf der andern Seite befindet, wird große Ströme hindurchlassen, wenn die Metallelektrode Kathode ist, und nur sehr geringe Ströme hindurchlassen, wenn die Nickelselenidelektrode Kathode ist.

Die Erfindung geht von diesen Erkenntnissen aus. Sie geht ferner von der Erkenntnis aus, daß der Strom in der Selenschicht ein reiner Elektronenstrom ist, daß dieser außer von der Elektronenemissionsfähigkeit der anliegenden Kathode von der elektrischen Feldstärke abhängt, die an dieser Kathode herrscht, und daß demgemäß die Verhältnisse ähnlich liegen wie bei Hochvakuumröhren mit Glühkathode. Infolgedessen muß sich mit dem Trockengleichrichter auch ein Verstärker analog den Glühkathoden-Verstärkerröhren zusammenbauen lassen. Da wegen der dünnen Selenschicht der an sich bekannte Einbau eines Gitters nicht zum gewünschten Ziel führt, wird die eine Elektrode erfindungsgemäß unterteilt, derart, daß der eine Teil als Steuerorgan dient und aus einem Metall besteht, das mit der Gleichrichterschicht durch chemische Reaktion eine Übergangsschicht bildet. Grundsätzlich ist es möglich, dieses Steuerorgan entweder auf der Anodenseite unterzubringen oder, wie in der Zeichnung, auf der Kathodenseite. Die beiden Elektroden *a* und *b* liegen hier in einer Ebene auf derselben Seite der Selenschicht, während auf der andern Seite der Selenschicht die Anode *A* anhaftet. *a* ist die Steuerelektrode und entspricht dem Gitter in den Verstärkerröhren, *b* ist die Emissionskathode und entspricht dem Glühfaden in Verstärkerröhren. Damit die von der Steuerelektrode ausgehenden elektrischen Kraftlinien sich möglichst zwischen Emissionskathode *b* und Steuerelektrode *a* ausbilden und weniger zwischen Steuerelektrode *a* und Anode *A*, verdient die Anordnung gemäß der Zeichnung den Vorzug vor einer Anordnung des Steuerorgans auf der Anodenseite. Außerdem werden in der Zeichnung die Steuerelektrode *a* und die Emissionskathode *b* in Streifen rasterartig ineinandergeschachtelt, wobei möglichst keiner der Streifen breiter gehalten wird, als die Selenschicht dick ist. Die Streifen *a* werden unter sich elektrisch verbunden, und ebenso sind die Streifen *b* unter sich elektrisch verbunden. Die Streifen sind durch dünne Isolationsblättchen (Glimmer) voneinander gegen seitliche Berührung isoliert. Die Anode *A* stellt in üblicher Weise eine zusammenhängende Fläche aus einem aufgespritzten oder angepreßten Metall dar.

Die Verstärkung hängt hauptsächlich von dem Verhältnis der Oberflächen der Streifen der Emissionskathode zu denen des Steuerorgans ab. Natürlich kommen die Oberflächen nur so weit in Betracht, als die Emissionskathode und die Steuerelektrode die Selenschicht tatsächlich berühren. Das Verhältnis spielt eine ähnliche Rolle wie der Durchgriff bei Verstärkerröhren: je kleiner das angegebene Verhältnis ist, desto größer ist der Verstärkungsgrad. Die Schaltung ist der der Verstärkerröhren analog: Der zu verstärkende Strom wird zwischen Emissionskathode *b* und Steuerelektrode *a* gelegt. Der verstärkte Strom wird zwischen Emissionskathode *b* und Anode *A* abgenommen. Zwischen der Kathode *b* und der Anode *A* liegt ständig eine entsprechend bemessene Gleichspannung, und zwar mit dem negativen Pol an der Emissionskathode *b* und mit dem positiven Pol an der Anode *A*. Die Steuerelektrode *a* muß eine negative Gleichspannung vorgespannt erhalten, ähnlich der negativen Vorspannung der Gitter bei Verstärkerröhren. Diese Gleichspannung — ebenfalls optimal bemessen — liegt also mit dem negativen Pol an der Steuerelektrode *a* und mit dem positiven Pol an der Emissionskathode *b*.

Eine solche Einrichtung würde auf der Steuerseite noch zuviel Energie verbrauchen, als Verstärker also noch wenig oder gar nicht funktionieren. Die Steuerelektrode *a* wird nun aus einem Material angefertigt, das möglichst schlecht Elektronen in die Gleichrichterschicht (Se) emittiert, z. B. Nickelselenid, während die Emissionskathode *b* aus einem Material hergestellt wird, das möglichst gut und reichlich Elektronen in die Gleichrichterschicht emittiert (praktisch alle Metalle). Unter den hier möglichen Metallen kommen besonders diejenigen in Betracht, die sich nicht mit Selen verbinden. Dies sind außer Graphit Chrom und Aluminium. Das Material der Anode ist gleichgültig. Zweckmäßig besteht es aus Blei oder Cadmium oder Zinn oder einer leicht aufspritzbaren Metallegierung.

Der Raster wird aus entsprechend geschnittenen Streifen, aus dünnem Nickelblech für die Steuerelektrode *a* und aus dünnen Aluminiumfolien für die Emissionskatode *b*, gebildet. Die der Selenschicht zugekehrte Fläche der Streifen wird möglichst eben gemacht. Auf ihr wird Selen in etwa $^{1}/_{10}$ bis $^{2}/_{10}$ mm dicker Schicht zum Schmelzen gebracht. Die Fläche mit der Selenschicht wird dann so hoch erhitzt, bis das Nickel mit dem Selen reagiert und eine oberflächliche Nickelselenidschicht bildet, aber nicht so hoch erhitzt, daß auch das Aluminium reagiert (300° C genügen). Die Erhitzung erfolgt so lange, bis sich die Nickeloberfläche vollständig mit der Nickelselenidschicht von ausreicher Dicke bedeckt hat. Darauf wird die Schicht bei 200° C oder besser durch Abschrecken zum Erstarren gebracht. Dann wird zweckmäßig mit einem Graphit- oder Aluminiumstempel die Selenschicht fest an ihre gerasterte Unterlage gepreßt und mehrere Stunden unter diesem Preßdruck bei etwa 120° C und dann bei 210° C angelassen. Schließlich wird auf die fertige und abgekühlte Schicht nach Entfernung des Druckstempels eine leicht schmelzende Metallegierung, z. B. aus Cadmium und Zinn, als Anode *A* aufgesprizt oder auch nur eine Bleiplatte als Anode *A* gegen die Selenschicht gepreßt. Für die Selenschicht ist eine bestimmte Dicke optimal. Ist sie zu dick, so spielen die Unterschiede in der Elektronenemissionsfähigkeit der anliegenden Elektroden nicht mehr die entscheidende Rolle. Der Strom wird dann hauptsächlich von der Eigenleitfähigkeit des Selens bestimmt. Bei zu dünner Schicht leidet die Durch-

Figure B.37: In 1942, Erich Habann filed a detailed patent application on point-contact transistors, their fabrication, and use.

schlagsfestigkeit, und die konstruktiven Schwierigkeiten werden zu groß. Die optimale Schichtdicke liegt beim Selen zwischen 1/10 und 2/10 mm.

Es besteht ein Interesse, zur Verringerung ihrer Kapazität die Streifen *a* und *b* möglichst klein zu machen. An Stelle der Streifen werden besser dünne Drähte aus Nickel und Aluminium verwendet, die gemeinsam über eine Porzellanunterlage, die entsprechende Rillen hat, gewickelt werden, und zwar derart, daß die Drähte einlagig und abwechselnd, lediglich durch die Porzellanrillen isoliert, dicht nebeneinander auf der Porzellanfläche liegen.

Der Verstärker arbeitet trägheitslos. Er kann, wenn der Anodenkreis mit dem Steuerkreis rückgekoppelt wird, als Generator dienen, oder er kann mit weiteren Verstärkern in Reihe geschaltet werden, indem der aus dem Anodenkreis des ersten Verstärkers resultierende Strom über einen Transformator oder ein sonstiges geeignetes Kopplungsglied dem Steuerkreis des zweiten Verstärkers zugeleitet wird usw. Es können so hohe Verstärkungen erzielt werden. Andererseits können mehrere Verstärker auch parallel geschaltet und so der Aufnahme und der verstärkten Wiedergabe auch größerer Leistungen angepaßt werden. Es besteht die Möglichkeit, diese Anpassung von vornherein durch Bemessung der gesamten Selenfläche vorzunehmen.

Eine höhere Anodenspannung liefert ohne weiteres eine größere Leistung. Die positive Anodenspannung wird aber dadurch begrenzt, daß von der Steuerelektrode *a*, die ja gegenüber allen andern Elektroden, insbesondere gegenüber der Anode *A* negativ ist, nicht nur kein größerer Strom zur Emissionskathode *b*, sondern auch nicht zur Anode *A* hinüberfließen darf. Insofern müssen Anodenspannung und Vorspannung des Steuergitters einander optimal angepaßt sein. Die Leistung des Verstärkers kann weiterhin durch Kühlflächen, welche die Temperatur der Selenschicht beim Betriebe niedrig halten, gesteigert werden.

Die Erfindung ist nicht auf den Selengleichrichter beschränkt. In gleicher Weise können andere Gleichrichtertypen verwendet werden. Beim Kupferoxydulgleichrichter beispielsweise entspricht das Kupferoxydul der Selenschicht und das Kupferoxyd der Nickelselenidschicht. Die Steuerelektrode wird daher hier einen dünnen Überzug von Kupferoxyd erhalten müssen und erst mit diesem die Kupferoxydulschicht berühren dürfen. Das Material der Anode ist auch hier gleichgültig, während die Emissionskathode zweckmäßig aus reinem Kupfer besteht.

PATENTANSPRÜCHE:

1. Einrichtung zur Verstärkung elektrischer Ströme und Spannungen mittels einer von drei Elektroden oberflächlich berührten Gleichrichterschicht, bei der eine Elektrode als Steuerelektrode dient, dadurch gekennzeichnet, daß auf der einen Seite der Gleichrichterschicht eine zusammenhängende Elektrode anliegt, während die auf der anderen Seite liegende Elektrode unterteilt ist, derart, daß der eine Teil als Steuerelektrode dient und aus einem Metall besteht, das mit der Gleichrichterschicht durch chemische Reaktion eine Übergangsschicht bildet.

2. Einrichtung nach Anspruch 1, dadurch gekennzeichnet, daß bei einer aus einer Verbindung bestehenden Gleichrichterschicht, wie Kupferoxydul, die Übergangsschicht statt durch Reaktion des Metalls der Steuerelektrode mit der Gleichrichterschicht durch Reaktion eines Metalloides (Sauerstoff) mit der Gleichrichterschicht gebildet ist.

3. Einrichtung nach Anspruch 1 oder 2, dadurch gekennzeichnet, daß die beiden auf derselben Seite der Gleichrichterschicht benachbarten Elektroden rasterartig oder rostartig ineinander verschachtelt sind, derart, daß die ineinandergreifenden Teile eng nebeneinander liegen und eine Breite besitzen, die vorzugsweise kleiner als die Stärke der Gleichrichterschicht ist.

4. Einrichtung nach den Ansprüchen 1 bis 3, dadurch gekennzeichnet, daß die Steuerelektrode von größerer Flächenausdehnung als die neben ihr angeordnete Elektrode ist.

5. Einrichtung nach den Ansprüchen 1 bis 4, dadurch gekennzeichnet, daß die Veränderung der von der Steuerelektrode beaufschlagten Flächenteile der Gleichrichterschicht als kontinuierlicher Übergang durch thermische Behandlung erzielt ist.

6. Einrichtung nach Anspruch 5, dadurch gekennzeichnet, daß die optimale Stärke der Übergangsschicht durch die Höhe der angewandten Temperatur und die Dauer der Erhitzung bestimmt ist.

7. Einrichtung nach den Ansprüchen 1 bis 7, dadurch gekennzeichnet, daß die anderen Elektroden aus einem Material bestehen, das sich nicht mit der Gleichrichterschicht verbindet.

8. Einrichtung nach den Ansprüchen 1 bis 7, dadurch gekennzeichnet, daß die der Steuerelektrode benachbarte Elektrode die Anode darstellt.

9. Einrichtung nach den Ansprüchen 1 bis 7, dadurch gekennzeichnet, daß die der Steuerelektrode benachbarte Elektrode die Kathode darstellt.

10. Einrichtung nach den Ansprüchen 1 bis 9, dadurch gekennzeichnet, daß Mittel zur Kühlung (Kühlflächen) vorgesehen sind.

Verhältnisse bei unvollständiger Störstellendissoziation. 12. Anwendung auf den Kupferoxydulgleichrichter. (Zusammenfassung am Schluß.)

Das genauere Studium der Kupferoxydul- und Selengleichrichter 1) hat zu der Erkenntnis geführt, daß bei diesen beiden Gleichrichteranordnungen, die bisher als die technisch wichtigsten anzusehen sind, eine völlige Ionisierung der (Defekt-)Elektronen abgebenden Störstellen in einer etwa 10^{-5} cm dicken, unmittelbar an das Gleichrichtermetall angrenzenden Schicht des Halbleiters anzunehmen ist. Ferner hat sich herausgestellt, daß das Gleich- und Wechselstromverhalten dieser Gleichrichter ganz überwiegend durch die Eigenschaften dieser „Erschöpfungsrandschicht" („Durchführung", S. 235) bestimmt ist, während die Schichten, in denen eine unvollkommene Ionisierung der Störstellen oder eine teilweise Kompensation der Störstellenladungen durch (Defekt-)Elektronenladungen vorhanden sind, nur eine geringe Rolle spielen.

Diese Erkenntnis ist nicht nur von physikalischem und technischem Interesse, sondern ermöglicht auch eine stark vereinfachte mathematische Darstellung der für diesen Gleichrichtertyp maßgebenden Erscheinungen;

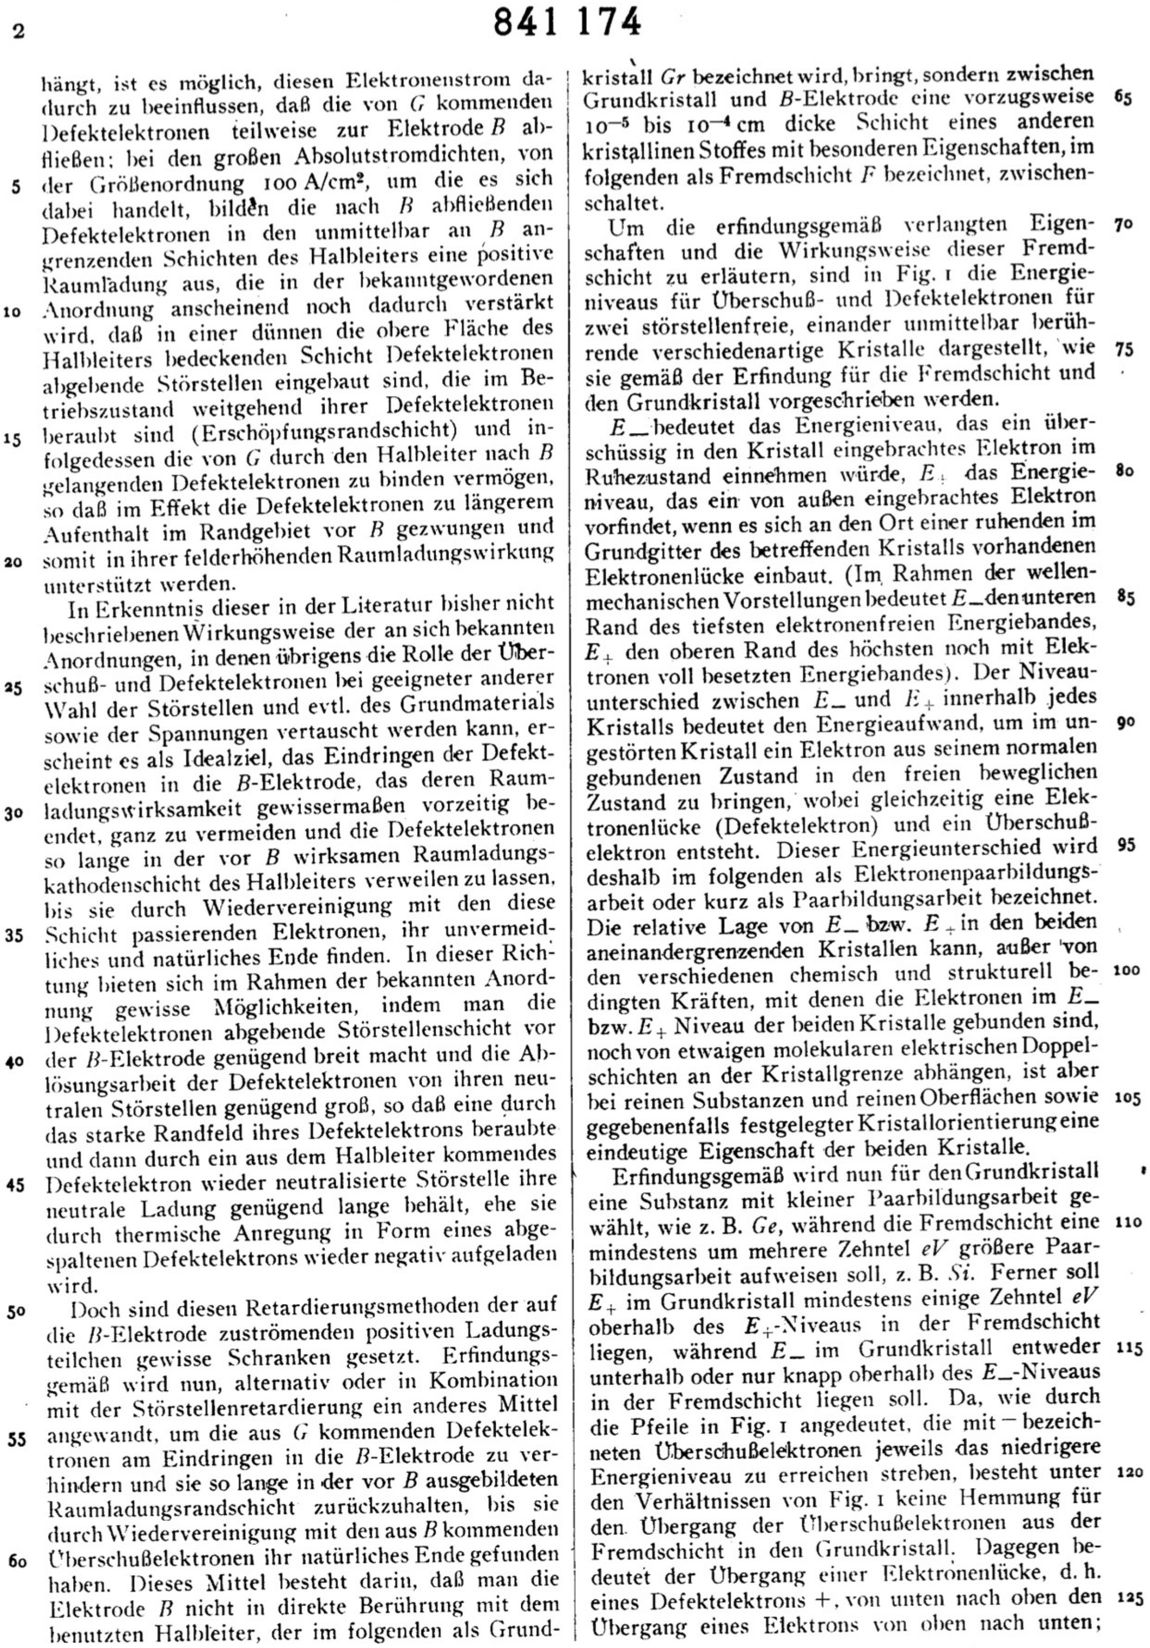
Halbleiteranordnung

Patentiert im Gebiet der Bundesrepublik Deutschland vom 2. Oktober 1948 an
Patentanmeldung bekanntgemacht am 21. Dezember 1950
Patenterteilung bekanntgemacht am 24. April 1952

Es sind Anordnungen bekanntgeworden, bei denen ein Störstellenhalbleiter (Germanium) von beispielsweise flachzylindrischer Form so mit Elektroden versehen wird, daß die Grundfläche mit einer großen, im folgenden als *O*-Elektrode bezeichneten Metallelektrode im Kontakt ist, während auf der oberen Fläche eine Metallspitze mit positivem Potential von etwa 1 V gegen die *O*-Elektrode als Steuerelektrode, im folgenden als *G* bezeichnet, dient und eine etwa $^1/_{10}$ mm davon entfernt aufgesetzte Spitze, im folgenden mit *B* bezeichnet, den zu beeinflussenden Strom nach der *O*-Elektrode abführt; die *B*-Elektrode hat hierbei ein negatives Potential von etwa 10 V gegen die *O*-Elektrode.

Die Steuerwirkung derartiger Anordnungen beruht darauf, daß die *G*-Elektrode bei den gewählten Betriebsspannungen einen durch kleine Änderungen von U_g stark variierenden Strom von Defektelektronen in den Halbleiter entsendet, wobei dieser Halbleiter infolge eines gewissen Zusatzes von Elektronen abgebenden Störstellen als Überschußhalbleiter wirkt. Die *B*-Elektrode, die als Kathode gegenüber der *O*-Elektrode geschaltet ist, stößt die Überschußelektroden des Halbleiters ab und vermag, solange kein *G*-Strom fließt, nur dadurch einen Strom zu führen, daß Elektronen aus *B* in den Halbleiter entsendet werden, was bei dem gewählten Halbleiter bedeutend höhere Spannungen erfordert als in umgekehrter Richtung zur Emission von Defektelektronen notwendig sind. Da unter diesen Bedingungen die Elektronenemission von der an der *B*-Elektrode herrschenden Feldstärke ab-

Figure B.42: Walter Schottky published detailed analyses of semiconductor properties necessary for transistors in 1942.



2

841 174

hängt, ist es möglich, diesen Elektronenstrom dadurch zu beeinflussen, daß die von *G* kommenden Defektelektronen teilweise zur Elektrode *B* abfließen; bei den großen Absolutstromdichten, von der Größenordnung 100 A/cm², um die es sich dabei handelt, bilden die nach *B* abfließenden Defektelektronen in den unmittelbar an *B* angrenzenden Schichten des Halbleiters eine positive Raumladung aus, die in der bekanntgewordenen Anordnung anscheinend noch dadurch verstärkt wird, daß in einer dünnen die obere Fläche des Halbleiters bedeckenden Schicht Defektelektronen abgebende Störstellen eingebaut sind, die im Betriebszustand weitgehend ihrer Defektelektronen beraubt sind (Erschöpfungsrandschicht) und infolgedessen die von *G* durch den Halbleiter nach *B* gelangenden Defektelektronen zu binden vermögen, so daß im Effekt die Defektelektronen zu längerem Aufenthalt im Randgebiet vor *B* gezwungen und somit in ihrer felderhöhenden Raumladungswirkung unterstützt werden.

In Erkenntnis dieser in der Literatur bisher nicht beschriebenen Wirkungsweise der an sich bekannten Anordnungen, in denen übrigens die Rolle der Überschuß- und Defektelektronen bei geeigneter anderer Wahl der Störstellen und evtl. des Grundmaterials sowie der Spannungen vertauscht werden kann, erscheint es als Idealziel, das Eindringen der Defektelektronen in die *B*-Elektrode, das deren Raumladungswirksamkeit gewissermaßen vorzeitig beendet, ganz zu vermeiden und die Defektelektronen so lange in der vor *B* wirksamen Raumladungskathodenschicht des Halbleiters verweilen zu lassen, bis sie durch Wiedervereinigung mit den diese Schicht passierenden Elektronen, ihr unvermeidliches und natürliches Ende finden. In dieser Richtung bieten sich im Rahmen der bekannten Anordnung gewisse Möglichkeiten, indem man die Defektelektronen abgebende Störstellenschicht vor der *B*-Elektrode genügend breit macht und die Ablösungsarbeit der Defektelektronen von ihren neutralen Störstellen genügend groß, so daß eine durch das starke Randfeld ihres Defektelektrons beraubte und dann durch ein aus dem Halbleiter kommendes Defektelektron wieder neutralisierte Störstelle ihre neutrale Ladung genügend lange behält, ehe sie durch thermische Anregung in Form eines abgespaltenen Defektelektrons wieder negativ aufgeladen wird.

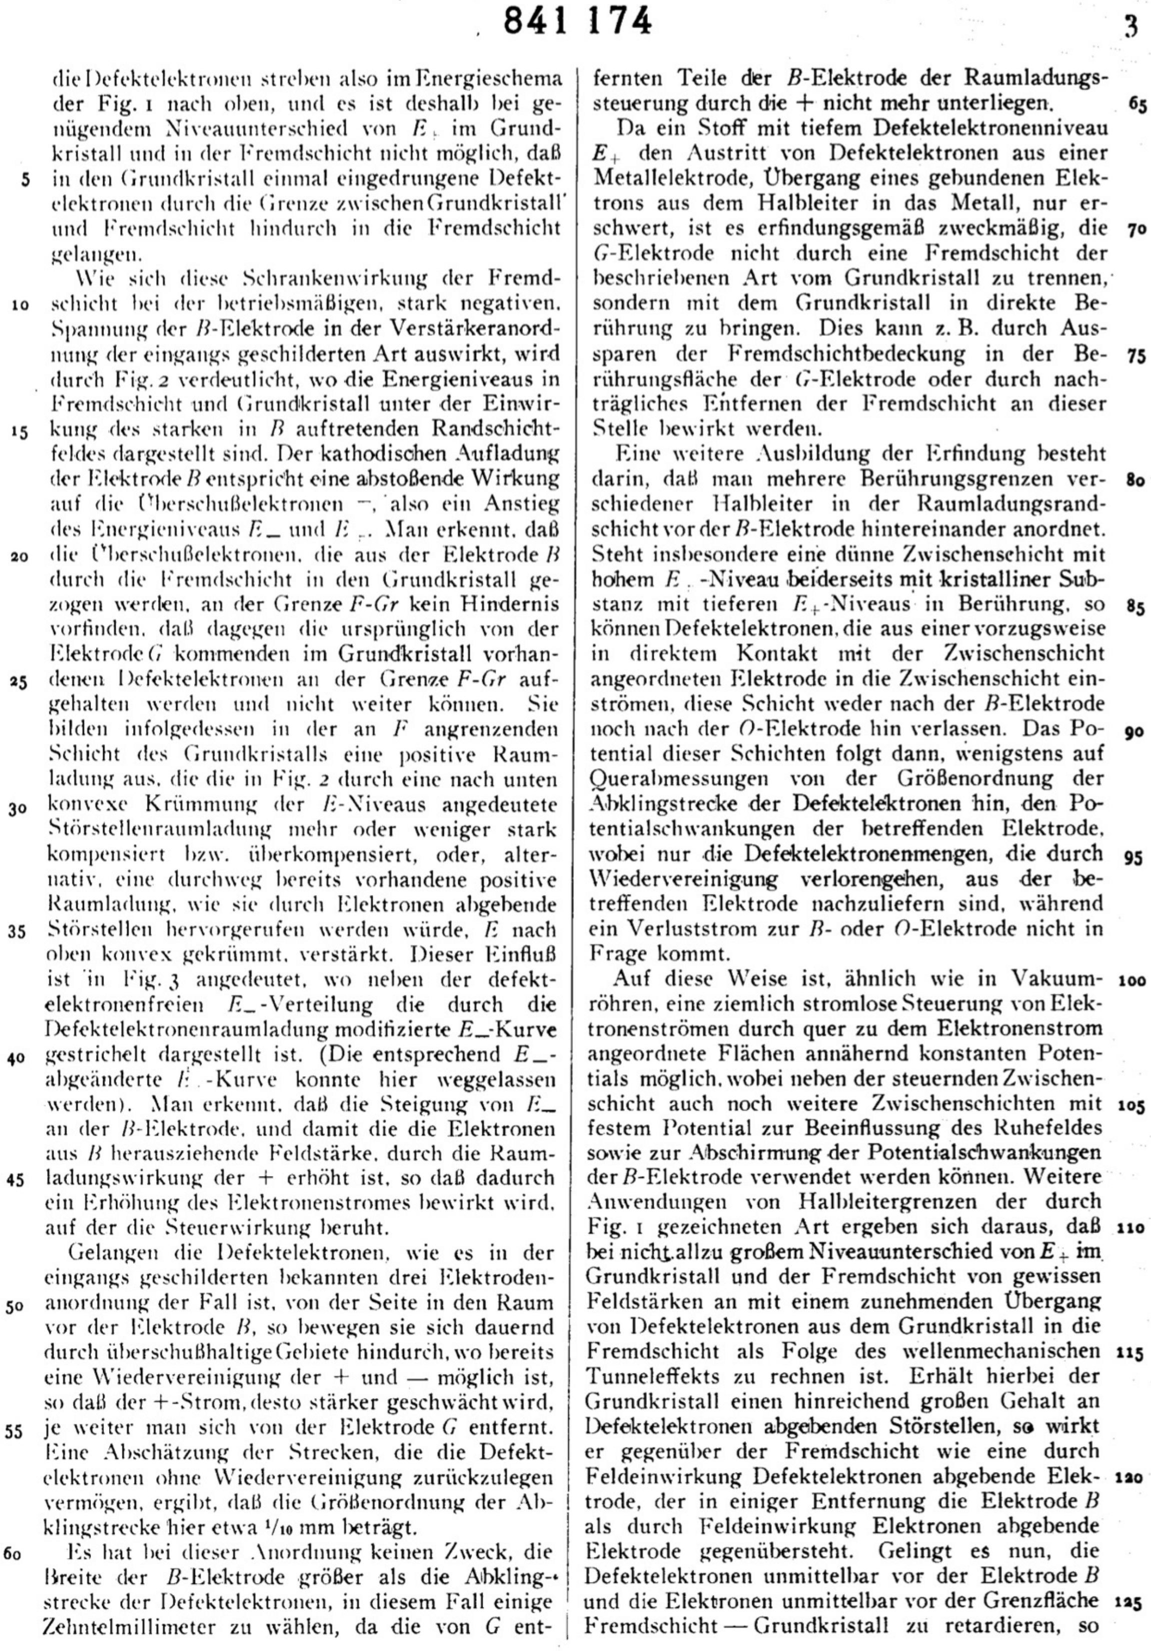
Doch sind diesen Retardierungsmethoden der auf die *B*-Elektrode zuströmenden positiven Ladungsteilchen gewisse Schranken gesetzt. Erfindungsgemäß wird nun, alternativ oder in Kombination mit der Störstellenretardierung ein anderes Mittel angewandt, um die aus *G* kommenden Defektelektronen am Eindringen in die *B*-Elektrode zu verhindern und sie so lange in der vor *B* ausgebildeten Raumladungsrandschicht zurückzuhalten, bis sie durch Wiedervereinigung mit den aus *B* kommenden Überschußelektronen ihr natürliches Ende gefunden haben. Dieses Mittel besteht darin, daß man die Elektrode *B* nicht in direkte Berührung mit dem benutzten Halbleiter, der im folgenden als Grundkristall *Gr* bezeichnet wird, bringt, sondern zwischen Grundkristall und *B*-Elektrode eine vorzugsweise 10^{-5} bis 10^{-4} cm dicke Schicht eines anderen kristallinen Stoffes mit besonderen Eigenschaften, im folgenden als Fremdschicht *F* bezeichnet, zwischenschaltet.

Um die erfindungsgemäß verlangten Eigenschaften und die Wirkungsweise dieser Fremdschicht zu erläutern, sind in Fig. 1 die Energieniveaus für Überschuß- und Defektelektronen für zwei störstellenfreie, einander unmittelbar berührende verschiedenartige Kristalle dargestellt, wie sie gemäß der Erfindung für die Fremdschicht und den Grundkristall vorgeschrieben werden.

E_- bedeutet das Energieniveau, das ein überschüssig in den Kristall eingebrachtes Elektron im Ruhezustand einnehmen würde, E_+ das Energieniveau, das ein von außen eingebrachtes Elektron vorfindet, wenn es sich an den Ort einer ruhenden im Grundgitter des betreffenden Kristalls vorhandenen Elektronenlücke einbaut. (Im Rahmen der wellenmechanischen Vorstellungen bedeutet E_- den unteren Rand des tiefsten elektronenfreien Energiebandes, E_+ den oberen Rand des höchsten noch mit Elektronen voll besetzten Energiebandes). Der Niveauunterschied zwischen E_- und E_+ innerhalb jedes Kristalls bedeutet den Energieaufwand, um im ungestörten Kristall ein Elektron aus seinem normalen gebundenen Zustand in den freien beweglichen Zustand zu bringen, wobei gleichzeitig eine Elektronenlücke (Defektelektron) und ein Überschußelektron entsteht. Dieser Energieunterschied wird deshalb im folgenden als Elektronenpaarbildungsarbeit oder kurz als Paarbildungsarbeit bezeichnet. Die relative Lage von E_- bzw. E_+ in den beiden aneinandergrenzenden Kristallen kann, außer von den verschiedenen chemisch und strukturell bedingten Kräften, mit denen die Elektronen im E_- bzw. E_+ Niveau der beiden Kristalle gebunden sind, noch von etwaigen molekularen elektrischen Doppelschichten an der Kristallgrenze abhängen, ist aber bei reinen Substanzen und reinen Oberflächen sowie gegebenenfalls festgelegter Kristallorientierung eine eindeutige Eigenschaft der beiden Kristalle.

Erfindungsgemäß wird nun für den Grundkristall eine Substanz mit kleiner Paarbildungsarbeit gewählt, wie z. B. *Ge*, während die Fremdschicht eine mindestens um mehrere Zehntel *eV* größere Paarbildungsarbeit aufweisen soll, z. B. *Si*. Ferner soll E_+ im Grundkristall mindestens einige Zehntel *eV* oberhalb des E_+-Niveaus in der Fremdschicht liegen, während E_- im Grundkristall entweder unterhalb oder nur knapp oberhalb des E_--Niveaus in der Fremdschicht liegen soll. Da, wie durch die Pfeile in Fig. 1 angedeutet, die mit $-$ bezeichneten Überschußelektronen jeweils das niedrigere Energieniveau zu erreichen streben, besteht unter den Verhältnissen von Fig. 1 keine Hemmung für den Übergang der Überschußelektronen aus der Fremdschicht in den Grundkristall. Dagegen bedeutet der Übergang einer Elektronenlücke, d. h. eines Defektelektrons +, von unten nach oben den Übergang eines Elektrons von oben nach unten;

Figure B.43: Walter Schottky published detailed analyses of semiconductor properties necessary for transistors in 1942.



die Defektelektronen streben also im Energieschema der Fig. 1 nach oben, und es ist deshalb bei genügendem Niveauunterschied von E_+ im Grundkristall und in der Fremdschicht nicht möglich, daß in den Grundkristall einmal eingedrungene Defektelektronen durch die Grenze zwischen Grundkristall und Fremdschicht hindurch in die Fremdschicht gelangen.

Wie sich diese Schrankenwirkung der Fremdschicht bei der betriebsmäßigen, stark negativen. Spannung der *B*-Elektrode in der Verstärkeranordnung der eingangs geschilderten Art auswirkt, wird durch Fig. 2 verdeutlicht, wo die Energieniveaus in Fremdschicht und Grundkristall unter der Einwirkung des starken in *B* auftretenden Randschichtfeldes dargestellt sind. Der kathodischen Aufladung der Elektrode *B* entspricht eine abstoßende Wirkung auf die Überschußelektronen −, also ein Anstieg des Energieniveaus E_- und E_+. Man erkennt, daß die Überschußelektronen, die aus der Elektrode *B* durch die Fremdschicht in den Grundkristall gezogen werden, an der Grenze *F-Gr* kein Hindernis vorfinden, daß dagegen die ursprünglich von der Elektrode *G* kommenden im Grundkristall vorhandenen Defektelektronen an der Grenze *F-Gr* aufgehalten werden und nicht weiter können. Sie bilden infolgedessen in der an *F* angrenzenden Schicht des Grundkristalls eine positive Raumladung aus, die die in Fig. 2 durch eine nach unten konvexe Krümmung der *E*-Niveaus angedeutete Störstellenraumladung mehr oder weniger stark kompensiert bzw. überkompensiert, oder, alternativ, eine durchweg bereits vorhandene positive Raumladung, wie sie durch Elektronen abgebende Störstellen hervorgerufen werden würde, *E* nach oben konvex gekrümmt, verstärkt. Dieser Einfluß ist in Fig. 3 angedeutet, wo neben der defektelektronenfreien E_--Verteilung die durch die Defektelektronenraumladung modifizierte E_--Kurve gestrichelt dargestellt ist. (Die entsprechend E_--abgeänderte E_+-Kurve konnte hier weggelassen werden). Man erkennt, daß die Steigung von E_- an der *B*-Elektrode, und damit die die Elektronen aus *B* herausziehende Feldstärke, durch die Raumladungswirkung der + erhöht ist, so daß dadurch ein Erhöhung des Elektronenstromes bewirkt wird, auf der die Steuerwirkung beruht.

Gelangen die Defektelektronen, wie es in der eingangs geschilderten bekannten drei Elektrodenanordnung der Fall ist, von der Seite in den Raum vor der Elektrode *B*, so bewegen sie sich dauernd durch überschußhaltige Gebiete hindurch, wo bereits eine Wiedervereinigung der + und — möglich ist, so daß der +-Strom, desto stärker geschwächt wird, je weiter man sich von der Elektrode *G* entfernt. Eine Abschätzung der Strecken, die die Defektelektronen ohne Wiedervereinigung zurückzulegen vermögen, ergibt, daß die Größenordnung der Abklingstrecke hier etwa 1/10 mm beträgt.

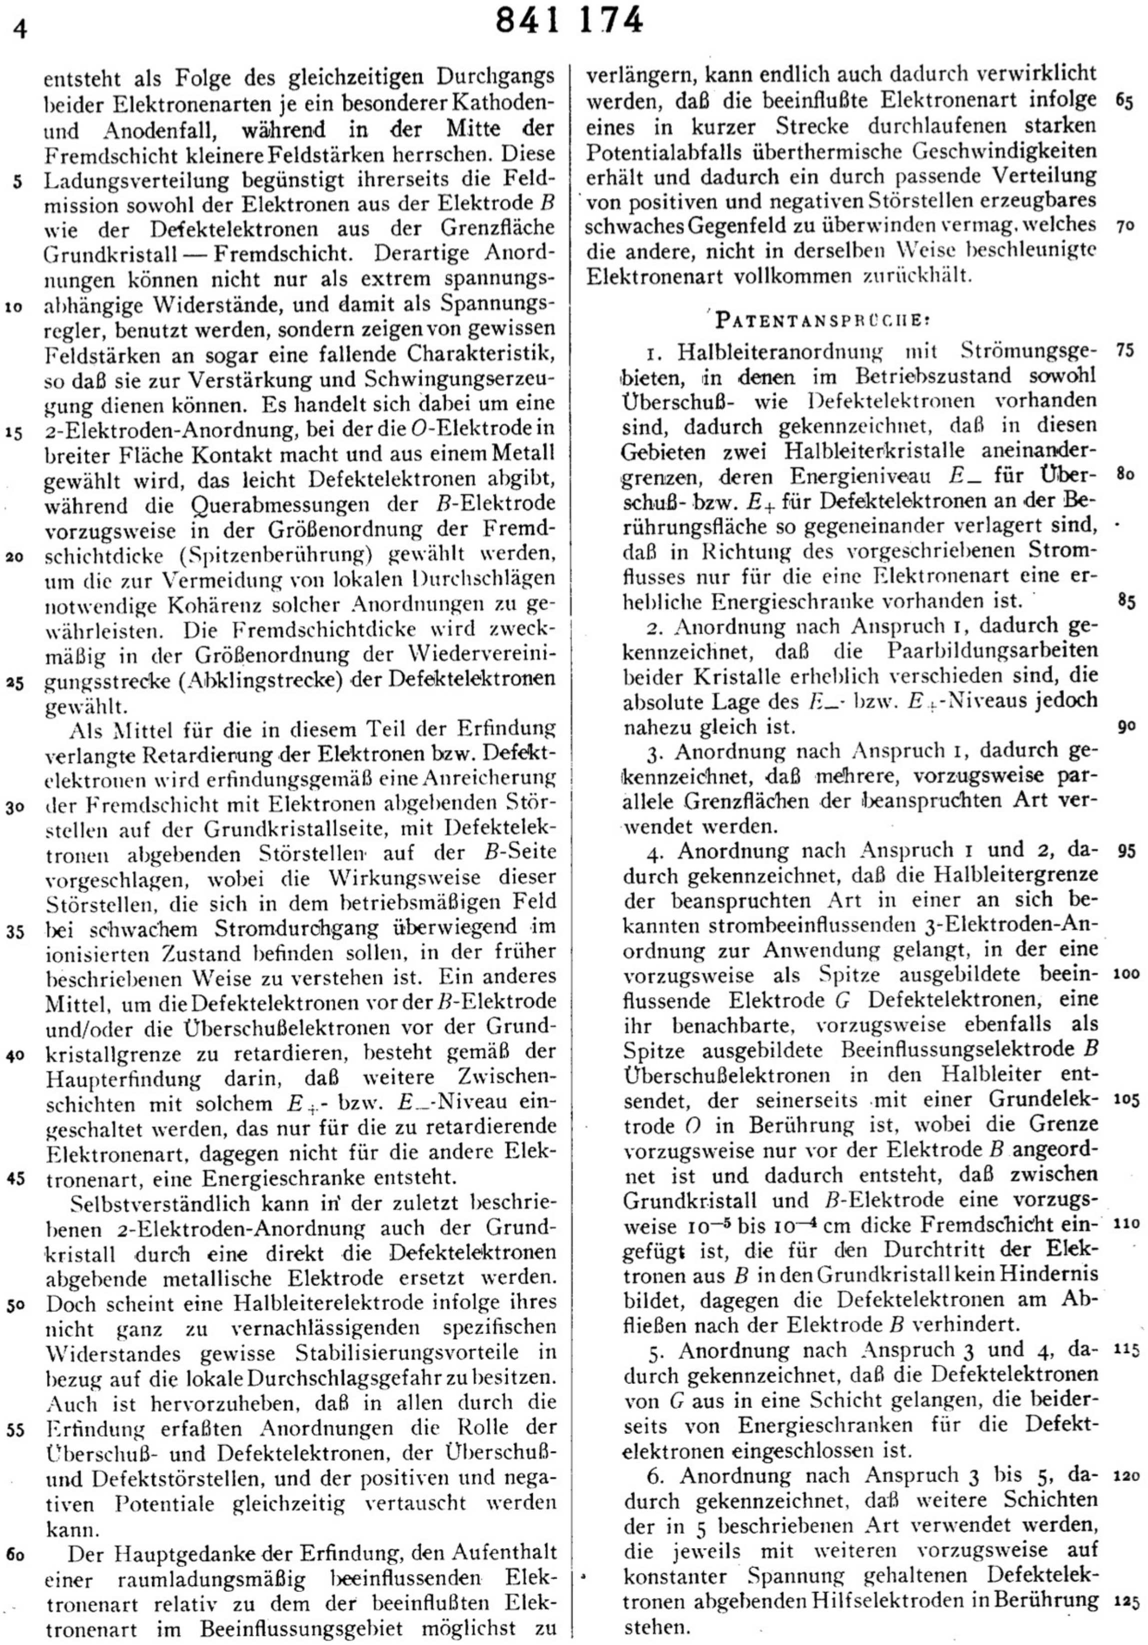
Es hat bei dieser Anordnung keinen Zweck, die Breite der *B*-Elektrode größer als die Abklingstrecke der Defektelektronen, in diesem Fall einige Zehntelmillimeter zu wählen, da die von *G* entfernten Teile der *B*-Elektrode der Raumladungssteuerung durch die + nicht mehr unterliegen.

Da ein Stoff mit tiefem Defektelektronenniveau E_+ den Austritt von Defektelektronen aus einer Metallelektrode, Übergang eines gebundenen Elektrons aus dem Halbleiter in das Metall, nur erschwert, ist es erfindungsgemäß zweckmäßig, die *G*-Elektrode nicht durch eine Fremdschicht der beschriebenen Art vom Grundkristall zu trennen, sondern mit dem Grundkristall in direkte Berührung zu bringen. Dies kann z. B. durch Aussparen der Fremdschichtbedeckung in der Berührungsfläche der *G*-Elektrode oder durch nachträgliches Entfernen der Fremdschicht an dieser Stelle bewirkt werden.

Eine weitere Ausbildung der Erfindung besteht darin, daß man mehrere Berührungsgrenzen verschiedener Halbleiter in der Raumladungsrandschicht vor der *B*-Elektrode hintereinander anordnet. Steht insbesondere eine dünne Zwischenschicht mit hohem E_+-Niveau beiderseits mit kristalliner Substanz mit tieferen E_+-Niveaus in Berührung, so können Defektelektronen, die aus einer vorzugsweise in direktem Kontakt mit der Zwischenschicht angeordneten Elektrode in die Zwischenschicht einströmen, diese Schicht weder nach der *B*-Elektrode noch nach der *O*-Elektrode hin verlassen. Das Potential dieser Schichten folgt dann, wenigstens auf Querabmessungen von der Größenordnung der Abklingstrecke der Defektelektronen hin, den Potentialschwankungen der betreffenden Elektrode, wobei nur die Defektelektronenmengen, die durch Wiedervereinigung verlorengehen, aus der betreffenden Elektrode nachzuliefern sind, während ein Verluststrom zur *B*- oder *O*-Elektrode nicht in Frage kommt.

Auf diese Weise ist, ähnlich wie in Vakuumröhren, eine ziemlich stromlose Steuerung von Elektronenströmen durch quer zu dem Elektronenstrom angeordnete Flächen annähernd konstanten Potentials möglich, wobei neben der steuernden Zwischenschicht auch noch weitere Zwischenschichten mit festem Potential zur Beeinflussung des Ruhefeldes sowie zur Abschirmung der Potentialschwankungen der *B*-Elektrode verwendet werden können. Weitere Anwendungen von Halbleitergrenzen der durch Fig. 1 gezeichneten Art ergeben sich daraus, daß bei nicht allzu großem Niveauunterschied von E_+ im Grundkristall und der Fremdschicht von gewissen Feldstärken an mit einem zunehmenden Übergang von Defektelektronen aus dem Grundkristall in die Fremdschicht als Folge des wellenmechanischen Tunneleffekts zu rechnen ist. Erhält hierbei der Grundkristall einen hinreichend großen Gehalt an Defektelektronen abgebenden Störstellen, so wirkt er gegenüber der Fremdschicht wie eine durch Feldeinwirkung Defektelektronen abgebende Elektrode, der in einiger Entfernung die Elektrode *B* als durch Feldeinwirkung Elektronen abgebende Elektrode gegenübersteht. Gelingt es nun, die Defektelektronen unmittelbar vor der Elektrode *B* und die Elektronen unmittelbar vor der Grenzfläche Fremdschicht — Grundkristall zu retardieren, so

Figure B.44: Walter Schottky published detailed analyses of semiconductor properties necessary for transistors in 1942.



4

841 174

entsteht als Folge des gleichzeitigen Durchgangs beider Elektronenarten je ein besonderer Kathoden- und Anodenfall, während in der Mitte der Fremdschicht kleinere Feldstärken herrschen. Diese Ladungsverteilung begünstigt ihrerseits die Feldmission sowohl der Elektronen aus der Elektrode *B* wie der Defektelektronen aus der Grenzfläche Grundkristall — Fremdschicht. Derartige Anordnungen können nicht nur als extrem spannungsabhängige Widerstände, und damit als Spannungsregler, benutzt werden, sondern zeigen von gewissen Feldstärken an sogar eine fallende Charakteristik, so daß sie zur Verstärkung und Schwingungserzeugung dienen können. Es handelt sich dabei um eine 2-Elektroden-Anordnung, bei der die *O*-Elektrode in breiter Fläche Kontakt macht und aus einem Metall gewählt wird, das leicht Defektelektronen abgibt, während die Querabmessungen der *B*-Elektrode vorzugsweise in der Größenordnung der Fremdschichtdicke (Spitzenberührung) gewählt werden, um die zur Vermeidung von lokalen Durchschlägen notwendige Kohärenz solcher Anordnungen zu gewährleisten. Die Fremdschichtdicke wird zweckmäßig in der Größenordnung der Wiedervereinigungsstrecke (Abklingstrecke) der Defektelektronen gewählt.

Als Mittel für die in diesem Teil der Erfindung verlangte Retardierung der Elektronen bzw. Defektelektronen wird erfindungsgemäß eine Anreicherung der Fremdschicht mit Elektronen abgebenden Störstellen auf der Grundkristallseite, mit Defektelektronen abgebenden Störstellen auf der *B*-Seite vorgeschlagen, wobei die Wirkungsweise dieser Störstellen, die sich in dem betriebsmäßigen Feld bei schwachem Stromdurchgang überwiegend im ionisierten Zustand befinden sollen, in der früher beschriebenen Weise zu verstehen ist. Ein anderes Mittel, um die Defektelektronen vor der *B*-Elektrode und/oder die Überschußelektronen vor der Grundkristallgrenze zu retardieren, besteht gemäß der Haupterfindung darin, daß weitere Zwischenschichten mit solchem E_+- bzw. E_--Niveau eingeschaltet werden, das nur für die zu retardierende Elektronenart, dagegen nicht für die andere Elektronenart, eine Energieschranke entsteht.

Selbstverständlich kann in der zuletzt beschriebenen 2-Elektroden-Anordnung auch der Grundkristall durch eine direkt die Defektelektronen abgebende metallische Elektrode ersetzt werden. Doch scheint eine Halbleiterelektrode infolge ihres nicht ganz zu vernachlässigenden spezifischen Widerstandes gewisse Stabilisierungsvorteile in bezug auf die lokale Durchschlagsgefahr zu besitzen. Auch ist hervorzuheben, daß in allen durch die Erfindung erfaßten Anordnungen die Rolle der Überschuß- und Defektelektronen, der Überschuß- und Defektstörstellen, und der positiven und negativen Potentiale gleichzeitig vertauscht werden kann.

Der Hauptgedanke der Erfindung, den Aufenthalt einer raumladungsmäßig beeinflussenden Elektronenart relativ zu dem der beeinflußten Elektronenart im Beeinflussungsgebiet möglichst zu verlängern, kann endlich auch dadurch verwirklicht werden, daß die beeinflußte Elektronenart infolge eines in kurzer Strecke durchlaufenen starken Potentialabfalls überthermische Geschwindigkeiten erhält und dadurch ein durch passende Verteilung von positiven und negativen Störstellen erzeugbares schwaches Gegenfeld zu überwinden vermag, welches die andere, nicht in derselben Weise beschleunigte Elektronenart vollkommen zurückhält.

PATENTANSPRÜCHE:

1. Halbleiteranordnung mit Strömungsgebieten, in denen im Betriebszustand sowohl Überschuß- wie Defektelektronen vorhanden sind, dadurch gekennzeichnet, daß in diesen Gebieten zwei Halbleiterkristalle aneinandergrenzen, deren Energieniveau E_- für Überschuß- bzw. E_+ für Defektelektronen an der Berührungsfläche so gegeneinander verlagert sind, daß in Richtung des vorgeschriebenen Stromflusses nur für die eine Elektronenart eine erhebliche Energieschranke vorhanden ist.

2. Anordnung nach Anspruch 1, dadurch gekennzeichnet, daß die Paarbildungsarbeiten beider Kristalle erheblich verschieden sind, die absolute Lage des E_-- bzw. E_+-Niveaus jedoch nahezu gleich ist.

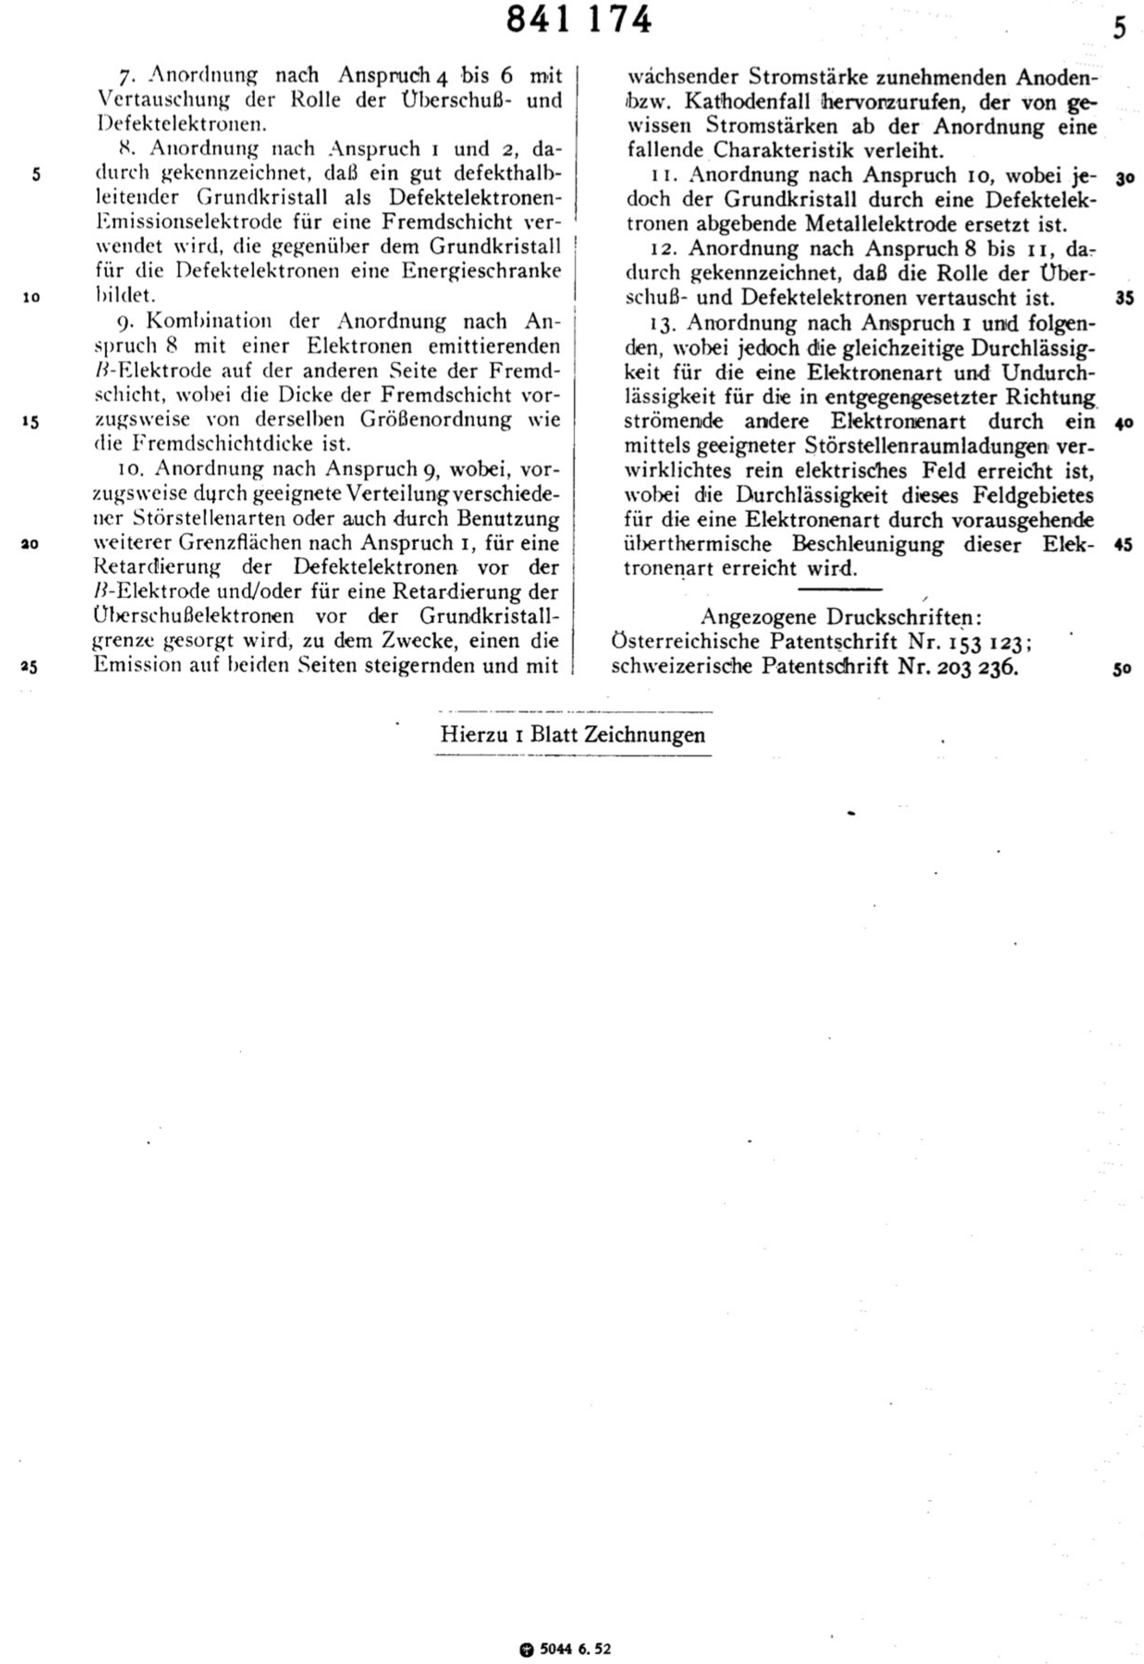
3. Anordnung nach Anspruch 1, dadurch gekennzeichnet, daß mehrere, vorzugsweise parallele Grenzflächen der beanspruchten Art verwendet werden.

4. Anordnung nach Anspruch 1 und 2, dadurch gekennzeichnet, daß die Halbleitergrenze der beanspruchten Art in einer an sich bekannten strombeeinflussenden 3-Elektroden-Anordnung zur Anwendung gelangt, in der eine vorzugsweise als Spitze ausgebildete beeinflussende Elektrode *G* Defektelektronen, eine ihr benachbarte, vorzugsweise ebenfalls als Spitze ausgebildete Beeinflussungselektrode *B* Überschußelektronen in den Halbleiter entsendet, der seinerseits mit einer Grundelektrode *O* in Berührung ist, wobei die Grenze vorzugsweise nur vor der Elektrode *B* angeordnet ist und dadurch entsteht, daß zwischen Grundkristall und *B*-Elektrode eine vorzugsweise 10^{-5} bis 10^{-4} cm dicke Fremdschicht eingefügt ist, die für den Durchtritt der Elektronen aus *B* in den Grundkristall kein Hindernis bildet, dagegen die Defektelektronen am Abfließen nach der Elektrode *B* verhindert.

5. Anordnung nach Anspruch 3 und 4, dadurch gekennzeichnet, daß die Defektelektronen von *G* aus in eine Schicht gelangen, die beiderseits von Energieschranken für die Defektelektronen eingeschlossen ist.

6. Anordnung nach Anspruch 3 bis 5, dadurch gekennzeichnet, daß weitere Schichten der in 5 beschriebenen Art verwendet werden, die jeweils mit weiteren vorzugsweise auf konstanter Spannung gehaltenen Defektelektronen abgebenden Hilfselektroden in Berührung stehen.

Figure B.45: Walter Schottky published detailed analyses of semiconductor properties necessary for transistors in 1942.



841 174

5

7. Anordnung nach Anspruch 4 bis 6 mit Vertauschung der Rolle der Überschuß- und Defektelektronen.

8. Anordnung nach Anspruch 1 und 2, dadurch gekennzeichnet, daß ein gut defekthalbleitender Grundkristall als Defektelektronen-Emissionselektrode für eine Fremdschicht verwendet wird, die gegenüber dem Grundkristall für die Defektelektronen eine Energieschranke bildet.

9. Kombination der Anordnung nach Anspruch 8 mit einer Elektronen emittierenden *B*-Elektrode auf der anderen Seite der Fremdschicht, wobei die Dicke der Fremdschicht vorzugsweise von derselben Größenordnung wie die Fremdschichtdicke ist.

10. Anordnung nach Anspruch 9, wobei, vorzugsweise durch geeignete Verteilung verschiedener Störstellenarten oder auch durch Benutzung weiterer Grenzflächen nach Anspruch 1, für eine Retardierung der Defektelektronen vor der *B*-Elektrode und/oder für eine Retardierung der Überschußelektronen vor der Grundkristallgrenze gesorgt wird, zu dem Zwecke, einen die Emission auf beiden Seiten steigernden und mit wachsender Stromstärke zunehmenden Anoden- bzw. Kathodenfall hervorzurufen, der von gewissen Stromstärken ab der Anordnung eine fallende Charakteristik verleiht.

11. Anordnung nach Anspruch 10, wobei jedoch der Grundkristall durch eine Defektelektronen abgebende Metallelektrode ersetzt ist.

12. Anordnung nach Anspruch 8 bis 11, dadurch gekennzeichnet, daß die Rolle der Überschuß- und Defektelektronen vertauscht ist.

13. Anordnung nach Anspruch 1 und folgenden, wobei jedoch die gleichzeitige Durchlässigkeit für die eine Elektronenart und Undurchlässigkeit für die in entgegengesetzter Richtung strömende andere Elektronenart durch ein mittels geeigneter Störstellenraumladungen verwirklichtes rein elektrisches Feld erreicht ist, wobei die Durchlässigkeit dieses Feldgebietes für die eine Elektronenart durch vorausgehende überthermische Beschleunigung dieser Elektronenart erreicht wird.

February 19, 1947

Dear Mr. Webb,

this is to confirm a telephone discussion with you of today on the matter of additional data on Selenium Rectifier developments in Germany.

Up to now the following reports on German developments have been released in USA:

PB-67, PB-423, PB-425, PB-916, PB-18781,
PB-21981, PB-25662 and PB-32591.

All of these reports discuss the methods and problems of SAF; one report only, namely PB-18781 (by H. Dauber), discusses certain aspects of AEG and Siemens work on rectifiers and one, namely PB-25662, gives some comparison between AEG and SAF rectifiers.

thus of the three selenium rectifier manufactiriers in Germany, two — AEG and Siemens — have not been overexploited.

there were three research centers on Selenium rectifiers in Germany: at Darmstadt headed by Dr. Brill and H. Krebbs, ~~at~~ in Prague headed by Prof. Gudden and the third of the Siemens Co headed by Dr. Schottky.

A complete summary of the Darmstadt group has been obtained and reported by me and Col. Ranger. A good summary of the Prague group has been given by Harry Dauber in his report. on a basis of a large file of documents and data removed from Gudden's laboratory in Prague. But no trace yet has been found of Dr. Schottky's files removed. from him by some officers early in 1945.

Figure B.48: Walter Schottky published detailed analyses of semiconductor properties necessary for transistors in 1942. All of his papers were seized by the United States in 1945 and never returned [NARA RG 40, Entry UD-75, Box 24, Folder Selenium Rectifier Machinery].

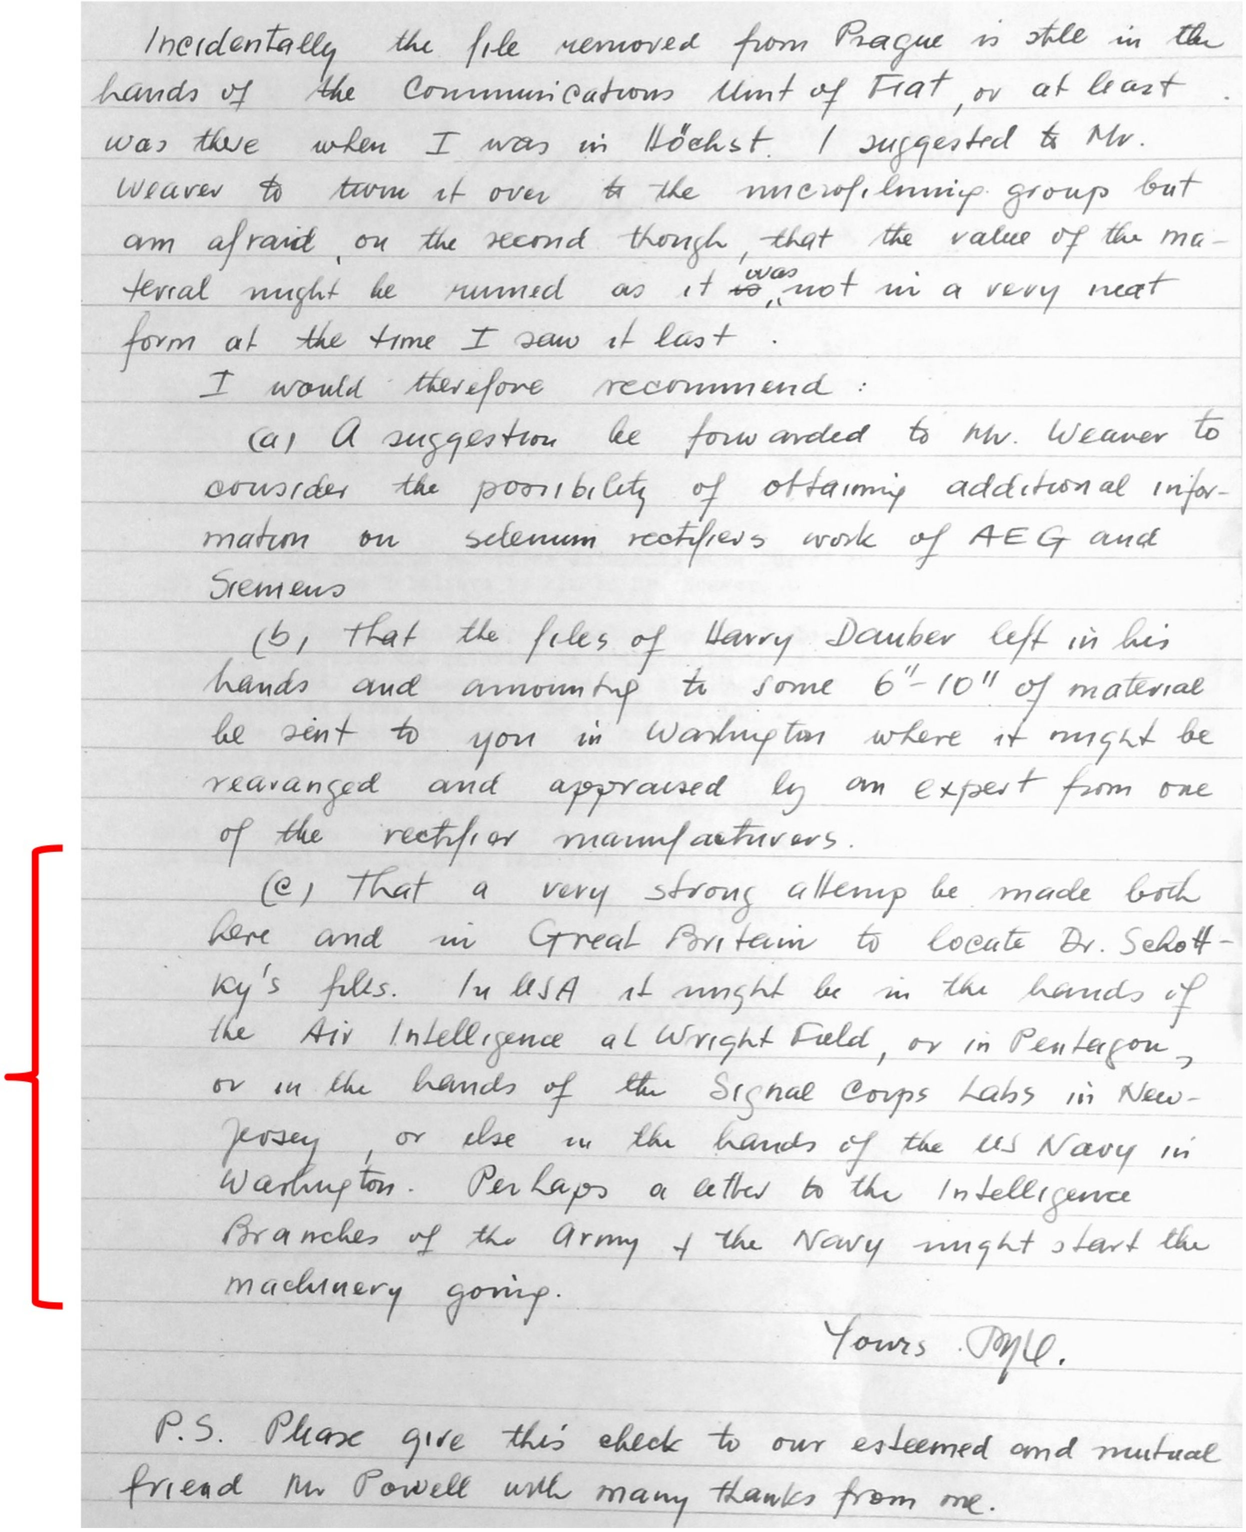
NARA RG 40, Entry UD-75, Box 24,
Folder Selenium Rectifier Machinery



Incidentally the file removed from Prague is still in the hands of the Communications Unit of Fiat, or at least was there when I was in Höchst. I suggested to Mr. Weaver to turn it over to the microfilming group but am afraid, on the second thought, that the value of the material might be ruined as it ~~is~~ was not in a very neat form at the time I saw it last.

I would therefore recommend:

(a) a suggestion be forwarded to Mr. Weaver to consider the possibility of obtaining additional information on selenium rectifiers work of AEG and Siemens

(b) that the files of Harry Dauber left in his hands and amounting to some 6"-10" of material be sent to you in Washington where it might be rearanged and appraised by an expert from one of the rectifier manufacturers.

(c) That a very strong attemp be made both here and in Great Britain to locate Dr. Schottky's files. In USA it might be in the hands of the Air Intelligence at Wright Field, or in Pentagon, or in the hands of the Signal Corps Labs in New-Jersey, or else in the hands of the US Navy in Washington. Perhaps a letter to the Intelligence Branches of the Army + the Navy might start the machinery going.

Yours

P.S. Please give this check to our esteemed and mutual friend Mr Powell with many thanks from me.

Patentansprüche:

1. Halbleiteranordnung mit einem Halbleiterkristall, der mit zwei stromführenden Elektroden kontaktiert und außerdem mit einer Steuerelektrode versehen ist, welche den zwischen den beiden stromführenden Elektroden im Halbleiterkristall im wesentlichen parallel zur Fläche der Steuerelektrode fließenden elektrischen Strom kapazitiv steuert, **dadurch gekennzeichnet,** daß zwischen dem stromführenden Halbleiterkristall und der ebenfalls als Halbleiterkristall ausgebildeten Steuerelektrode eine elektronische Sperrschicht (Verarmungsrandschicht) erzeugt ist.

2. Halbleiteranordnung nach Anspruch 1, dadurch gekennzeichnet, daß die Kristallite der Halbleiterkörper so groß sind, daß eine etwaige weitere Auskristallisation den Widerstand des gesamten Halbleiters nicht mehr verändert.

3. Halbleiteranordnung nach Anspruch 1 oder 2, dadurch gekennzeichnet, daß ein elektronenleitender Halbleiterkristall durch einen defektelektronenleitenden Halbleiterkristall gesteuert ist.

4. Halbleiteranordnung nach Anspruch 1 oder 2, dadurch gekennzeichnet, daß ein defektelektronenleitender Halbleiterkristall durch einen elektronenleitenden Halbleiterkristall gesteuert ist.

5. Halbleiteranordnung nach einem der Ansprüche 1 bis 4, dadurch gekennzeichnet, daß zusätzlich zu dem äußeren Feld der Steuerelektrode noch innere Felder vorgesehen sind, die von geordneten atomaren oder molekularen Schichten ausgehen.

6. Halbleiteranordnung nach einem der Ansprüche 1 bis 5, dadurch gekennzeichnet, daß die Halbleiter aus Silicium oder Germanium bestehen.

7. Halbleiteranordnung nach einem der Ansprüche 1 bis 6, dadurch gekennzeichnet, daß die Halbleiter aus CU_2O, Se, PbS oder ZnS bestehen.

8. Halbleiteranordnung nach einem der Ansprüche 1 bis 7, dadurch gekennzeichnet, daß an der Steuerelektrode ein Spannungsabfall aufrechterhalten ist.

9. Halbleiteranordnung nach einem der Ansprüche 1 bis 8, dadurch gekennzeichnet, daß die Stromelektroden auf die Halbleiterkristalle sperrschichtfrei aufgebracht sind.

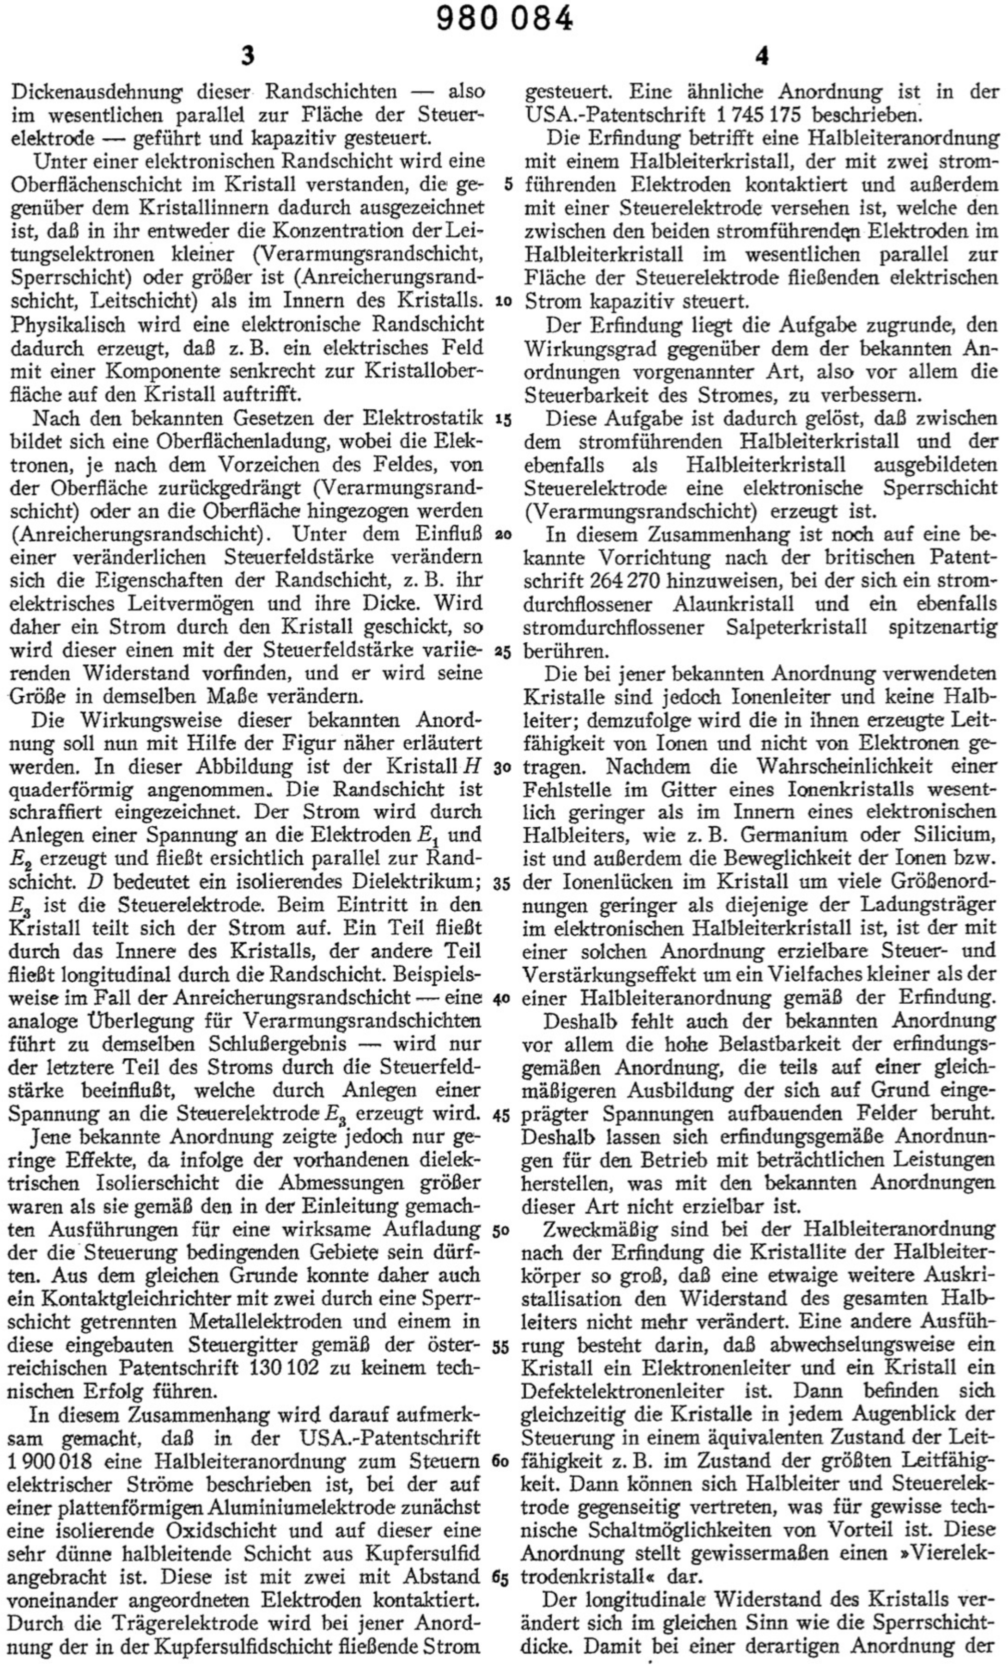
10. Halbleiteranordnung nach einem der Ansprüche 1 bis 9, dadurch gekennzeichnet, daß der stromführende Halbleiterkristall auf eine elektrisch isolierende Trägerplatte möglichst hoher Wärmeleitfähigkeit aufgebracht ist.

Bei Untersuchungen über die Wanderung von Farbzentren in einem Alkalihalogenidkristall, die von R. W. Pohl in den Nachr. von der Ges. d. Wiss. zu Göttingen, Jahresber. 1933/34, S. 55, beschrieben sind, ist der Gedanke geäußert worden, die Elektronenröhren in den Rundfunkgeräten durch kleine Kristalle zu ersetzen. Zu einem modellmäßigen Versuch über die Steuerung von Elektronen in Kristallen kam es jedoch erst mehrere Jahre später, als man die Bedeutung der Sperrschichten für die Gleichrichtung erkannt hatte. Es ist damals vorgeschlagen worden, in die Sperrschicht eines Alkalihalogenidkristalls ein Steuergitter einzubauen; vgl. hierzu R. Hilsch und R. W. Pohl, Z.S.Phys., 111, 399, 1938. Die Sperrschicht ist hier der glasklare, an eine Elektrode grenzende Teil des sonst mit Farbzentren erfüllten Kristalls. Sie ist bei diesen Versuchen von makroskopischen Abmessungen, und der zu steuernde Strom durchfließt dabei die Sperrschicht senkrecht, oder genauer gesagt, er fließt im wesentlichen parallel zur Dickenausdehnung der Sperrschicht. Im allgemeinen ist die Trägheit der mit Alkalihalogenidkristallen arbeitenden Anordnung ungeheuer groß, und ein stationärer Zustand stellt sich überhaupt nicht ein. Aus diesen Gründen haben die genannten Versuche nicht zu einem technisch brauchbaren Gleichrichter oder gar Verstärker geführt.

Ganz anders liegen die Verhältnisse bei den technischen Gleichrichtern (Selen- u. Kupferoxydulgleichrichter, Spitzendetektor). Die hier auftretenden Sperrschichten sind nicht wie die glasklaren Sperrschichten bei den Alkalihalogenidkristallen elektrisch neutral, sondern besitzen eine merkliche, mit der äußeren elektrischen Spannung veränderliche elektrische Raumladung. Zur Erläuterung des Sachverhaltes wird festgestellt, daß bei obigen Versuchen außer den beweglichen Elektronen (gewöhnliche Elektronen oder die neuerdings viel diskutierten Defektelektronen) gleichzeitig auch bewegliche Ionen vorhanden sind. Eine Sperrschicht entsteht in diesem Falle dadurch, daß sowohl die Elektronen als auch die Ionen aus dem fraglichen Gebiet herauswandern. Die Bewegung erfolgt so, daß nirgends ein Überschuß an Ladung auftritt; es treten daher auch keine rücktreibenden Kräfte auf; die Dicke der Sperrschicht kann daher unbegrenzt wachsen. Bei den technischen Gleichrichtern hingegen ist die Ionenbeweglichkeit vernachlässigbar klein. Das Herauswandern der Elektronen aus einem Randgebiet führt notwendig zur elektrischen Aufladung dieses Gebietes. Die dabei auftretenden rücktreibenden Kräfte verhindern, daß die Sperrschichten beliebig dick werden. Neuerdings, vergleiche hierzu W. Schottky: Über Sperrschichten, Schweizer Archiv, 1941, Heft 1 und 3, insbesondere S. 29 oben rechts und Anmerkung 13, hat man die Dicke dieser Sperrschichten, die wir zur Unterscheidung von den Sperrschichten bei Alkalihalogenidkristallen elektronische Sperrschichten nennen wollen, zu 10^{-5} cm abgeschätzt und auch aufgeklärt, weshalb gerade bei den technisch brauchbaren Kristallgleichrichtern der Einbau eines Steuergitters in die Sperrschicht und damit der Bau eines Kristallverstärkers auf rein elektronischer Grundlage unmöglich ist.

Heil beschreibt in der britischen Patentschrift 439 457 eine Anordnung, bei der die nach dem geschilderten Stand der Technik sich darbietenden Schwierigkeiten teilweise vermieden werden. Bei dieser bekannten Anordnung werden in Kristallen unter der Wirkung eines elektrischen Steuerfeldes elektronische Randschichten erzeugt und verändert, und der zu steuernde Strom wird senkrecht zur

Figure B.52: Heinrich Welker and Herbert Mataré began developing a point-contact transistor in Germany during the war, filed a detailed patent application based on that wartime work on 6 April 1945, and publicly announced their transistor in 1948 in France.



980 084

3

Dickenausdehnung dieser Randschichten — also im wesentlichen parallel zur Fläche der Steuerelektrode — geführt und kapazitiv gesteuert.

Unter einer elektronischen Randschicht wird eine Oberflächenschicht im Kristall verstanden, die gegenüber dem Kristallinnern dadurch ausgezeichnet ist, daß in ihr entweder die Konzentration der Leitungselektronen kleiner (Verarmungsrandschicht, Sperrschicht) oder größer ist (Anreicherungsrandschicht, Leitschicht) als im Innern des Kristalls. Physikalisch wird eine elektronische Randschicht dadurch erzeugt, daß z. B. ein elektrisches Feld mit einer Komponente senkrecht zur Kristalloberfläche auf den Kristall auftrifft.

Nach den bekannten Gesetzen der Elektrostatik bildet sich eine Oberflächenladung, wobei die Elektronen, je nach dem Vorzeichen des Feldes, von der Oberfläche zurückgedrängt (Verarmungsrandschicht) oder an die Oberfläche hingezogen werden (Anreicherungsrandschicht). Unter dem Einfluß einer veränderlichen Steuerfeldstärke verändern sich die Eigenschaften der Randschicht, z. B. ihr elektrisches Leitvermögen und ihre Dicke. Wird daher ein Strom durch den Kristall geschickt, so wird dieser einen mit der Steuerfeldstärke variierenden Widerstand vorfinden, und er wird seine Größe in demselben Maße verändern.

Die Wirkungsweise dieser bekannten Anordnung soll nun mit Hilfe der Figur näher erläutert werden. In dieser Abbildung ist der Kristall *H* quaderförmig angenommen. Die Randschicht ist schraffiert eingezeichnet. Der Strom wird durch Anlegen einer Spannung an die Elektroden E_1 und E_2 erzeugt und fließt ersichtlich parallel zur Randschicht. *D* bedeutet ein isolierendes Dielektrikum; E_3 ist die Steuerelektrode. Beim Eintritt in den Kristall teilt sich der Strom auf. Ein Teil fließt durch das Innere des Kristalls, der andere Teil fließt longitudinal durch die Randschicht. Beispielsweise im Fall der Anreicherungsrandschicht — eine analoge Überlegung für Verarmungsrandschichten führt zu demselben Schlußergebnis — wird nur der letztere Teil des Stroms durch die Steuerfeldstärke beeinflußt, welche durch Anlegen einer Spannung an die Steuerelektrode E_3 erzeugt wird.

Jene bekannte Anordnung zeigte jedoch nur geringe Effekte, da infolge der vorhandenen dielektrischen Isolierschicht die Abmessungen größer waren als sie gemäß den in der Einleitung gemachten Ausführungen für eine wirksame Aufladung der die Steuerung bedingenden Gebiete sein dürften. Aus dem gleichen Grunde konnte daher auch ein Kontaktgleichrichter mit zwei durch eine Sperrschicht getrennten Metallelektroden und einem in diese eingebauten Steuergitter gemäß der österreichischen Patentschrift 130 102 zu keinem technischen Erfolg führen.

In diesem Zusammenhang wird darauf aufmerksam gemacht, daß in der USA.-Patentschrift 1 900 018 eine Halbleiteranordnung zum Steuern elektrischer Ströme beschrieben ist, bei der auf einer plattenförmigen Aluminiumelektrode zunächst eine isolierende Oxidschicht und auf dieser eine sehr dünne halbleitende Schicht aus Kupfersulfid angebracht ist. Diese ist mit zwei mit Abstand voneinander angeordneten Elektroden kontaktiert. Durch die Trägerelektrode wird bei jener Anordnung der in der Kupfersulfidschicht fließende Strom gesteuert. Eine ähnliche Anordnung ist in der USA.-Patentschrift 1 745 175 beschrieben.

4

Die Erfindung betrifft eine Halbleiteranordnung mit einem Halbleiterkristall, der mit zwei stromführenden Elektroden kontaktiert und außerdem mit einer Steuerelektrode versehen ist, welche den zwischen den beiden stromführenden Elektroden im Halbleiterkristall im wesentlichen parallel zur Fläche der Steuerelektrode fließenden elektrischen Strom kapazitiv steuert.

Der Erfindung liegt die Aufgabe zugrunde, den Wirkungsgrad gegenüber dem der bekannten Anordnungen vorgenannter Art, also vor allem die Steuerbarkeit des Stromes, zu verbessern.

Diese Aufgabe ist dadurch gelöst, daß zwischen dem stromführenden Halbleiterkristall und der ebenfalls als Halbleiterkristall ausgebildeten Steuerelektrode eine elektronische Sperrschicht (Verarmungsrandschicht) erzeugt ist.

In diesem Zusammenhang ist noch auf eine bekannte Vorrichtung nach der britischen Patentschrift 264 270 hinzuweisen, bei der sich ein stromdurchflossener Alaunkristall und ein ebenfalls stromdurchflossener Salpeterkristall spitzenartig berühren.

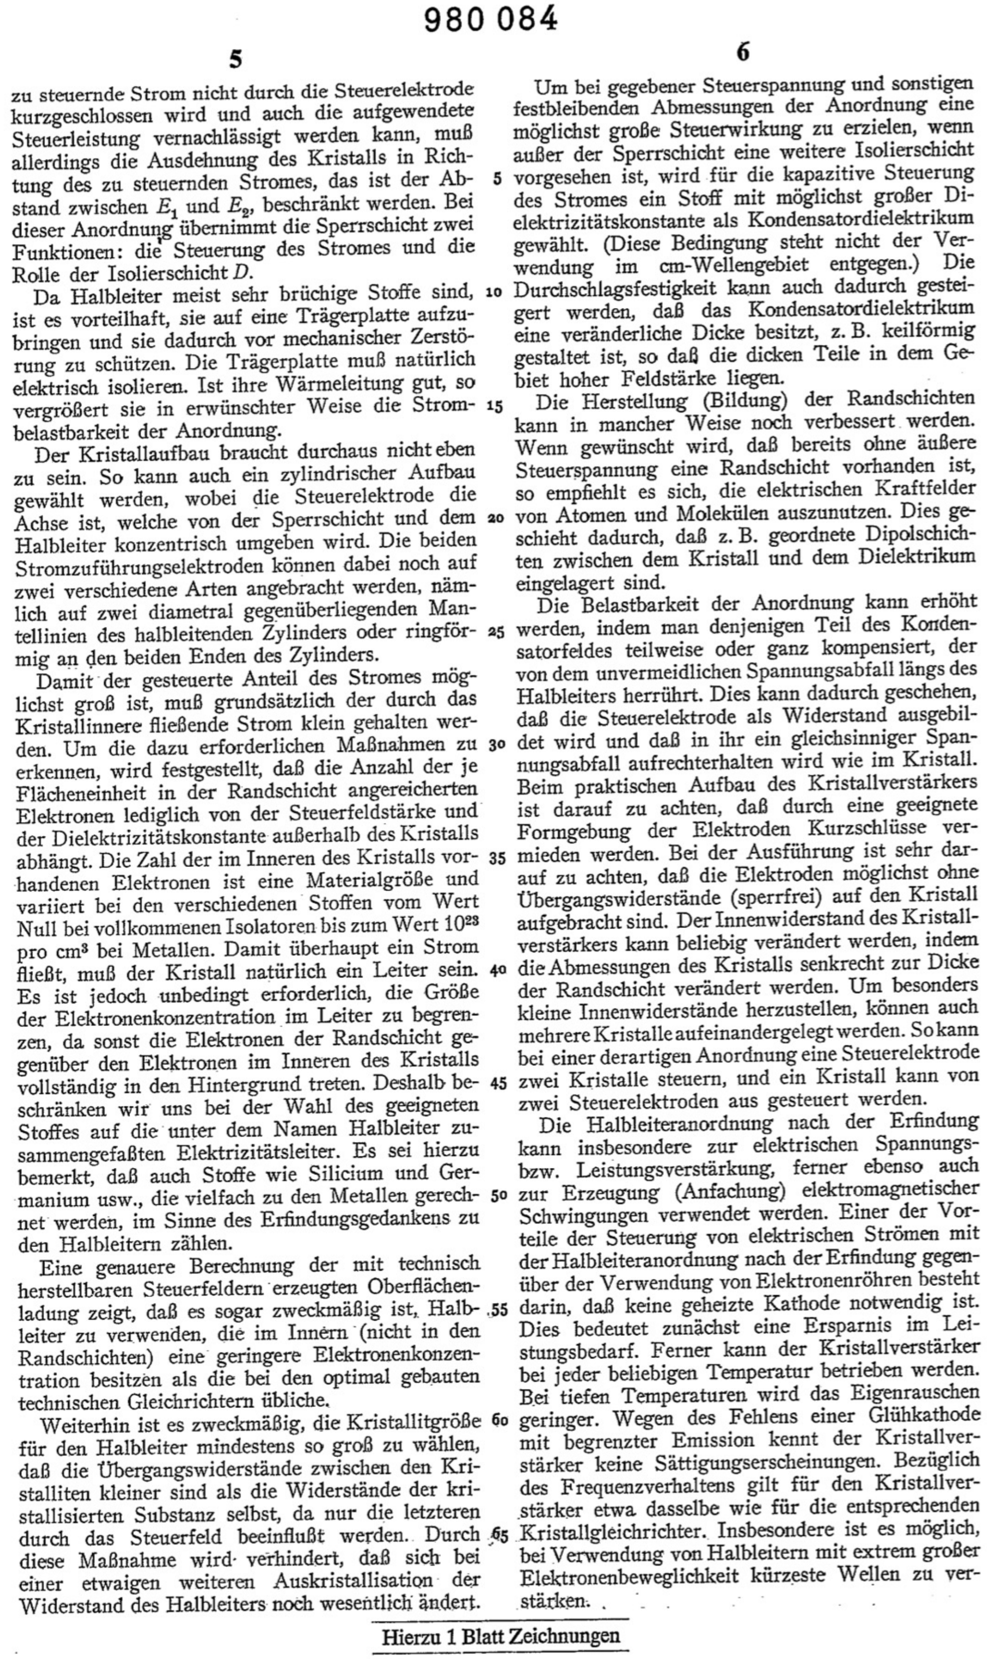
Die bei jener bekannten Anordnung verwendeten Kristalle sind jedoch Ionenleiter und keine Halbleiter; demzufolge wird die in ihnen erzeugte Leitfähigkeit von Ionen und nicht von Elektronen getragen. Nachdem die Wahrscheinlichkeit einer Fehlstelle im Gitter eines Ionenkristalls wesentlich geringer als im Innern eines elektronischen Halbleiters, wie z. B. Germanium oder Silicium, ist und außerdem die Beweglichkeit der Ionen bzw. der Ionenlücken im Kristall um viele Größenordnungen geringer als diejenige der Ladungsträger im elektronischen Halbleiterkristall ist, ist der mit einer solchen Anordnung erzielbare Steuer- und Verstärkungseffekt um ein Vielfaches kleiner als der einer Halbleiteranordnung gemäß der Erfindung.

Deshalb fehlt auch der bekannten Anordnung vor allem die hohe Belastbarkeit der erfindungsgemäßen Anordnung, die teils auf einer gleichmäßigeren Ausbildung der sich auf Grund eingeprägter Spannungen aufbauenden Felder beruht. Deshalb lassen sich erfindungsgemäße Anordnungen für den Betrieb mit beträchtlichen Leistungen herstellen, was mit den bekannten Anordnungen dieser Art nicht erzielbar ist.

Zweckmäßig sind bei der Halbleiteranordnung nach der Erfindung die Kristallite der Halbleiterkörper so groß, daß eine etwaige weitere Auskristallisation den Widerstand des gesamten Halbleiters nicht mehr verändert. Eine andere Ausführung besteht darin, daß abwechselungsweise ein Kristall ein Elektronenleiter und ein Kristall ein Defektelektronenleiter ist. Dann befinden sich gleichzeitig die Kristalle in jedem Augenblick der Steuerung in einem äquivalenten Zustand der Leitfähigkeit z. B. im Zustand der größten Leitfähigkeit. Dann können sich Halbleiter und Steuerelektrode gegenseitig vertreten, was für gewisse technische Schaltmöglichkeiten von Vorteil ist. Diese Anordnung stellt gewissermaßen einen »Vierelektrodenkristall« dar.

Der longitudinale Widerstand des Kristalls verändert sich im gleichen Sinn wie die Sperrschichtdicke. Damit bei einer derartigen Anordnung der

Figure B.53: Heinrich Welker and Herbert Mataré began developing a point-contact transistor in Germany during the war, filed a detailed patent application based on that wartime work on 6 April 1945, and publicly announced their transistor in 1948 in France.



980 084

5

zu steuernde Strom nicht durch die Steuerelektrode kurzgeschlossen wird und auch die aufgewendete Steuerleistung vernachlässigt werden kann, muß allerdings die Ausdehnung des Kristalls in Richtung des zu steuernden Stromes, das ist der Abstand zwischen E_1 und E_2, beschränkt werden. Bei dieser Anordnung übernimmt die Sperrschicht zwei Funktionen: die Steuerung des Stromes und die Rolle der Isolierschicht *D*.

Da Halbleiter meist sehr brüchige Stoffe sind, ist es vorteilhaft, sie auf eine Trägerplatte aufzubringen und sie dadurch vor mechanischer Zerstörung zu schützen. Die Trägerplatte muß natürlich elektrisch isolieren. Ist ihre Wärmeleitung gut, so vergrößert sie in erwünschter Weise die Strombelastbarkeit der Anordnung.

Der Kristallaufbau braucht durchaus nicht eben zu sein. So kann auch ein zylindrischer Aufbau gewählt werden, wobei die Steuerelektrode die Achse ist, welche von der Sperrschicht und dem Halbleiter konzentrisch umgeben wird. Die beiden Stromzuführungselektroden können dabei noch auf zwei verschiedene Arten angebracht werden, nämlich auf zwei diametral gegenüberliegenden Mantellinien des halbleitenden Zylinders oder ringförmig an den beiden Enden des Zylinders.

Damit der gesteuerte Anteil des Stromes möglichst groß ist, muß grundsätzlich der durch das Kristallinnere fließende Strom klein gehalten werden. Um die dazu erforderlichen Maßnahmen zu erkennen, wird festgestellt, daß die Anzahl der je Flächeneinheit in der Randschicht angereicherten Elektronen lediglich von der Steuerfeldstärke und der Dielektrizitätskonstante außerhalb des Kristalls abhängt. Die Zahl der im Inneren des Kristalls vorhandenen Elektronen ist eine Materialgröße und variiert bei den verschiedenen Stoffen vom Wert Null bei vollkommenen Isolatoren bis zum Wert 10^{23} pro cm^3 bei Metallen. Damit überhaupt ein Strom fließt, muß der Kristall natürlich ein Leiter sein. Es ist jedoch unbedingt erforderlich, die Größe der Elektronenkonzentration im Leiter zu begrenzen, da sonst die Elektronen der Randschicht gegenüber den Elektronen im Inneren des Kristalls vollständig in den Hintergrund treten. Deshalb beschränken wir uns bei der Wahl des geeigneten Stoffes auf die unter dem Namen Halbleiter zusammengefaßten Elektrizitätsleiter. Es sei hierzu bemerkt, daß auch Stoffe wie Silicium und Germanium usw., die vielfach zu den Metallen gerechnet werden, im Sinne des Erfindungsgedankens zu den Halbleitern zählen.

Eine genauere Berechnung der mit technisch herstellbaren Steuerfeldern erzeugten Oberflächenladung zeigt, daß es sogar zweckmäßig ist, Halbleiter zu verwenden, die im Innern (nicht in den Randschichten) eine geringere Elektronenkonzentration besitzen als die bei den optimal gebauten technischen Gleichrichtern übliche.

Weiterhin ist es zweckmäßig, die Kristallitgröße für den Halbleiter mindestens so groß zu wählen, daß die Übergangswiderstände zwischen den Kristalliten kleiner sind als die Widerstände der kristallisierten Substanz selbst, da nur die letzteren durch das Steuerfeld beeinflußt werden. Durch diese Maßnahme wird verhindert, daß sich bei einer etwaigen weiteren Auskristallisation der Widerstand des Halbleiters noch wesentlich ändert.

6

Um bei gegebener Steuerspannung und sonstigen festbleibenden Abmessungen der Anordnung eine möglichst große Steuerwirkung zu erzielen, wenn außer der Sperrschicht eine weitere Isolierschicht vorgesehen ist, wird für die kapazitive Steuerung des Stromes ein Stoff mit möglichst großer Dielektrizitätskonstante als Kondensatordielektrikum gewählt. (Diese Bedingung steht nicht der Verwendung im cm-Wellengebiet entgegen.) Die Durchschlagsfestigkeit kann auch dadurch gesteigert werden, daß das Kondensatordielektrikum eine veränderliche Dicke besitzt, z. B. keilförmig gestaltet ist, so daß die dicken Teile in dem Gebiet hoher Feldstärke liegen.

Die Herstellung (Bildung) der Randschichten kann in mancher Weise noch verbessert werden. Wenn gewünscht wird, daß bereits ohne äußere Steuerspannung eine Randschicht vorhanden ist, so empfiehlt es sich, die elektrischen Kraftfelder von Atomen und Molekülen auszunutzen. Dies geschieht dadurch, daß z. B. geordnete Dipolschichten zwischen dem Kristall und dem Dielektrikum eingelagert sind.

Die Belastbarkeit der Anordnung kann erhöht werden, indem man denjenigen Teil des Kondensatorfeldes teilweise oder ganz kompensiert, der von dem unvermeidlichen Spannungsabfall längs des Halbleiters herrührt. Dies kann dadurch geschehen, daß die Steuerelektrode als Widerstand ausgebildet wird und daß in ihr ein gleichsinniger Spannungsabfall aufrechterhalten wird wie im Kristall. Beim praktischen Aufbau des Kristallverstärkers ist darauf zu achten, daß durch eine geeignete Formgebung der Elektroden Kurzschlüsse vermieden werden. Bei der Ausführung ist sehr darauf zu achten, daß die Elektroden möglichst ohne Übergangswiderstände (sperrfrei) auf den Kristall aufgebracht sind. Der Innenwiderstand des Kristallverstärkers kann beliebig verändert werden, indem die Abmessungen des Kristalls senkrecht zur Dicke der Randschicht verändert werden. Um besonders kleine Innenwiderstände herzustellen, können auch mehrere Kristalle aufeinandergelegt werden. So kann bei einer derartigen Anordnung eine Steuerelektrode zwei Kristalle steuern, und ein Kristall kann von zwei Steuerelektroden aus gesteuert werden.

Die Halbleiteranordnung nach der Erfindung kann insbesondere zur elektrischen Spannungs- bzw. Leistungsverstärkung, ferner ebenso auch zur Erzeugung (Anfachung) elektromagnetischer Schwingungen verwendet werden. Einer der Vorteile der Steuerung von elektrischen Strömen mit der Halbleiteranordnung nach der Erfindung gegenüber der Verwendung von Elektronenröhren besteht darin, daß keine geheizte Kathode notwendig ist. Dies bedeutet zunächst eine Ersparnis im Leistungsbedarf. Ferner kann der Kristallverstärker bei jeder beliebigen Temperatur betrieben werden. Bei tiefen Temperaturen wird das Eigenrauschen geringer. Wegen des Fehlens einer Glühkathode mit begrenzter Emission kennt der Kristallverstärker keine Sättigungserscheinungen. Bezüglich des Frequenzverhaltens gilt für den Kristallverstärker etwa dasselbe wie für die entsprechenden Kristallgleichrichter. Insbesondere ist es möglich, bei Verwendung von Halbleitern mit extrem großer Elektronenbeweglichkeit kürzeste Wellen zu verstärken.

UNITED STATES PATENT OFFICE

2,673,948

CRYSTAL DEVICE FOR CONTROLLING ELECTRIC CURRENTS BY MEANS OF A SOLID SEMICONDUCTOR

Herbert François Mataré and Heinrich Welker, Vaucresson, France, assignors to Societe Anonyme dite: Compagnie des Freins et Signaux Westinghouse, Paris, France

Application August 11, 1949, Serial No. 109,752

Claims priority, application France August 13, 1948

3 Claims. (Cl. 317—235)

1

This invention relates to crystal devices for controlling electric currents by means of a solid semiconductor with the use of one or more control electrodes, either in a barrier layer of the semiconductor (see for example patent of addition No. 38,744 of July 5, 1930, to French Patent No. 649,432 of January 28, 1928, and French Patent No. 866,372 of October 5, 1942), or closely adjacent to semiconductive layers with a suitable insulator interposed therebetween (see French Patent No. 786,454 of March 1, 1935).

However, such systems were so difficult to apply on a commercial scale that they had to be abandoned or development had to be restricted to simple experimental models or laboratory samples. This experience is supported by publications such as: Nachrichten der Gesellschaft der Wissenschaften zu Göttingen, Yearly Report, by R. W. Pohl, 1933/34, page 55; Schweizer Archive, 1941, volumes 1 and 3: Ueber Sperrschichten, by W. Schottky; Zeitschrift fur Physik, vol. 111, volumes 5 and 6, 1938 (R. Hilsch and R. W. Pohl); Modern Theory of Solids, 1940 (F. Seitz); Crystal Rectifiers, 1948 (H. C. Torrey and C. A. Whitmer).

In order practically to carry into effect systems comprising solid semiconductors arranged to produce electronic relay effects similar to those occurring in electronic tubes, two essential difficulties must be overcome. Firstly, the diameter of the contact area between metal needle and crystal should be of an order proportional to the thickness of the crystal barrier layer. Secondly, the gap between the conductive electrodes where engagement occurs with the semiconductor should be so selected that one of the conductive electrode point members will be positioned inside the barrier layer area of the other point member.

With the thickest barrier layer made hitherto, it would have been necessary to use values lower than 5 μ both for the diameters of the contact areas, on the one hand, and for the gap between the pair of point members, on the other hand. Now if the first requirement could be met, provided that a needle is applied to a crystal with a pressure lower than 0.33 oz., for example, the second requirement causes considerable mechanical difficulties.

Various attempts have been made to find workable arrangements comprising three-electrode semiconductors of microscopic dimensions. However, in order to obtain an appreciable control action, it is necessary to select a crystal of such a low electronic or non-electronic concentration,

2

or n-type excess and p-type deficiency concentration, respectively, that the inner resistivity of the device becomes very high. Arrangements of this type cannot be used practically for technical purposes.

The present invention permits to eliminate the above-mentioned difficulties and to realize on a commercial scale multi-electrode crystal devices of this kind for producing electronic relay action.

A more specific object of this invention is a multi-electrode device with at least two semiconductors of different conductivity characteristics; one of the semiconductors forms a control electrode and includes a surface barrier layer.

According to another feature of the invention, one of the semiconductors preferably the control electrode has a p-type (deficiency) or non-electronic conductivity and the other semiconductor an n-type (excess) or electronic conductivity.

According to a further feature of the invention, a semiconductor, preferably the other semiconductor mentioned above also includes a surface or internal barrier layer.

In one embodiment of the invention, the semiconductors or electrodes of the crystal are formed simultaneously from a single semiconductive element (such as germanium). In this element, by any suitable known method, zones of different conductivity characteristics are created.

Still in accordance with the invention, in at least one of said semiconductors or in one of the zones thereof such geometrical configuration is provided as to assure substantial radial distribution of the lines of force of the electric fields.

Furthermore, the invention relates to novel commercial products comprising multi-electrode crystal devices wherein external conductive electrodes are in direct contact with each semiconductive electrode, and wherein there is a gap between the contact points which is greater than 50 μ.

Other features and advantages of this invention will appear from the specification in connection with the accompanying drawings, which illustrate preferred embodiments of the invention in a diagrammatical fashion and by way of example only.

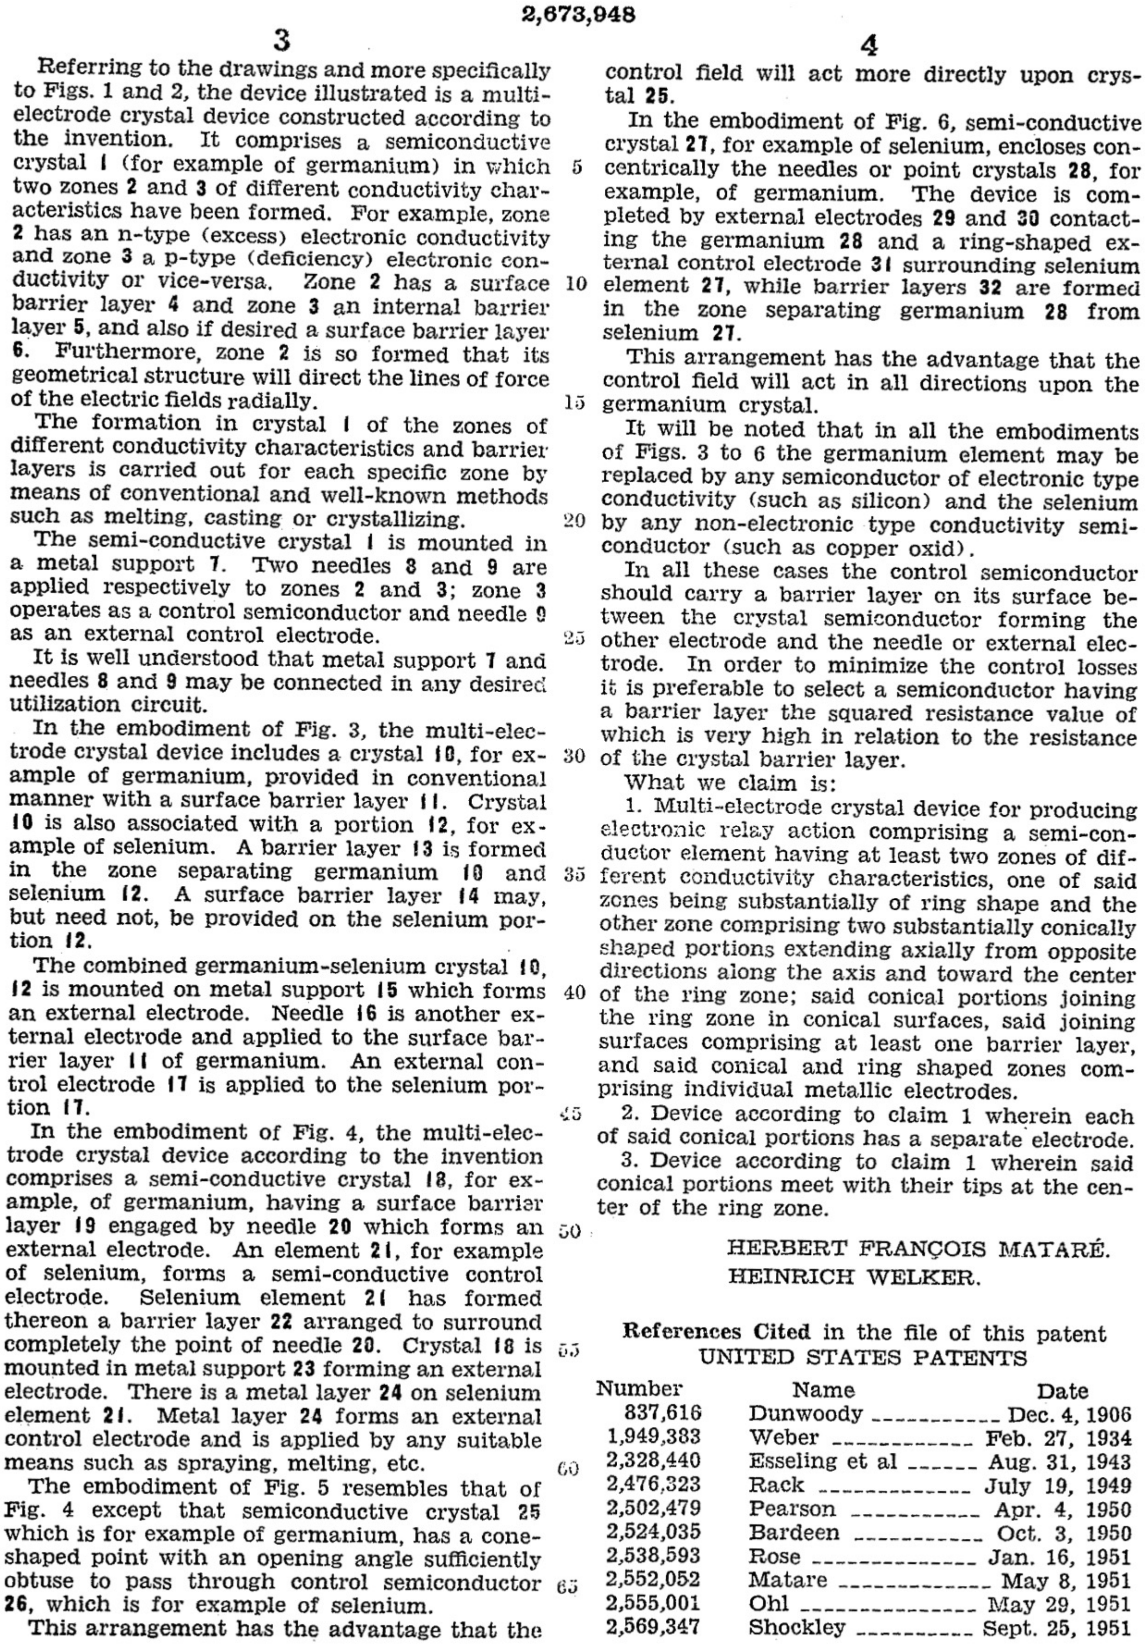
In the drawings:

Fig. 1 represents a cross section of a one embodiment,

Fig. 2 is a corresponding plan view, and

Figs. 3 to 6 represent cross-sections of other embodiments of the invention.

Figure B.58: Heinrich Welker and Herbert Mataré began developing a point-contact transistor in Germany during the war, filed a detailed patent application based on that wartime work on 6 April 1945, and publicly announced their transistor in 1948 in France.



2,673,948

3

Referring to the drawings and more specifically to Figs. 1 and 2, the device illustrated is a multi-electrode crystal device constructed according to the invention. It comprises a semiconductive crystal **1** (for example of germanium) in which two zones **2** and **3** of different conductivity characteristics have been formed. For example, zone **2** has an n-type (excess) electronic conductivity and zone **3** a p-type (deficiency) electronic conductivity or vice-versa. Zone **2** has a surface barrier layer **4** and zone **3** an internal barrier layer **5**, and also if desired a surface barrier layer **6**. Furthermore, zone **2** is so formed that its geometrical structure will direct the lines of force of the electric fields radially.

The formation in crystal **1** of the zones of different conductivity characteristics and barrier layers is carried out for each specific zone by means of conventional and well-known methods such as melting, casting or crystallizing.

The semi-conductive crystal **1** is mounted in a metal support **7**. Two needles **8** and **9** are applied respectively to zones **2** and **3**; zone **3** operates as a control semiconductor and needle **9** as an external control electrode.

It is well understood that metal support **7** and needles **8** and **9** may be connected in any desired utilization circuit.

In the embodiment of Fig. 3, the multi-electrode crystal device includes a crystal **10**, for example of germanium, provided in conventional manner with a surface barrier layer **11**. Crystal **10** is also associated with a portion **12**, for example of selenium. A barrier layer **13** is formed in the zone separating germanium **10** and selenium **12**. A surface barrier layer **14** may, but need not, be provided on the selenium portion **12**.

The combined germanium-selenium crystal **10**, **12** is mounted on metal support **15** which forms an external electrode. Needle **16** is another external electrode and applied to the surface barrier layer **11** of germanium. An external control electrode **17** is applied to the selenium portion **17**.

In the embodiment of Fig. 4, the multi-electrode crystal device according to the invention comprises a semi-conductive crystal **18**, for example, of germanium, having a surface barrier layer **19** engaged by needle **20** which forms an external electrode. An element **21**, for example of selenium, forms a semi-conductive control electrode. Selenium element **21** has formed thereon a barrier layer **22** arranged to surround completely the point of needle **20**. Crystal **18** is mounted in metal support **23** forming an external electrode. There is a metal layer **24** on selenium element **21**. Metal layer **24** forms an external control electrode and is applied by any suitable means such as spraying, melting, etc.

The embodiment of Fig. 5 resembles that of Fig. 4 except that semiconductive crystal **25** which is for example of germanium, has a cone-shaped point with an opening angle sufficiently obtuse to pass through control semiconductor **26**, which is for example of selenium.

This arrangement has the advantage that the

4

control field will act more directly upon crystal **25**.

In the embodiment of Fig. 6, semi-conductive crystal **27**, for example of selenium, encloses concentrically the needles or point crystals **28**, for example, of germanium. The device is completed by external electrodes **29** and **30** contacting the germanium **28** and a ring-shaped external control electrode **31** surrounding selenium element **27**, while barrier layers **32** are formed in the zone separating germanium **28** from selenium **27**.

This arrangement has the advantage that the control field will act in all directions upon the germanium crystal.

It will be noted that in all the embodiments of Figs. 3 to 6 the germanium element may be replaced by any semiconductor of electronic type conductivity (such as silicon) and the selenium by any non-electronic type conductivity semiconductor (such as copper oxid).

In all these cases the control semiconductor should carry a barrier layer on its surface between the crystal semiconductor forming the other electrode and the needle or external electrode. In order to minimize the control losses it is preferable to select a semiconductor having a barrier layer the squared resistance value of which is very high in relation to the resistance of the crystal barrier layer.

What we claim is:

1. Multi-electrode crystal device for producing electronic relay action comprising a semi-conductor element having at least two zones of different conductivity characteristics, one of said zones being substantially of ring shape and the other zone comprising two substantially conically shaped portions extending axially from opposite directions along the axis and toward the center of the ring zone; said conical portions joining the ring zone in conical surfaces, said joining surfaces comprising at least one barrier layer, and said conical and ring shaped zones comprising individual metallic electrodes.

2. Device according to claim 1 wherein each of said conical portions has a separate electrode.

3. Device according to claim 1 wherein said conical portions meet with their tips at the center of the ring zone.

HERBERT FRANÇOIS MATARÉ.
HEINRICH WELKER.

CIOS CONSOLIDATED ADVANCE FIELD TEAM
INVESTIGATION REPORT

TO: CIOS Secretariat.

1. Target No.

2.3. Laboratory of the Technical High School, Berlin, evacuated to Bad Liebenstein. Person interrogated: Dipl.Ing. Erwin Weise, formerly of Osram, now attached to this laboratory.

4. Interview only. Ovens and vacuum equipment for experimental work are in workable condition.

5. (1) Semi-conducting materials such as titanium-titanium dioxide resistors.
(11) Investigation of very thin films of titanium dioxide (TiO_2)
(111) Practical applications involving the use of these thin films:-
    a. Pyrometers.
    b. Gas pressure and flow devices.
    c. Rapid acting simulated pendulum.
(1V) Electrically controlled friction devices for control and amplification of mechanical forces.

6. Laboratory subject to guard regulations of 8th Corps Area. A book was just being written on the subject of semi-conductors by Mr. Weise, and it is desirable to obtain a copy when available.

7. Priority.

8. Mr. Weise spoke disparagingly of Dr. Pearson's published works on semi-conductors (Bell Laboratories). He was scheduled to lecture in America on this subject prior to the war at the request of Western Electrical Instrument Co., Irvington, NY. Claims to be a friend of Henry Behring of this company.

9. 5th June 1945.

10. Investigators: Mr. C.W. Hansell
Lt. Col. J.J. Slattery
Maj. J.M. Sanabria
Pfc. F. Koppl

11. Documents removed: "Uber ein Messgerat fur hohe und niedrige Gasdrucke mit Halbleiterwiderstanden" by Erwin Weise. Zeitschr.f. techn. Physik, No.4 1943, pages 66 to 69. No reports were available at the time but Mr. Weise stated that a manuscript of his should be produced within thirty days, and it is suggested that this matter be further investigated.

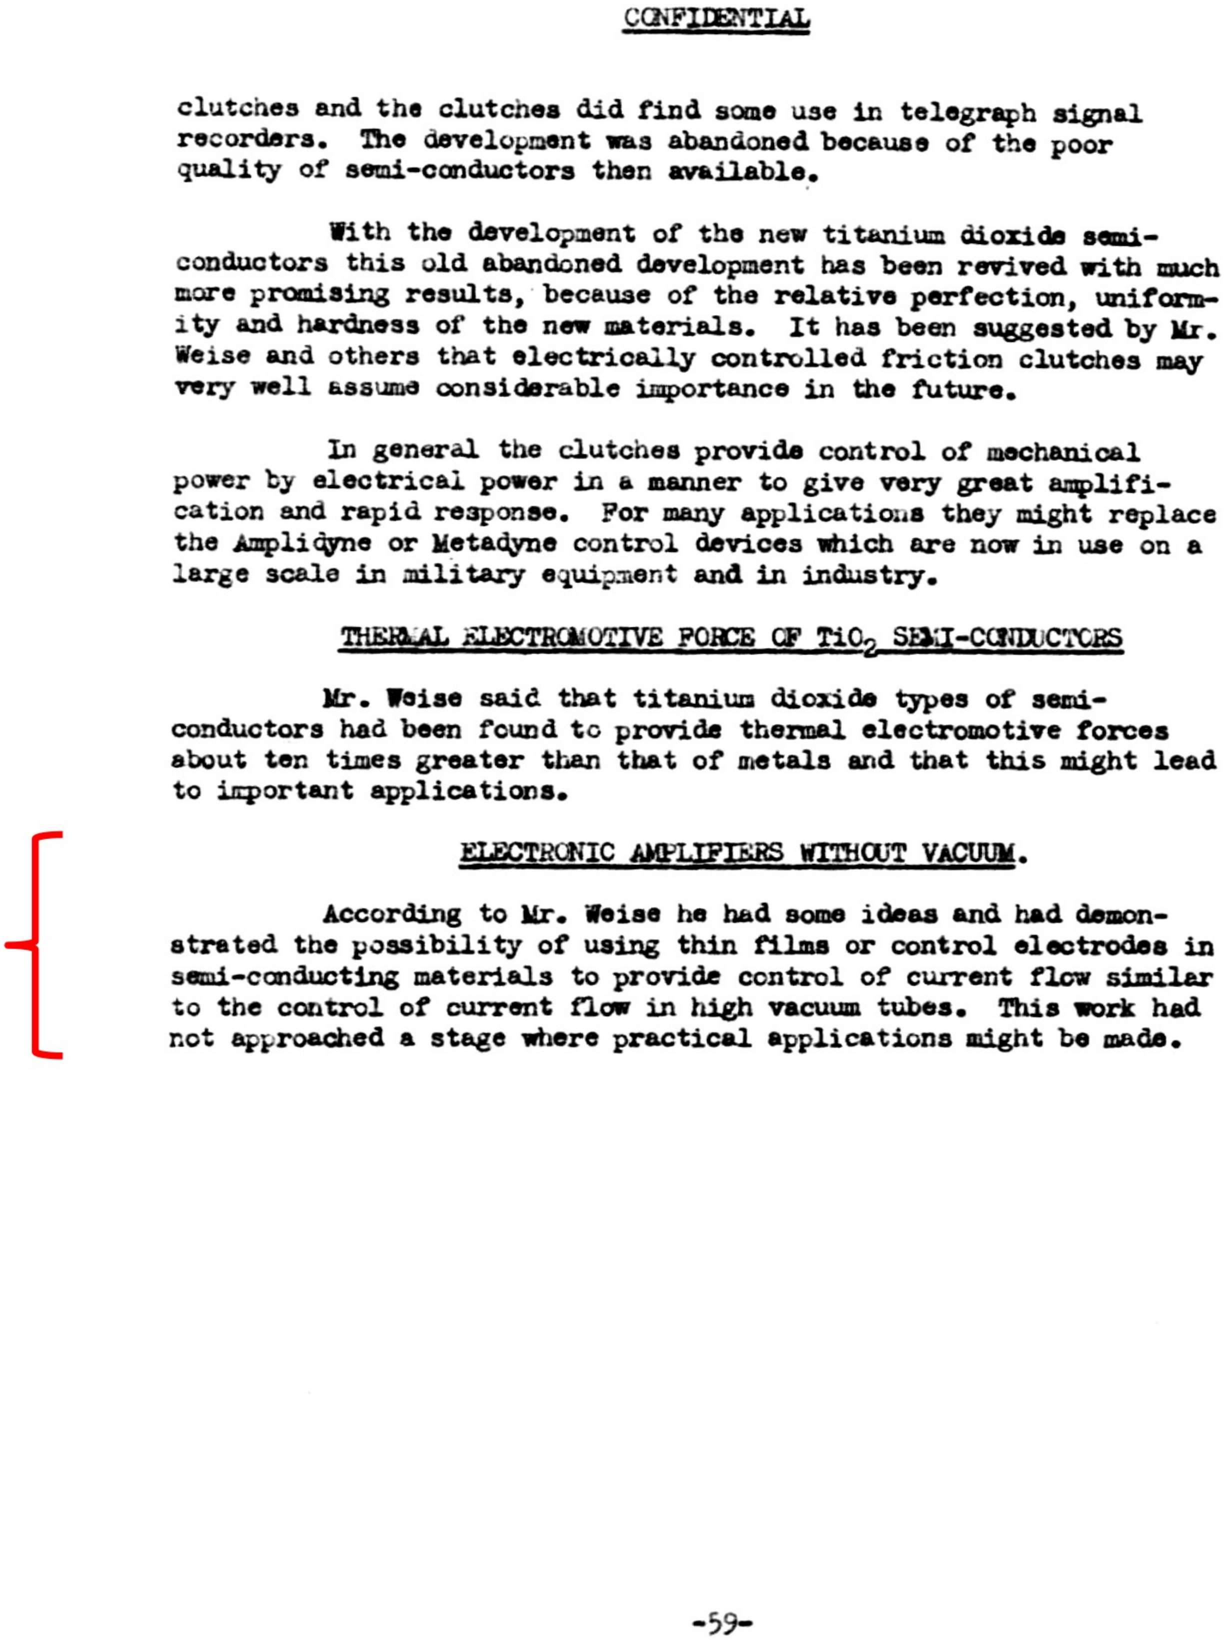
Figure B.61: Erwin Weise told Allied investigators that he "had demonstrated the possibility of using thin films or control electrodes in semi-conducting materials to provide control of current flow similar to the control of current flow in high vacuum tubes" to create "electronic amplifiers without vacuum."



CONFIDENTIAL

clutches and the clutches did find some use in telegraph signal recorders. The development was abandoned because of the poor quality of semi-conductors then available.

With the development of the new titanium dioxide semi-conductors this old abandoned development has been revived with much more promising results, because of the relative perfection, uniformity and hardness of the new materials. It has been suggested by Mr. Weise and others that electrically controlled friction clutches may very well assume considerable importance in the future.

In general the clutches provide control of mechanical power by electrical power in a manner to give very great amplification and rapid response. For many applications they might replace the Amplidyne or Metadyne control devices which are now in use on a large scale in military equipment and in industry.

THERMAL ELECTROMOTIVE FORCE OF TiO_2 SEMI-CONDUCTORS

Mr. Weise said that titanium dioxide types of semi-conductors had been found to provide thermal electromotive forces about ten times greater than that of metals and that this might lead to important applications.

ELECTRONIC AMPLIFIERS WITHOUT VACUUM.

According to Mr. Weise he had some ideas and had demonstrated the possibility of using thin films or control electrodes in semi-conducting materials to provide control of current flow similar to the control of current flow in high vacuum tubes. This work had not approached a stage where practical applications might be made.

Interrogation of:

Erwin Weise, Dipl. - Ing. (Director of the Semi-Conductivity
(Laboratory at Osram 1939 - 1945.
(Research work in the Rerhen Lab
(Technical High School Berlin
(evacuated to Bad Liebenstein
(1943 to end of hostilities.

Target No. C9/627.

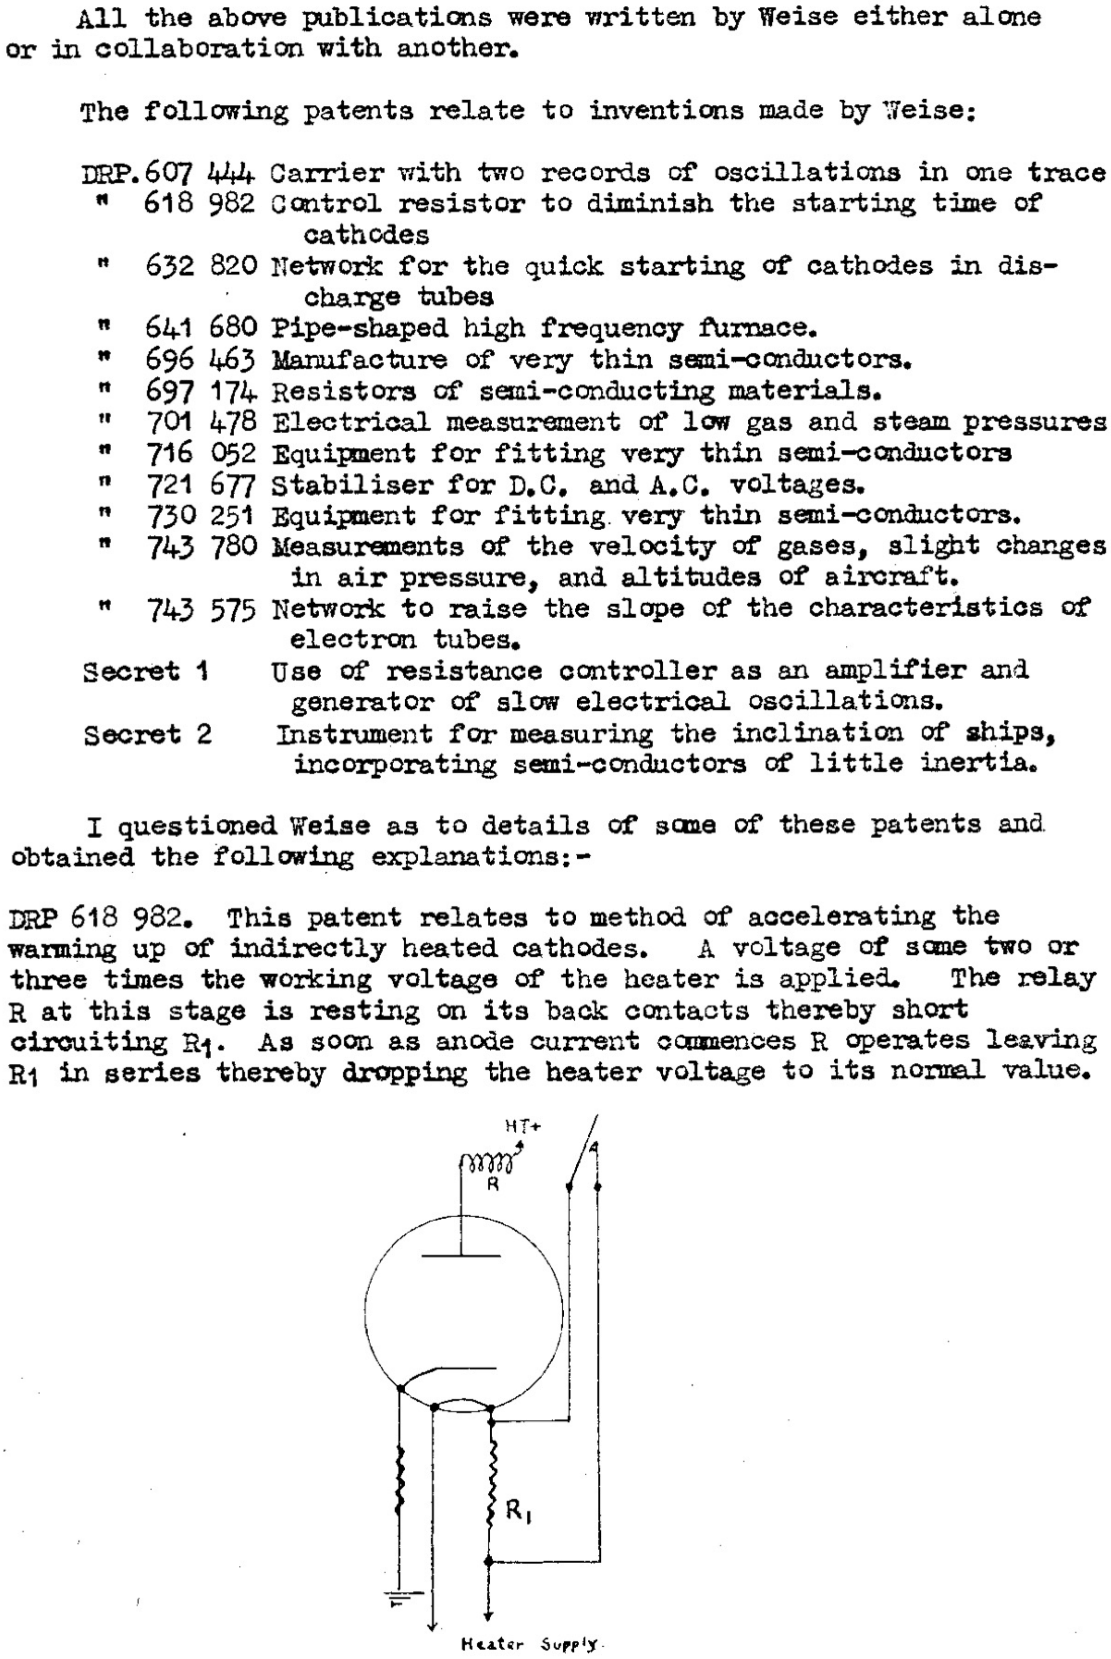
Interrogated by:- P. S. Brackenbury, Directorate of Instrument Production.

Main Interest: Research and Development of Semi-Conducting materials, practical applications for ultra-sensitive temperature measuring equipment and automatic control and stabilizing problems.

Semi-Conducting materials: The semi-conductors in which Weise had carried out research were in a material known as Magnesium Titanium Spinel ($MgO.TiO_2$) bearing the trade name of Urdox. This material is made in the form of sheet, rod and tube. The most common sizes being in rods or tubes about one centimetre long with a diameter of from one to two millimetres. It was also possible to make them in the form of fine filaments of about seventy microns diameter formed on a thread of silk of about thirty microns diameter. Attempts to make a finer filament than this were unsuccessful as the material tended to form into globules and so became discontinuous. It should be noted that the filaments are in reality very fine tubes with a wall thickness of about twenty microns, as the silk core is burnt away during processing. In the case of sheet it was not possible to go below a thickness of about ten microns.

The material has a negative temperature coefficient ranging from 0 to 10% per degree Centigrade with a time constant of as low as half a second for 90% of the total change. The temperature coefficient can be varied at will during manufacture by varying the TiO_2 content, higher proportions of TiO_2 give the greatest negative temperature coefficient. A mixture containing less than 10% TiO_2 fails to give the desired spinel crystal structure. The specific resistance ranges from 10 ohms/centimetre to 10^8 ohms/centimetre and is a function of the temperature and baking time during manufacture.

Figure B.64: Erwin Weise told Allied investigators that he “had demonstrated the possibility of using thin films or control electrodes in semi-conducting materials to provide control of current flow similar to the control of current flow in high vacuum tubes” to create “electronic amplifiers without vacuum.”



All the above publications were written by Weise either alone or in collaboration with another.

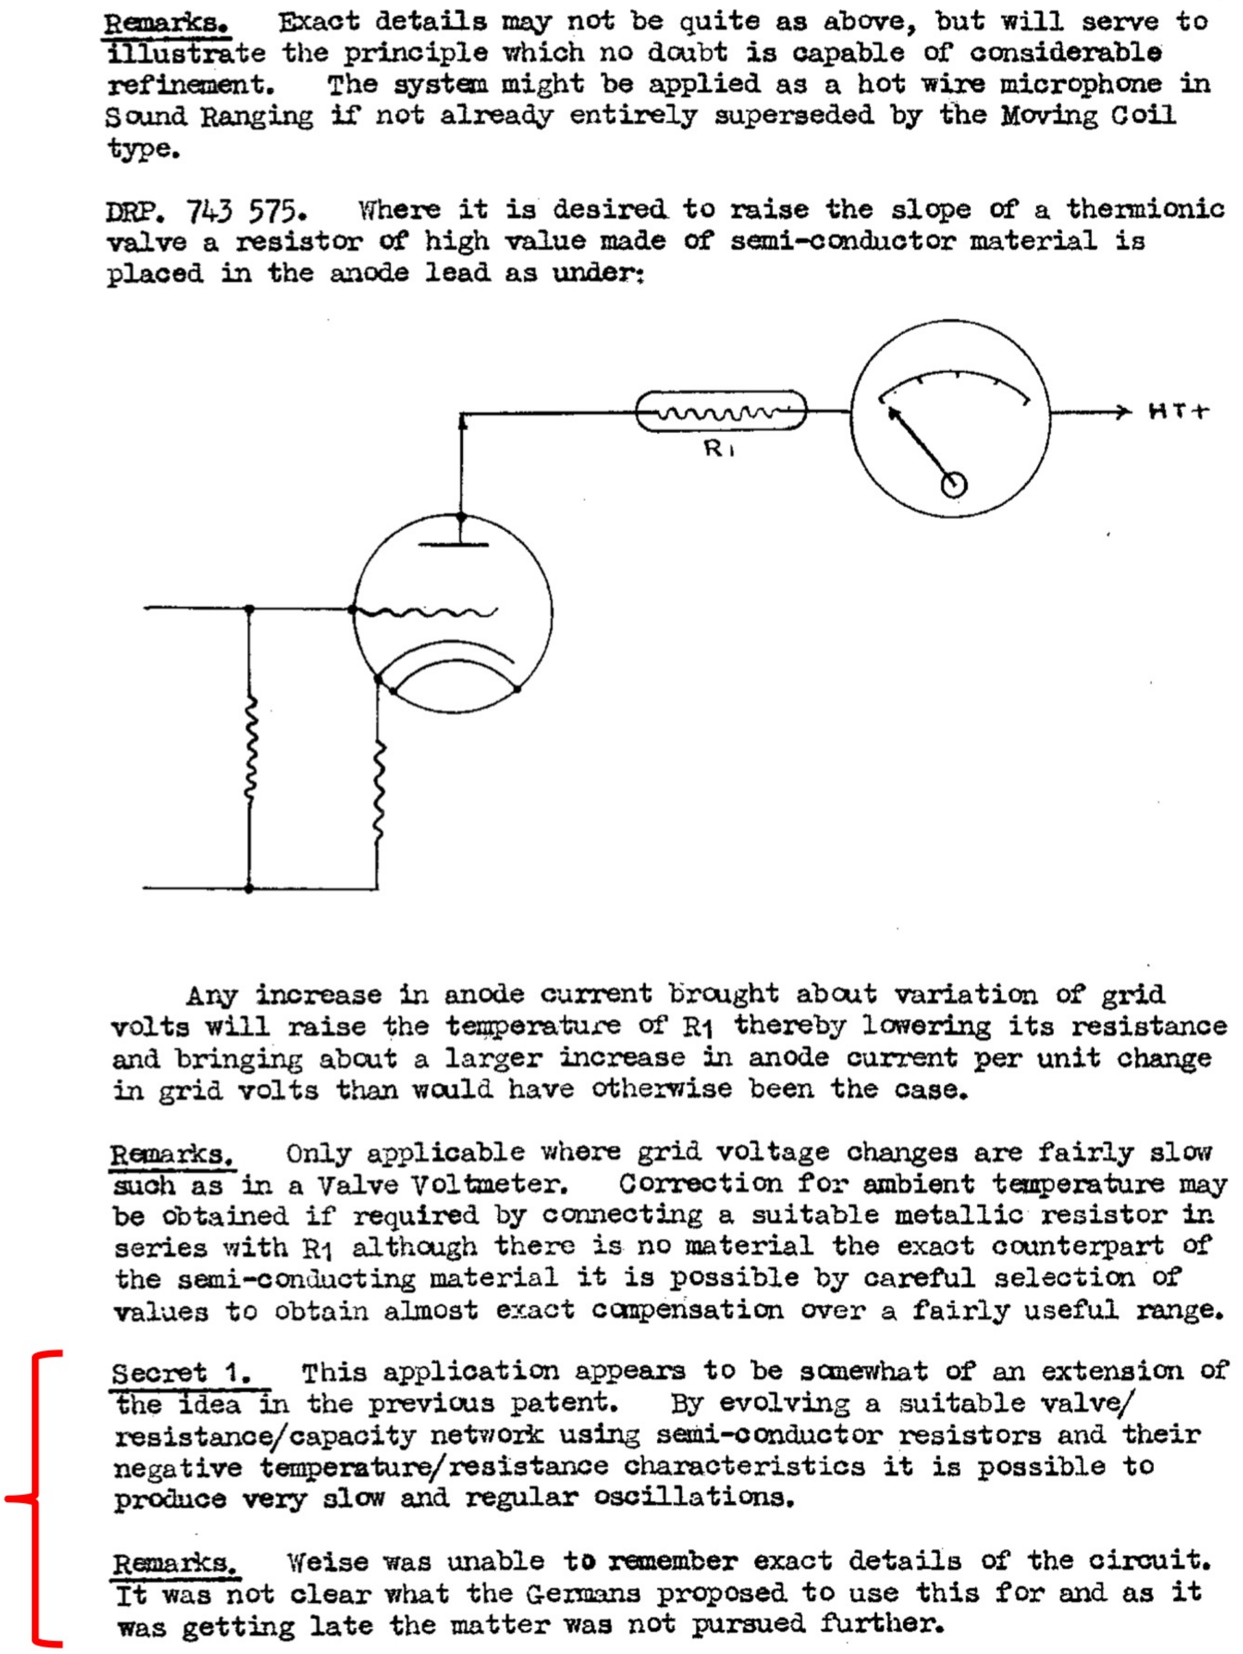
The following patents relate to inventions made by Weise:

DRP.	607 444	Carrier with two records of oscillations in one trace
"	618 982	Control resistor to diminish the starting time of cathodes
"	632 820	Network for the quick starting of cathodes in discharge tubes
"	641 680	Pipe-shaped high frequency furnace.
"	696 463	Manufacture of very thin semi-conductors.
"	697 174	Resistors of semi-conducting materials.
"	701 478	Electrical measurement of low gas and steam pressures
"	716 052	Equipment for fitting very thin semi-conductors
"	721 677	Stabiliser for D.C. and A.C. voltages.
"	730 251	Equipment for fitting very thin semi-conductors.
"	743 780	Measurements of the velocity of gases, slight changes in air pressure, and altitudes of aircraft.
"	743 575	Network to raise the slope of the characteristics of electron tubes.
Secret 1		Use of resistance controller as an amplifier and generator of slow electrical oscillations.
Secret 2		Instrument for measuring the inclination of ships, incorporating semi-conductors of little inertia.

I questioned Weise as to details of some of these patents and obtained the following explanations:-

DRP 618 982. This patent relates to method of accelerating the warming up of indirectly heated cathodes. A voltage of some two or three times the working voltage of the heater is applied. The relay R at this stage is resting on its back contacts thereby short circuiting R_1. As soon as anode current commences R operates leaving R_1 in series thereby dropping the heater voltage to its normal value.

Figure B.65: Erwin Weise told Allied investigators that he “had demonstrated the possibility of using thin films or control electrodes in semi-conducting materials to provide control of current flow similar to the control of current flow in high vacuum tubes” to create “electronic amplifiers without vacuum.”



Remarks. Exact details may not be quite as above, but will serve to illustrate the principle which no doubt is capable of considerable refinement. The system might be applied as a hot wire microphone in Sound Ranging if not already entirely superseded by the Moving Coil type.

DRP. 743 575. Where it is desired to raise the slope of a thermionic valve a resistor of high value made of semi-conductor material is placed in the anode lead as under:

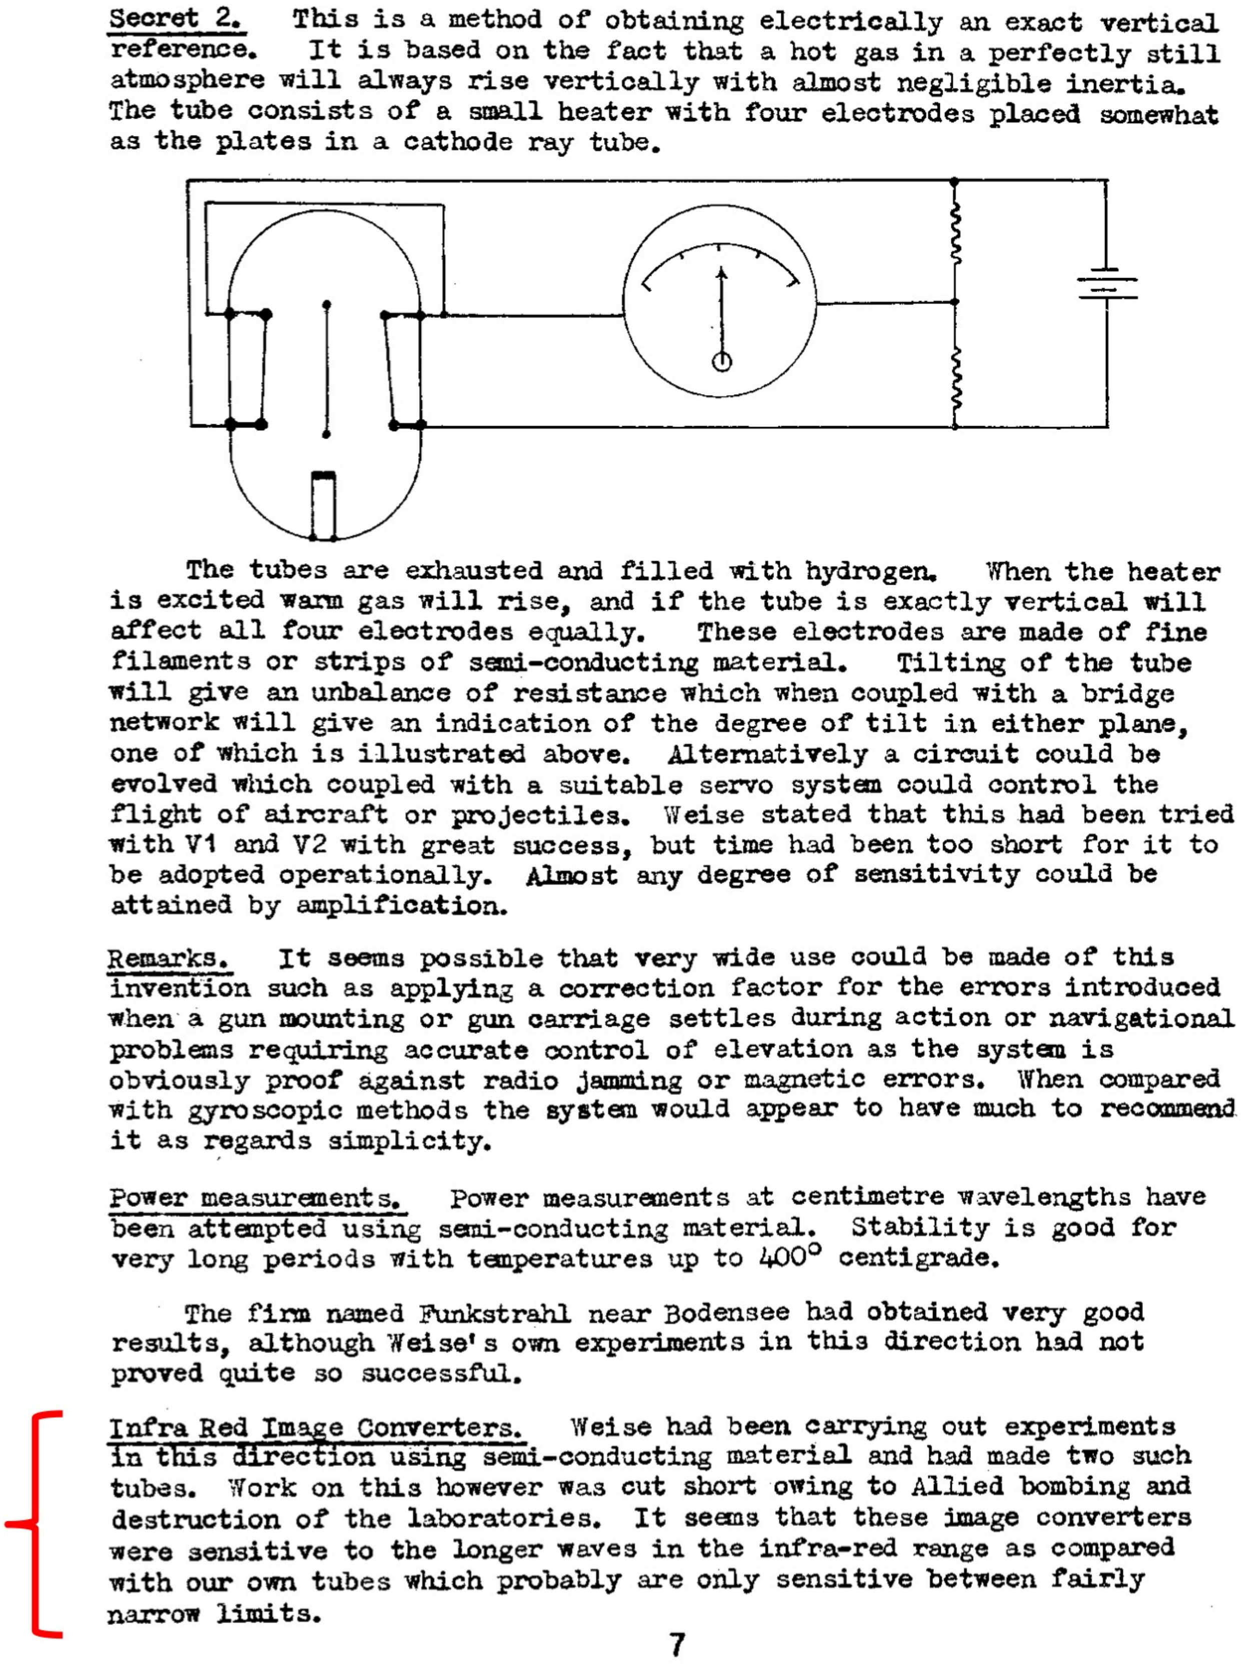
Any increase in anode current brought about variation of grid volts will raise the temperature of R1 thereby lowering its resistance and bringing about a larger increase in anode current per unit change in grid volts than would have otherwise been the case.

Remarks. Only applicable where grid voltage changes are fairly slow such as in a Valve Voltmeter. Correction for ambient temperature may be obtained if required by connecting a suitable metallic resistor in series with R1 although there is no material the exact counterpart of the semi-conducting material it is possible by careful selection of values to obtain almost exact compensation over a fairly useful range.

Secret 1. This application appears to be somewhat of an extension of the idea in the previous patent. By evolving a suitable valve/resistance/capacity network using semi-conductor resistors and their negative temperature/resistance characteristics it is possible to produce very slow and regular oscillations.

Remarks. Weise was unable to remember exact details of the circuit. It was not clear what the Germans proposed to use this for and as it was getting late the matter was not pursued further.

Figure B.66: Erwin Weise told Allied investigators that he "had demonstrated the possibility of using thin films or control electrodes in semi-conducting materials to provide control of current flow similar to the control of current flow in high vacuum tubes" to create "electronic amplifiers without vacuum."



Secret 2. This is a method of obtaining electrically an exact vertical reference. It is based on the fact that a hot gas in a perfectly still atmosphere will always rise vertically with almost negligible inertia. The tube consists of a small heater with four electrodes placed somewhat as the plates in a cathode ray tube.

The tubes are exhausted and filled with hydrogen. When the heater is excited warm gas will rise, and if the tube is exactly vertical will affect all four electrodes equally. These electrodes are made of fine filaments or strips of semi-conducting material. Tilting of the tube will give an unbalance of resistance which when coupled with a bridge network will give an indication of the degree of tilt in either plane, one of which is illustrated above. Alternatively a circuit could be evolved which coupled with a suitable servo system could control the flight of aircraft or projectiles. Weise stated that this had been tried with V1 and V2 with great success, but time had been too short for it to be adopted operationally. Almost any degree of sensitivity could be attained by amplification.

Remarks. It seems possible that very wide use could be made of this invention such as applying a correction factor for the errors introduced when a gun mounting or gun carriage settles during action or navigational problems requiring accurate control of elevation as the system is obviously proof against radio jamming or magnetic errors. When compared with gyroscopic methods the system would appear to have much to recommend it as regards simplicity.

Power measurements. Power measurements at centimetre wavelengths have been attempted using semi-conducting material. Stability is good for very long periods with temperatures up to 400° centigrade.

The firm named Funkstrahl near Bodensee had obtained very good results, although Weise's own experiments in this direction had not proved quite so successful.

Infra Red Image Converters. Weise had been carrying out experiments in this direction using semi-conducting material and had made two such tubes. Work on this however was cut short owing to Allied bombing and destruction of the laboratories. It seems that these image converters were sensitive to the longer waves in the infra-red range as compared with our own tubes which probably are only sensitive between fairly narrow limits.

7

Figure B.67: Erwin Weise told Allied investigators that he “had demonstrated the possibility of using thin films or control electrodes in semi-conducting materials to provide control of current flow similar to the control of current flow in high vacuum tubes” to create “electronic amplifiers without vacuum.”

REICHSPATENTAMT

PATENTSCHRIFT

№ 721 677

KLASSE **21c** GRUPPE 67 70

P 81100 VIIId/21c

Erwin Weise in Berlin-Charlottenburg

ist als Erfinder genannt worden.

Patent-Treuhand-Gesellschaft für elektrische Glühlampen m. b. H. in Berlin

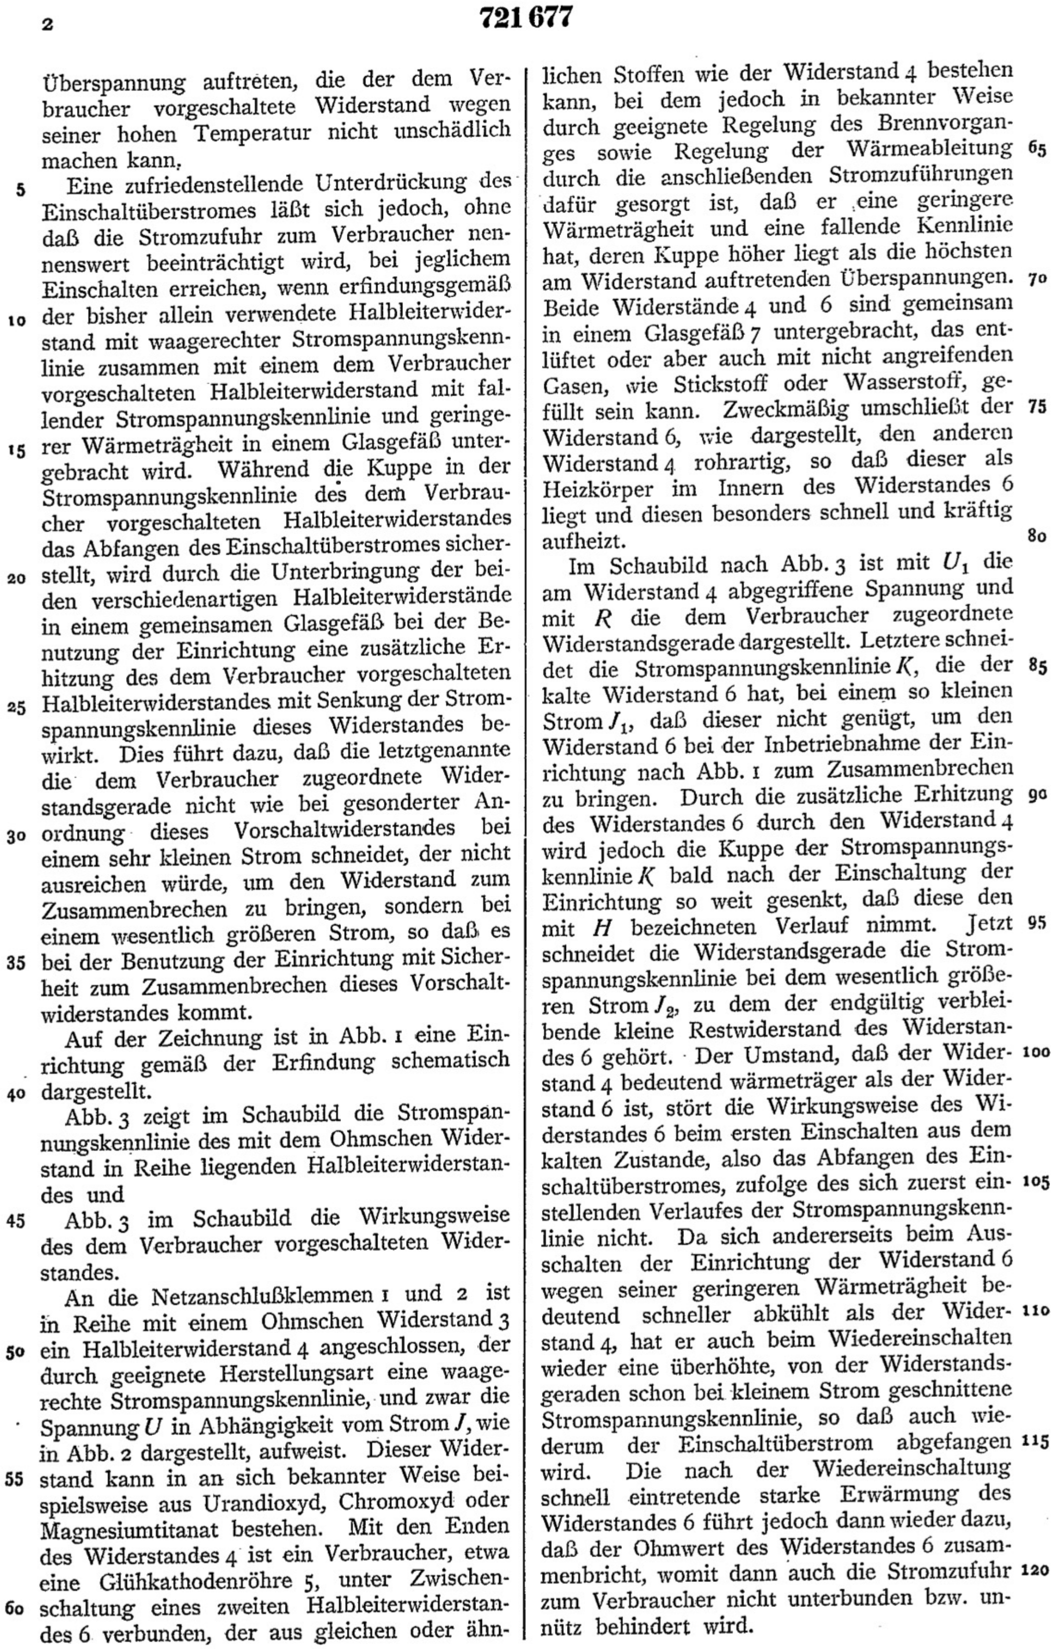
Einrichtung zur Entnahme gleichbleibender Gleich- oder Wechselspannung aus Netzen mit schwankender Spannung

Patentiert im Deutschen Reich vom 3. August 1940 an

Patenterteilung bekanntgemacht am 7. Mai 1942

Um aus Netzen mit schwankender Spannung gleichbleibende Gleich- oder Wechselspannung entnehmen zu können, ist es bekannt, den Verbraucher, etwa eine Glühkathodenröhre, an die Enden eines mit einem Ohmschen Widerstand in Reihe geschalteten Halbleiterwiderstandes mit waagerecht bzw. parallel zur Stromachse verlaufender Stromspannungskennlinie anzuschließen, so daß der Verbraucher parallel zum Halbleiterwiderstand liegt. Diese Schalteinrichtung hat den Nachteil, daß beim Anlegen der Klemmenspannung der Halbleiterwiderstand noch kalt ist, also einen verhältnismäßig großen Widerstandwert aufweist. An ihm liegt daher für eine gewisse Zeit eine große Spannung, die damit ebenfalls am Verbraucher liegt. Diese führt zu Überlastungen, die z. B. für Glühkathoden schädlich sind. Würde man, um diesen Nachteil zu beheben, dem Verbraucher in an sich bekannter Weise einen den Einschaltüberstrom dämpfenden Halbleiterwiderstand vorschalten, so müßte die Wärmeträgheit des letzteren größer sein als die Wärmeträgheit des parallel zum Verbraucher liegenden Widerstandes, damit der vorgeschaltete Widerstand erst dann in seinem Ohmwert zusammenbricht, wenn der parallel liegende Widerstand bereits seine endgültige Temperatur weitgehend erreicht hat. Eine derartige Einrichtung hätte jedoch den großen Nachteil, daß beim Ausschalten und zu frühen Wiedereinschalten der dem Verbraucher vorgeschaltete Widerstand wegen seiner größeren Trägheit noch warm sein kann, wenn sich der andere parallel zum Verbraucher liegende Widerstand bereits abgekühlt hat. Es wird dann aber beim Wiedereinschalten eine große

Figure B.68: Erwin Weise told Allied investigators that he “had demonstrated the possibility of using thin films or control electrodes in semi-conducting materials to provide control of current flow similar to the control of current flow in high vacuum tubes” to create “electronic amplifiers without vacuum.”



2 **721 677**

Überspannung auftreten, die der dem Verbraucher vorgeschaltete Widerstand wegen seiner hohen Temperatur nicht unschädlich machen kann.

Eine zufriedenstellende Unterdrückung des Einschaltüberstromes läßt sich jedoch, ohne daß die Stromzufuhr zum Verbraucher nennenswert beeinträchtigt wird, bei jeglichem Einschalten erreichen, wenn erfindungsgemäß der bisher allein verwendete Halbleiterwiderstand mit waagerechter Stromspannungskennlinie zusammen mit einem dem Verbraucher vorgeschalteten Halbleiterwiderstand mit fallender Stromspannungskennlinie und geringerer Wärmeträgheit in einem Glasgefäß untergebracht wird. Während die Kuppe in der Stromspannungskennlinie des dem Verbraucher vorgeschalteten Halbleiterwiderstandes das Abfangen des Einschaltüberstromes sicherstellt, wird durch die Unterbringung der beiden verschiedenartigen Halbleiterwiderstände in einem gemeinsamen Glasgefäß bei der Benutzung der Einrichtung eine zusätzliche Erhitzung des dem Verbraucher vorgeschalteten Halbleiterwiderstandes mit Senkung der Stromspannungskennlinie dieses Widerstandes bewirkt. Dies führt dazu, daß die letztgenannte die dem Verbraucher zugeordnete Widerstandsgerade nicht wie bei gesonderter Anordnung dieses Vorschaltwiderstandes bei einem sehr kleinen Strom schneidet, der nicht ausreichen würde, um den Widerstand zum Zusammenbrechen zu bringen, sondern bei einem wesentlich größeren Strom, so daß es bei der Benutzung der Einrichtung mit Sicherheit zum Zusammenbrechen dieses Vorschaltwiderstandes kommt.

Auf der Zeichnung ist in Abb. 1 eine Einrichtung gemäß der Erfindung schematisch dargestellt.

Abb. 3 zeigt im Schaubild die Stromspannungskennlinie des mit dem Ohmschen Widerstand in Reihe liegenden Halbleiterwiderstandes und

Abb. 3 im Schaubild die Wirkungsweise des dem Verbraucher vorgeschalteten Widerstandes.

An die Netzanschlußklemmen 1 und 2 ist in Reihe mit einem Ohmschen Widerstand 3 ein Halbleiterwiderstand 4 angeschlossen, der durch geeignete Herstellungsart eine waagerechte Stromspannungskennlinie, und zwar die Spannung U in Abhängigkeit vom Strom J, wie in Abb. 2 dargestellt, aufweist. Dieser Widerstand kann in an sich bekannter Weise beispielsweise aus Urandioxyd, Chromoxyd oder Magnesiumtitanat bestehen. Mit den Enden des Widerstandes 4 ist ein Verbraucher, etwa eine Glühkathodenröhre 5, unter Zwischenschaltung eines zweiten Halbleiterwiderstandes 6 verbunden, der aus gleichen oder ähnlichen Stoffen wie der Widerstand 4 bestehen kann, bei dem jedoch in bekannter Weise durch geeignete Regelung des Brennvorganges sowie Regelung der Wärmeableitung durch die anschließenden Stromzuführungen dafür gesorgt ist, daß er eine geringere Wärmeträgheit und eine fallende Kennlinie hat, deren Kuppe höher liegt als die höchsten am Widerstand auftretenden Überspannungen. Beide Widerstände 4 und 6 sind gemeinsam in einem Glasgefäß 7 untergebracht, das entlüftet oder aber auch mit nicht angreifenden Gasen, wie Stickstoff oder Wasserstoff, gefüllt sein kann. Zweckmäßig umschließt der Widerstand 6, wie dargestellt, den anderen Widerstand 4 rohrartig, so daß dieser als Heizkörper im Innern des Widerstandes 6 liegt und diesen besonders schnell und kräftig aufheizt.

Im Schaubild nach Abb. 3 ist mit U_1 die am Widerstand 4 abgegriffene Spannung und mit R die dem Verbraucher zugeordnete Widerstandsgerade dargestellt. Letztere schneidet die Stromspannungskennlinie K, die der kalte Widerstand 6 hat, bei einem so kleinen Strom J_1, daß dieser nicht genügt, um den Widerstand 6 bei der Inbetriebnahme der Einrichtung nach Abb. 1 zum Zusammenbrechen zu bringen. Durch die zusätzliche Erhitzung des Widerstandes 6 durch den Widerstand 4 wird jedoch die Kuppe der Stromspannungskennlinie K bald nach der Einschaltung der Einrichtung so weit gesenkt, daß diese den mit H bezeichneten Verlauf nimmt. Jetzt schneidet die Widerstandsgerade die Stromspannungskennlinie bei dem wesentlich größeren Strom J_2, zu dem der endgültig verbleibende kleine Restwiderstand des Widerstandes 6 gehört. Der Umstand, daß der Widerstand 4 bedeutend wärmeträger als der Widerstand 6 ist, stört die Wirkungsweise des Widerstandes 6 beim ersten Einschalten aus dem kalten Zustande, also das Abfangen des Einschaltüberstromes, zufolge des sich zuerst einstellenden Verlaufes der Stromspannungskennlinie nicht. Da sich andererseits beim Ausschalten der Einrichtung der Widerstand 6 wegen seiner geringeren Wärmeträgheit bedeutend schneller abkühlt als der Widerstand 4, hat er auch beim Wiedereinschalten wieder eine überhöhte, von der Widerstandsgeraden schon bei kleinem Strom geschnittene Stromspannungskennlinie, so daß auch wiederum der Einschaltüberstrom abgefangen wird. Die nach der Wiedereinschaltung schnell eintretende starke Erwärmung des Widerstandes 6 führt jedoch dann wieder dazu, daß der Ohmwert des Widerstandes 6 zusammenbricht, womit dann auch die Stromzufuhr zum Verbraucher nicht unterbunden bzw. unnütz behindert wird.

UNITED STATES PATENT OFFICE

2,648,805

CONTROLLABLE ELECTRIC RESISTANCE DEVICE

Eberhard Hermann Georg Spenke, Frank Wenzel Georg Rose, and Erich Gerhard Rudolf Waldkötter, Pretzfeld, Germany, assignors to Siemens-Schuckertwerke, Aktiengesellschaft, Berlin-Siemensstadt, Germany, a corporation of Germany

Application October 21, 1950, Serial No. 191,360
In Germany May 30, 1949

18 Claims. (Cl. 317—235)

Our invention relates to controllable electric resistors and the like devices for controlling electric circuits.

It is an object of our invention to devise a resistance device of a static type that, though not requiring an electronic vacuum or gaseous discharge, is controllable by the direct application of a control voltage and operates virtually free of inertia, thus being applicable for a large variety of purposes in much the same way as electronic amplifier or control tubes and particularly wherever an electric current path is to be controlled or regulated by minute control energy.

Another object of our invention is to provide a bodily electric resistor of controllable resistance and to obviate the need for providing it with mechanically movable or otherwise mechanically actuated or thermally responsive resistance control members.

It is also an object of the invention to make the resistive behaviour of electric resistors of the solid-material type adaptable to different selectively available resistance characteristics in one or both directions of current flow, a subsidiary object being to secure a characteristic of the saturation type configuration.

An object of the invention is further to devise rectifier units of the dry or junction type that can be controlled by application of control voltage to provide a controllable rectified output.

Another object of the invention is to provide industrially suitable methods of making the novel resistance and rectifier units.

In order to achieve these and the more specific objects apparent from the following, our invention takes advantage of the barrier-layer effect known from semiconductors such as selenium. Such semiconductors and various other substances form a barrier layer where they are in contact engagement with a suitable metal. The barrier layers offer a high resistance to the passage of electric current and are dependent, as regards occurrence and effectiveness, upon the magnitude of the impressed voltage. This behaviour is utilized, for instance, in the so-called dry rectifiers in which a thin semiconductive layer is contacted at one side by a barrier-free contact element and at the other side by a barrier-forming contact element, the so-called barrier electrode. When a voltage of a given direction is applied between the two contact elements, a barrier layer is produced which practically blocks the current passage in this direction or maintains any remaining current flow within very small magnitudes. It has now been observed that the thickness of the barrier layer thus produced is dependent upon the magnitude of the impressed voltage. With an increasing voltage, the layer of high resistance expands more deeply into the semiconductive or other resistance material susceptible to the barrier layer effect. The portion of the resistance material not occupied by the barrier layer is consequently diminished by the thickness of the barrier layer.

The just-mentioned phenomenon is utilized by the invention in the following manner. According to the invention, a body of resistance material susceptible to barrier-layer formation is provided with a barrier electrode arranged to form in the resistance body a diaphragm-shaped barrier layer across the current path to be controlled, the dimensions of the diaphragm opening being dependent upon the impressed voltage.

The invention involves a variety of possibilities for the design of such resistance devices. According to one feature of the invention, the resistor proper is a semiconductive body joined with two terminals or connector electrodes, while the barrier diaphragm disposed in the current path of this resistor body is formed by a barrier electrode located at a place where the current path is strongly constricted. The constriction of the current flow lines can be secured by a corresponding shaping of the semiconductive body, preferably by giving the semiconductive body a spot of very small dimensions in one or both directions transverse to the flow direction of the current to be controlled, and locating the controlling barrier electrode at or near this spot and substantially around the constricted current path.

The term "connector electrode" in this specification as well as in the claims refers to the barrier-free contact member or terminal which engages the semiconductive or other resistance body. The terms "barrier electrode" and "diaphragm electrode" refer to electrode members which contact the barrier susceptible resistance body and form together therewith a barrier layer due to impressed voltage.

The foregoing and other features of the invention will be apparent from the following description of the embodiments exemplified by the drawing, in which:

Figs. 1 and 2 show respective resistance devices according to the invention by part sectional front views;

Figs. 3 and 4 show another resistance device according to the invention in a sectional front view and a sectional top view, the respective sectional planes being indicated by the line III—III in Fig. 4 and the line IV—IV in Fig. 3;

Fig. 13 is a sectional view of another embodiment of a controllable rectifying device according to the invention; and

Fig. 14 is a similar view of an embodiment of a controllable rectifying apparatus with a saturation characteristic.

The resistor according to Fig. 1 has an insulating base plate **1** on which a barrier-susceptible or semiconductive resistance body is mounted. This body is composed of three parts **2**, **3** and **4** and is intimately contacted by two connector electrodes **5** and **6** also mounted on the insulating plate **1**. The intermediate resistor portion **3** has much smaller dimensions than the bordering portions **2** and **4** and is intimately contacted by a barrier electrode **7** which serves to provide a controllable barrier diaphragm. The connecting leads (in Figs. 1 through 4) are denoted by a_1 and a_2, and the control lead is denoted *s*. As apparent from Fig. 1, the middle part **3** of the resistance body is very thin, although its width in the direction across the plane of illustration may be large. Generally, however, the width of portion **3** in at least one of the directions transverse to the current path (i. e. penpendicular to the plane of illustration) is very small.

For operating the resistance device, the two connector electrodes **5** and **6** are series connected by the respective leads a_1 and a_2 into the circuit to be controlled. The control or regulation of the resistance is effected by means of a control voltage impressed between the barrier electrode **7** and one of the connector electrodes. The electrode **7** contacts the semiconductor **3** in the manner known from the technique of dry rectifiers so that the application of control voltage results in the formation of a barrier layer which extends from the barrier electrode **7** into the body **3**. The electrode **7** fully covers the top and bottom sides of body **3**, or the electrode fully encloses this body so that the barrier layer, if growing from electrode **7** fully into the body **3**, would not leave any free spot for the passage of current. Consequently, the effect is as if a diaphragm of controlled opening area is placed into the resistive current path between the two connector electrodes **5** and **6**. The opening width of the barrier diaphragm depends, as explained, upon the magnitude of the impressed control voltage, the thickness of the barrier layer being larger with larger control voltages, so that the available cross section of current flow and hence the effective resistance are varied in the rhythm of the control voltage.

4

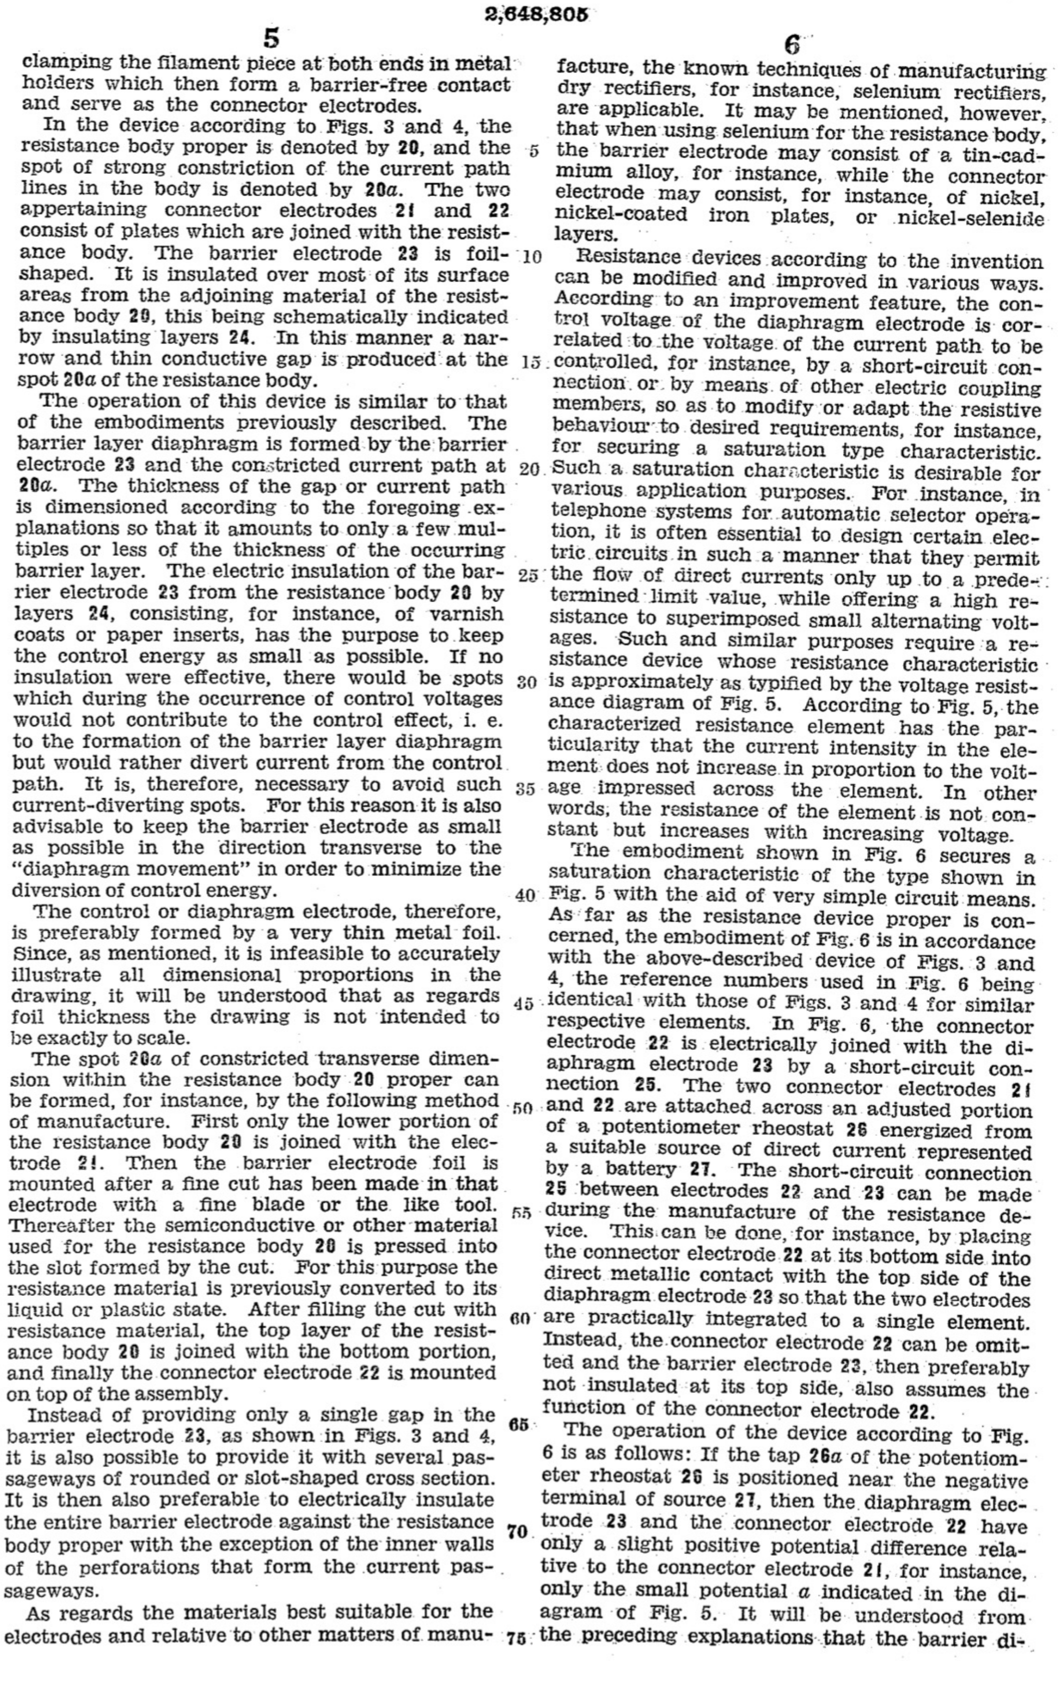
To form the resistor proper, i. e. the semiconductive body in the embodiment of Fig. 1, of three portions has the purpose to constrict or bunch the lines of current flow at the spot of the diaphragm. This design is based on the consideration that the thickness of the resulting barrier layer as such is very small. It is advisable, therefore, to adapt the transverse dimensions of the resistor body at the diaphragm spot to the order of magnitude of the resulting barrier layer thickness. In other words, it is essential to give the dimension of the current path in the direction of the "diaphragm movement" at the place of the diaphragm electrode a magnitude of only a few multiples, for instance, twice or three times the extent of the barrier layer thickness occurring in the particular resistor substance used, although the dimensions of the constricted resistor portion may be smaller if possible. The term "diaphragm movement" as used in the foregoing and hereafter is intended to refer to the opening and closing directions, i. e. to the growth and decline of the barrier layer under the effect of the control voltage.

In Fig. 2 the resistor proper, consisting of a semiconductor, is denoted by **10**. Joined with this resistor is a plate-shaped connector electrode **11**. The resistance body **10** has a filament-shaped extension **10*a*** to which is joined a second connector electrode **12** and a barrier electrode **13**. The barrier electrode **13** completely surrounds the filament extension **10*a***. For reasons mentioned in the following, the barrier electrode **13** is insulated from the main resistance body **10** by being somewhat spaced therefrom.

The functioning of the resistance device according to Fig. 2 is largely similar to that of Fig. 1. The special shape of the semiconductive assembly **10**, **10*a*** serves the purpose to provide a spot of a strong constriction of the current path lines within the semiconductive body. This is easily achieved by the provision of the filament extension **10*a***. It may be mentioned that for the sake of lucid illustration the representation in the drawing is not correct according to measure. In particular, the electrode **13** is shown thicker than actually necessary. In reality, this electrode may be very thin. This applies even more to the filament shaped extension **10*a***. The filament may be produced, for instance, by immersing a glass rod or the like into a molten bath of selenium or another semiconductive or otherwise suitable material and then removing the rod, thus drawing a filament from the bath. By inspecting the filament under a microscope or by other suitable methods, those parts of the filaments are selected which have the desired thickness. The selected pieces of filaments are than used as the filament-shaped extensions **10*a***. The barrier electrode **13** can be joined with the filament by immersing the filament, or the selected filament section of limited length, in a molten metal or by depositing in vacuum a metal coating on the filament.

Departing from the embodiment of Fig. 2, it is also possible to build up the entire controllable resistance device with the aid of a filament-shaped resistance body of suitable material. This can be done by mounting a barrier electrode in the above-mentioned manner on a limited length of the filament-shaped piece of material and attaching the connector electrodes to the same piece of filament material, for instance, by

Figure B.76: Frank Rose, Eberhard Spenke, and Erich Waldkötter filed detailed patent applications on transistors in 1949, likely based on wartime work.



2,648,805

5

clamping the filament piece at both ends in metal holders which then form a barrier-free contact and serve as the connector electrodes.

In the device according to Figs. 3 and 4, the resistance body proper is denoted by **20**, and the spot of strong constriction of the current path lines in the body is denoted by **20a**. The two appertaining connector electrodes **21** and **22** consist of plates which are joined with the resistance body. The barrier electrode **23** is foil-shaped. It is insulated over most of its surface areas from the adjoining material of the resistance body **20**, this being schematically indicated by insulating layers **24**. In this manner a narrow and thin conductive gap is produced at the spot **20a** of the resistance body.

The operation of this device is similar to that of the embodiments previously described. The barrier layer diaphragm is formed by the barrier electrode **23** and the constricted current path at **20a**. The thickness of the gap or current path is dimensioned according to the foregoing explanations so that it amounts to only a few multiples or less of the thickness of the occurring barrier layer. The electric insulation of the barrier electrode **23** from the resistance body **20** by layers **24**, consisting, for instance, of varnish coats or paper inserts, has the purpose to keep the control energy as small as possible. If no insulation were effective, there would be spots which during the occurrence of control voltages would not contribute to the control effect, i. e. to the formation of the barrier layer diaphragm but would rather divert current from the control path. It is, therefore, necessary to avoid such current-diverting spots. For this reason it is also advisable to keep the barrier electrode as small as possible in the direction transverse to the "diaphragm movement" in order to minimize the diversion of control energy.

The control or diaphragm electrode, therefore, is preferably formed by a very thin metal foil. Since, as mentioned, it is infeasible to accurately illustrate all dimensional proportions in the drawing, it will be understood that as regards foil thickness the drawing is not intended to be exactly to scale.

The spot **20a** of constricted transverse dimension within the resistance body **20** proper can be formed, for instance, by the following method of manufacture. First only the lower portion of the resistance body **20** is joined with the electrode **21**. Then the barrier electrode foil is mounted after a fine cut has been made in that electrode with a fine blade or the like tool. Thereafter the semiconductive or other material used for the resistance body **20** is pressed into the slot formed by the cut. For this purpose the resistance material is previously converted to its liquid or plastic state. After filling the cut with resistance material, the top layer of the resistance body **20** is joined with the bottom portion, and finally the connector electrode **22** is mounted on top of the assembly.

Instead of providing only a single gap in the barrier electrode **23**, as shown in Figs. 3 and 4, it is also possible to provide it with several passageways of rounded or slot-shaped cross section. It is then also preferable to electrically insulate the entire barrier electrode against the resistance body proper with the exception of the inner walls of the perforations that form the current passageways.

As regards the materials best suitable for the electrodes and relative to other matters of manufacture, the known techniques of manufacturing dry rectifiers, for instance, selenium rectifiers, are applicable. It may be mentioned, however, that when using selenium for the resistance body, the barrier electrode may consist of a tin-cadmium alloy, for instance, while the connector electrode may consist, for instance, of nickel, nickel-coated iron plates, or nickel-selenide layers.

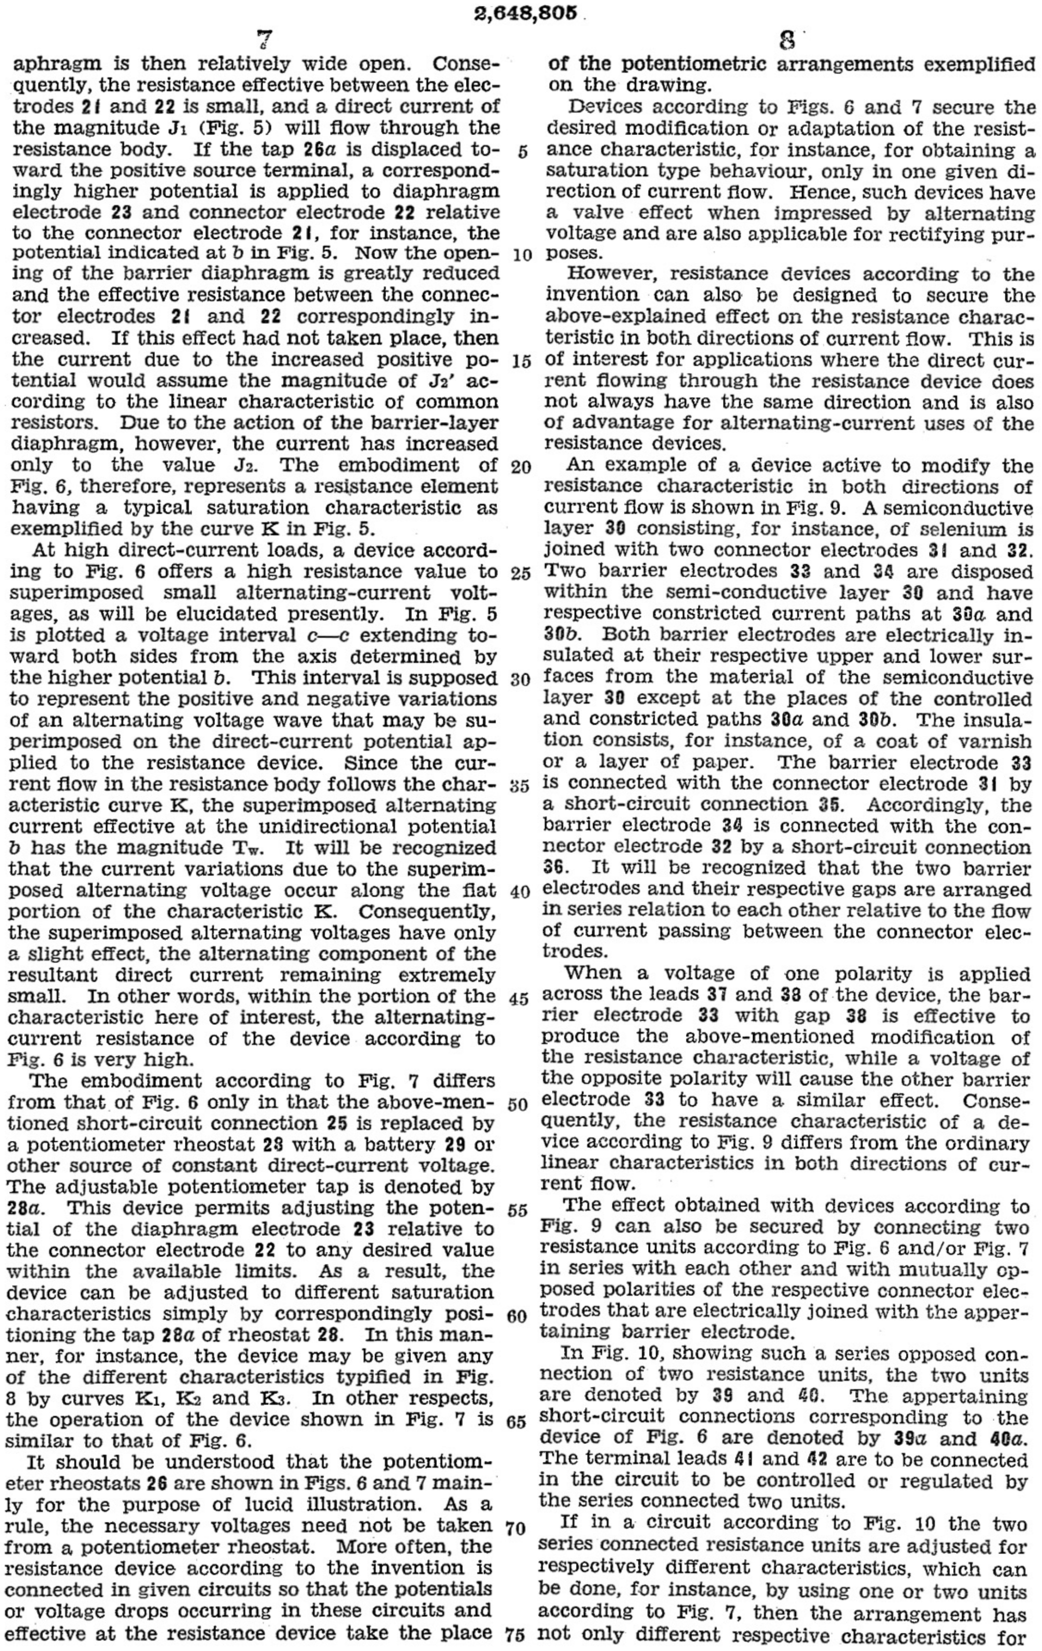
6

Resistance devices according to the invention can be modified and improved in various ways. According to an improvement feature, the control voltage of the diaphragm electrode is correlated to the voltage of the current path to be controlled, for instance, by a short-circuit connection or by means of other electric coupling members, so as to modify or adapt the resistive behaviour to desired requirements, for instance, for securing a saturation type characteristic. Such a saturation characteristic is desirable for various application purposes. For instance, in telephone systems for automatic selector operation, it is often essential to design certain electric circuits in such a manner that they permit the flow of direct currents only up to a predetermined limit value, while offering a high resistance to superimposed small alternating voltages. Such and similar purposes require a resistance device whose resistance characteristic is approximately as typified by the voltage resistance diagram of Fig. 5. According to Fig. 5, the characterized resistance element has the particularity that the current intensity in the element does not increase in proportion to the voltage impressed across the element. In other words, the resistance of the element is not constant but increases with increasing voltage.

The embodiment shown in Fig. 6 secures a saturation characteristic of the type shown in Fig. 5 with the aid of very simple circuit means. As far as the resistance device proper is concerned, the embodiment of Fig. 6 is in accordance with the above-described device of Figs. 3 and 4, the reference numbers used in Fig. 6 being identical with those of Figs. 3 and 4 for similar respective elements. In Fig. 6, the connector electrode **22** is electrically joined with the diaphragm electrode **23** by a short-circuit connection **25**. The two connector electrodes **21** and **22** are attached across an adjusted portion of a potentiometer rheostat **26** energized from a suitable source of direct current represented by a battery **27**. The short-circuit connection **25** between electrodes **22** and **23** can be made during the manufacture of the resistance device. This can be done, for instance, by placing the connector electrode **22** at its bottom side into direct metallic contact with the top side of the diaphragm electrode **23** so that the two electrodes are practically integrated to a single element. Instead, the connector electrode **22** can be omitted and the barrier electrode **23**, then preferably not insulated at its top side, also assumes the function of the connector electrode **22**.

The operation of the device according to Fig. 6 is as follows: If the tap **26a** of the potentiometer rheostat **26** is positioned near the negative terminal of source **27**, then the diaphragm electrode **23** and the connector electrode **22** have only a slight positive potential difference relative to the connector electrode **21**, for instance, only the small potential *a* indicated in the diagram of Fig. 5. It will be understood from the preceding explanations that the barrier di-

Figure B.77: Frank Rose, Eberhard Spenke, and Erich Waldkötter filed detailed patent applications on transistors in 1949, likely based on wartime work.



aphragm is then relatively wide open. Consequently, the resistance effective between the electrodes **21** and **22** is small, and a direct current of the magnitude J_1 (Fig. 5) will flow through the resistance body. If the tap **26***a* is displaced toward the positive source terminal, a correspondingly higher potential is applied to diaphragm electrode **23** and connector electrode **22** relative to the connector electrode **21**, for instance, the potential indicated at *b* in Fig. 5. Now the opening of the barrier diaphragm is greatly reduced and the effective resistance between the connector electrodes **21** and **22** correspondingly increased. If this effect had not taken place, then the current due to the increased positive potential would assume the magnitude of J_2' according to the linear characteristic of common resistors. Due to the action of the barrier-layer diaphragm, however, the current has increased only to the value J_2. The embodiment of Fig. 6, therefore, represents a resistance element having a typical saturation characteristic as exemplified by the curve K in Fig. 5.

At high direct-current loads, a device according to Fig. 6 offers a high resistance value to superimposed small alternating-current voltages, as will be elucidated presently. In Fig. 5 is plotted a voltage interval *c*—*c* extending toward both sides from the axis determined by the higher potential *b*. This interval is supposed to represent the positive and negative variations of an alternating voltage wave that may be superimposed on the direct-current potential applied to the resistance device. Since the current flow in the resistance body follows the characteristic curve K, the superimposed alternating current effective at the unidirectional potential *b* has the magnitude T_w. It will be recognized that the current variations due to the superimposed alternating voltage occur along the flat portion of the characteristic K. Consequently, the superimposed alternating voltages have only a slight effect, the alternating component of the resultant direct current remaining extremely small. In other words, within the portion of the characteristic here of interest, the alternating-current resistance of the device according to Fig. 6 is very high.

The embodiment according to Fig. 7 differs from that of Fig. 6 only in that the above-mentioned short-circuit connection **25** is replaced by a potentiometer rheostat **28** with a battery **29** or other source of constant direct-current voltage. The adjustable potentiometer tap is denoted by **28***a*. This device permits adjusting the potential of the diaphragm electrode **23** relative to the connector electrode **22** to any desired value within the available limits. As a result, the device can be adjusted to different saturation characteristics simply by correspondingly positioning the tap **28***a* of rheostat **28**. In this manner, for instance, the device may be given any of the different characteristics typified in Fig. 8 by curves K_1, K_2 and K_3. In other respects, the operation of the device shown in Fig. 7 is similar to that of Fig. 6.

It should be understood that the potentiometer rheostats **26** are shown in Figs. 6 and 7 mainly for the purpose of lucid illustration. As a rule, the necessary voltages need not be taken from a potentiometer rheostat. More often, the resistance device according to the invention is connected in given circuits so that the potentials or voltage drops occurring in these circuits and effective at the resistance device take the place of the potentiometric arrangements exemplified on the drawing.

Devices according to Figs. 6 and 7 secure the desired modification or adaptation of the resistance characteristic, for instance, for obtaining a saturation type behaviour, only in one given direction of current flow. Hence, such devices have a valve effect when impressed by alternating voltage and are also applicable for rectifying purposes.

However, resistance devices according to the invention can also be designed to secure the above-explained effect on the resistance characteristic in both directions of current flow. This is of interest for applications where the direct current flowing through the resistance device does not always have the same direction and is also of advantage for alternating-current uses of the resistance devices.

An example of a device active to modify the resistance characteristic in both directions of current flow is shown in Fig. 9. A semiconductive layer **30** consisting, for instance, of selenium is joined with two connector electrodes **31** and **32**. Two barrier electrodes **33** and **34** are disposed within the semi-conductive layer **30** and have respective constricted current paths at **30***a* and **30***b*. Both barrier electrodes are electrically insulated at their respective upper and lower surfaces from the material of the semiconductive layer **30** except at the places of the controlled and constricted paths **30***a* and **30***b*. The insulation consists, for instance, of a coat of varnish or a layer of paper. The barrier electrode **33** is connected with the connector electrode **31** by a short-circuit connection **35**. Accordingly, the barrier electrode **34** is connected with the connector electrode **32** by a short-circuit connection **36**. It will be recognized that the two barrier electrodes and their respective gaps are arranged in series relation to each other relative to the flow of current passing between the connector electrodes.

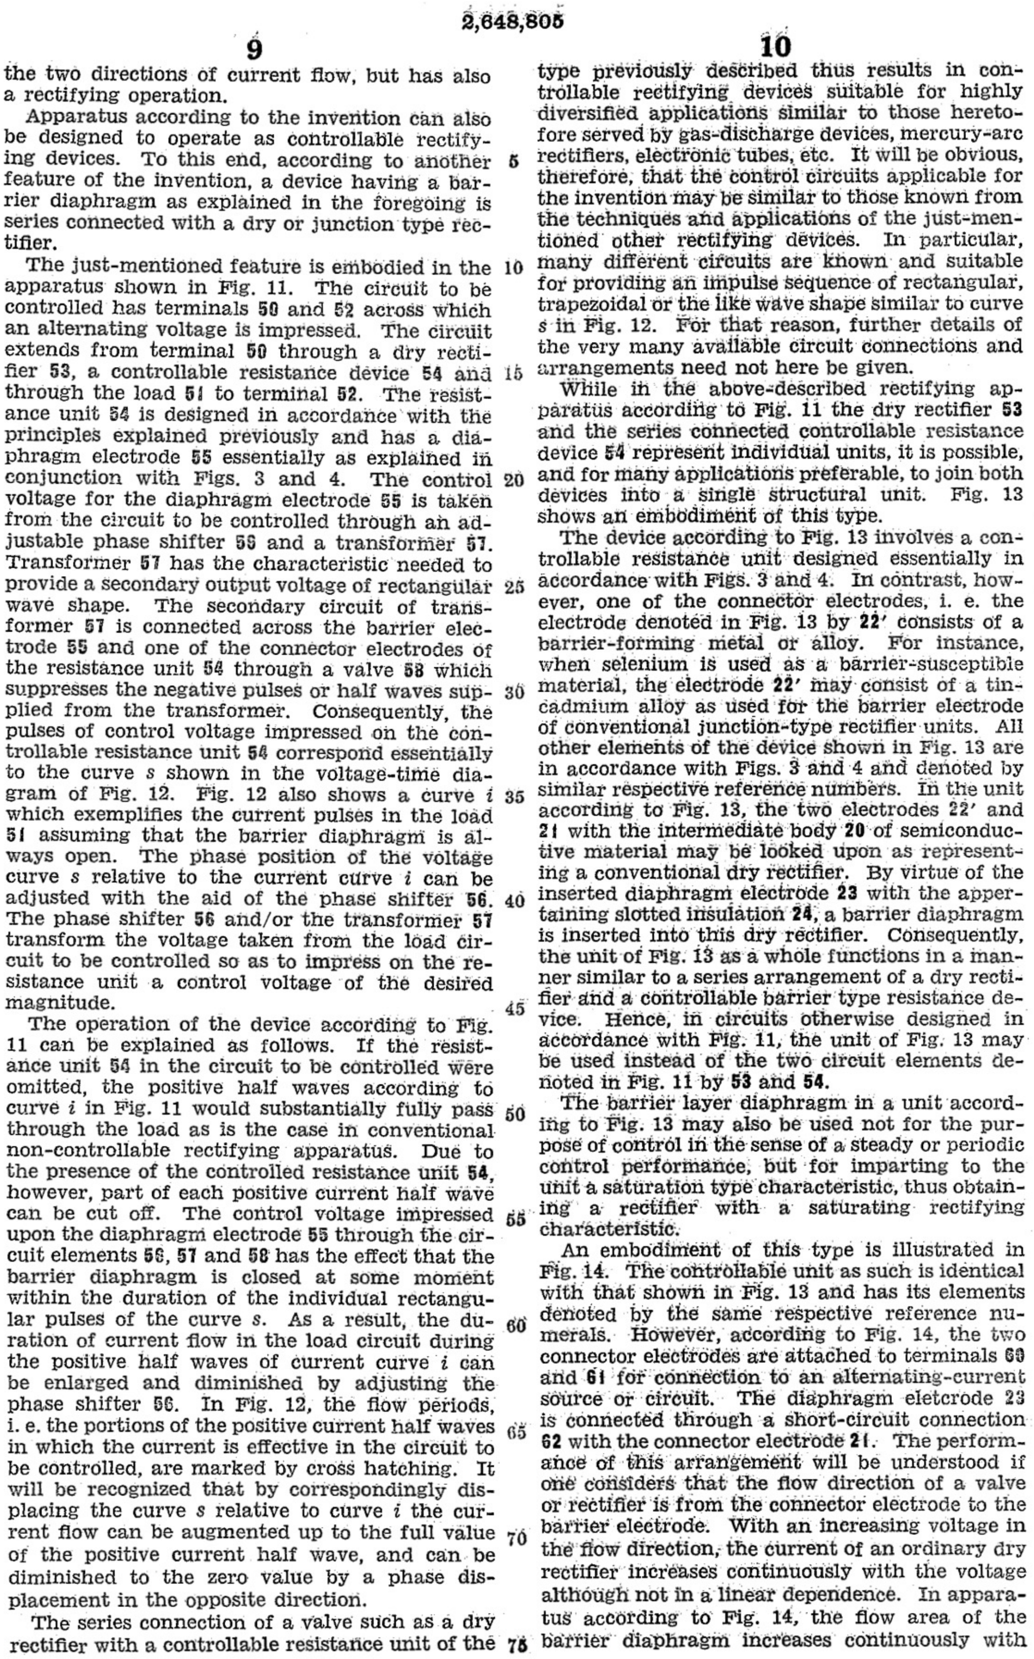
When a voltage of one polarity is applied across the leads **37** and **38** of the device, the barrier electrode **33** with gap **38** is effective to produce the above-mentioned modification of the resistance characteristic, while a voltage of the opposite polarity will cause the other barrier electrode **33** to have a similar effect. Consequently, the resistance characteristic of a device according to Fig. 9 differs from the ordinary linear characteristics in both directions of current flow.

The effect obtained with devices according to Fig. 9 can also be secured by connecting two resistance units according to Fig. 6 and/or Fig. 7 in series with each other and with mutually opposed polarities of the respective connector electrodes that are electrically joined with the appertaining barrier electrode.

In Fig. 10, showing such a series opposed connection of two resistance units, the two units are denoted by **39** and **40**. The appertaining short-circuit connections corresponding to the device of Fig. 6 are denoted by **39***a* and **40***a*. The terminal leads **41** and **42** are to be connected in the circuit to be controlled or regulated by the series connected two units.

If in a circuit according to Fig. 10 the two series connected resistance units are adjusted for respectively different characteristics, which can be done, for instance, by using one or two units according to Fig. 7, then the arrangement has not only different respective characteristics for

Figure B.78: Frank Rose, Eberhard Spenke, and Erich Waldkötter filed detailed patent applications on transistors in 1949, likely based on wartime work.



the two directions of current flow, but has also a rectifying operation.

Apparatus according to the invention can also be designed to operate as controllable rectifying devices. To this end, according to another feature of the invention, a device having a barrier diaphragm as explained in the foregoing is series connected with a dry or junction type rectifier.

The just-mentioned feature is embodied in the apparatus shown in Fig. 11. The circuit to be controlled has terminals **50** and **52** across which an alternating voltage is impressed. The circuit extends from terminal **50** through a dry rectifier **53**, a controllable resistance device **54** and through the load **51** to terminal **52**. The resistance unit **54** is designed in accordance with the principles explained previously and has a diaphragm electrode **55** essentially as explained in conjunction with Figs. 3 and 4. The control voltage for the diaphragm electrode **55** is taken from the circuit to be controlled through an adjustable phase shifter **56** and a transformer **57**. Transformer **57** has the characteristic needed to provide a secondary output voltage of rectangular wave shape. The secondary circuit of transformer **57** is connected across the barrier electrode **55** and one of the connector electrodes of the resistance unit **54** through a valve **58** which suppresses the negative pulses or half waves supplied from the transformer. Consequently, the pulses of control voltage impressed on the controllable resistance unit **54** correspond essentially to the curve s shown in the voltage-time diagram of Fig. 12. Fig. 12 also shows a curve i which exemplifies the current pulses in the load **51** assuming that the barrier diaphragm is always open. The phase position of the voltage curve s relative to the current curve i can be adjusted with the aid of the phase shifter **56**. The phase shifter **56** and/or the transformer **57** transform the voltage taken from the load circuit to be controlled so as to impress on the resistance unit a control voltage of the desired magnitude.

The operation of the device according to Fig. 11 can be explained as follows. If the resistance unit 54 in the circuit to be controlled were omitted, the positive half waves according to curve i in Fig. 11 would substantially fully pass through the load as is the case in conventional non-controllable rectifying apparatus. Due to the presence of the controlled resistance unit **54**, however, part of each positive current half wave can be cut off. The control voltage impressed upon the diaphragm electrode **55** through the circuit elements **56**, **57** and **58** has the effect that the barrier diaphragm is closed at some moment within the duration of the individual rectangular pulses of the curve s. As a result, the duration of current flow in the load circuit during the positive half waves of current curve i can be enlarged and diminished by adjusting the phase shifter **56**. In Fig. 12, the flow periods, i. e. the portions of the positive current half waves in which the current is effective in the circuit to be controlled, are marked by cross hatching. It will be recognized that by correspondingly displacing the curve s relative to curve i the current flow can be augmented up to the full value of the positive current half wave, and can be diminished to the zero value by a phase displacement in the opposite direction.

The series connection of a valve such as a dry rectifier with a controllable resistance unit of the type previously described thus results in controllable rectifying devices suitable for highly diversified applications similar to those heretofore served by gas-discharge devices, mercury-arc rectifiers, electronic tubes, etc. It will be obvious, therefore, that the control circuits applicable for the invention may be similar to those known from the techniques and applications of the just-mentioned other rectifying devices. In particular, many different circuits are known and suitable for providing an impulse sequence of rectangular, trapezoidal or the like wave shape similar to curve s in Fig. 12. For that reason, further details of the very many available circuit connections and arrangements need not here be given.

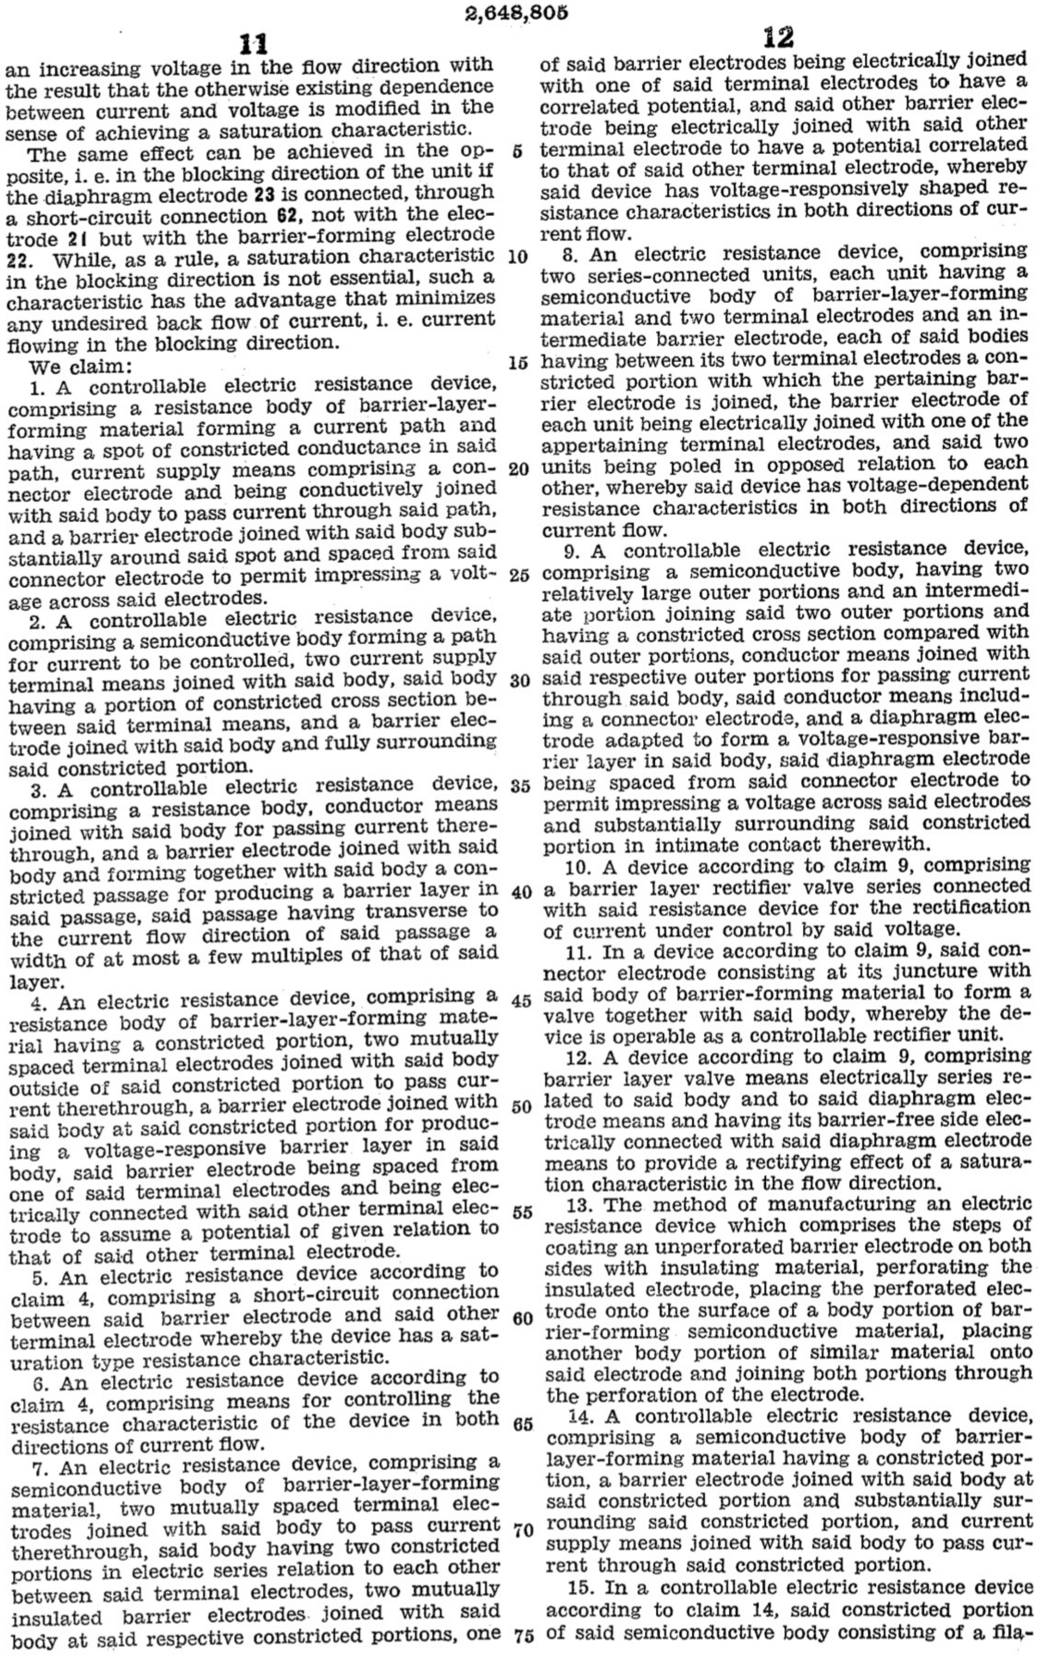
While in the above-described rectifying apparatus according to Fig. 11 the dry rectifier **53** and the series connected controllable resistance device **54** represent individual units, it is possible, and for many applications preferable, to join both devices into a single structural unit. Fig. 13 shows an embodiment of this type.

The device according to Fig. 13 involves a controllable resistance unit designed essentially in accordance with Figs. 3 and 4. In contrast, however, one of the connector electrodes, i. e. the electrode denoted in Fig. 13 by **22′** consists of a barrier-forming metal or alloy. For instance, when selenium is used as a barrier-susceptible material, the electrode **22′** may consist of a tin-cadmium alloy as used for the barrier electrode of conventional junction-type rectifier units. All other elements of the device shown in Fig. 13 are in accordance with Figs. 3 and 4 and denoted by similar respective reference numbers. In the unit according to Fig. 13, the two electrodes 22′ and **21** with the intermediate body **20** of semiconductive material may be looked upon as representing a conventional dry rectifier. By virtue of the inserted diaphragm electrode **23** with the appertaining slotted insulation **24**, a barrier diaphragm is inserted into this dry rectifier. Consequently, the unit of Fig. 13 as a whole functions in a manner similar to a series arrangement of a dry rectifier and a controllable barrier type resistance device. Hence, in circuits otherwise designed in accordance with Fig. 11, the unit of Fig. 13 may be used instead of the two circuit elements denoted in Fig. 11 by **53** and **54**.

The barrier layer diaphragm in a unit according to Fig. 13 may also be used not for the purpose of control in the sense of a steady or periodic control performance, but for imparting to the unit a saturation type characteristic, thus obtaining a rectifier with a saturating rectifying characteristic.

An embodiment of this type is illustrated in Fig. 14. The controllable unit as such is identical with that shown in Fig. 13 and has its elements denoted by the same respective reference numerals. However, according to Fig. 14, the two connector electrodes are attached to terminals **60** and **61** for connection to an alternating-current source or circuit. The diaphragm eletcrode 23 is connected through a short-circuit connection **62** with the connector electrode **21**. The performance of this arrangement will be understood if one considers that the flow direction of a valve or rectifier is from the connector electrode to the barrier electrode. With an increasing voltage in the flow direction, the current of an ordinary dry rectifier increases continuously with the voltage although not in a linear dependence. In apparatus according to Fig. 14, the flow area of the barrier diaphragm increases continuously with

Figure B.79: Frank Rose, Eberhard Spenke, and Erich Waldkötter filed detailed patent applications on transistors in 1949, likely based on wartime work.



an increasing voltage in the flow direction with the result that the otherwise existing dependence between current and voltage is modified in the sense of achieving a saturation characteristic.

The same effect can be achieved in the opposite, i. e. in the blocking direction of the unit if the diaphragm electrode **23** is connected, through a short-circuit connection **62**, not with the electrode **21** but with the barrier-forming electrode **22**. While, as a rule, a saturation characteristic in the blocking direction is not essential, such a characteristic has the advantage that minimizes any undesired back flow of current, i. e. current flowing in the blocking direction.

We claim:

1. A controllable electric resistance device, comprising a resistance body of barrier-layer-forming material forming a current path and having a spot of constricted conductance in said path, current supply means comprising a connector electrode and being conductively joined with said body to pass current through said path, and a barrier electrode joined with said body substantially around said spot and spaced from said connector electrode to permit impressing a voltage across said electrodes.

2. A controllable electric resistance device, comprising a semiconductive body forming a path for current to be controlled, two current supply terminal means joined with said body, said body having a portion of constricted cross section between said terminal means, and a barrier electrode joined with said body and fully surrounding said constricted portion.

3. A controllable electric resistance device, comprising a resistance body, conductor means joined with said body for passing current therethrough, and a barrier electrode joined with said body and forming together with said body a constricted passage for producing a barrier layer in said passage, said passage having transverse to the current flow direction of said passage a width of at most a few multiples of that of said layer.

4. An electric resistance device, comprising a resistance body of barrier-layer-forming material having a constricted portion, two mutually spaced terminal electrodes joined with said body outside of said constricted portion to pass current therethrough, a barrier electrode joined with said body at said constricted portion for producing a voltage-responsive barrier layer in said body, said barrier electrode being spaced from one of said terminal electrodes and being electrically connected with said other terminal electrode to assume a potential of given relation to that of said other terminal electrode.

5. An electric resistance device according to claim 4, comprising a short-circuit connection between said barrier electrode and said other terminal electrode whereby the device has a saturation type resistance characteristic.

6. An electric resistance device according to claim 4, comprising means for controlling the resistance characteristic of the device in both directions of current flow.

7. An electric resistance device, comprising a semiconductive body of barrier-layer-forming material, two mutually spaced terminal electrodes joined with said body to pass current therethrough, said body having two constricted portions in electric series relation to each other between said terminal electrodes, two mutually insulated barrier electrodes joined with said body at said respective constricted portions, one of said barrier electrodes being electrically joined with one of said terminal electrodes to have a correlated potential, and said other barrier electrode being electrically joined with said other terminal electrode to have a potential correlated to that of said other terminal electrode, whereby said device has voltage-responsively shaped resistance characteristics in both directions of current flow.

8. An electric resistance device, comprising two series-connected units, each unit having a semiconductive body of barrier-layer-forming material and two terminal electrodes and an intermediate barrier electrode, each of said bodies having between its two terminal electrodes a constricted portion with which the pertaining barrier electrode is joined, the barrier electrode of each unit being electrically joined with one of the appertaining terminal electrodes, and said two units being poled in opposed relation to each other, whereby said device has voltage-dependent resistance characteristics in both directions of current flow.

9. A controllable electric resistance device, comprising a semiconductive body, having two relatively large outer portions and an intermediate portion joining said two outer portions and having a constricted cross section compared with said outer portions, conductor means joined with said respective outer portions for passing current through said body, said conductor means including a connector electrode, and a diaphragm electrode adapted to form a voltage-responsive barrier layer in said body, said diaphragm electrode being spaced from said connector electrode to permit impressing a voltage across said electrodes and substantially surrounding said constricted portion in intimate contact therewith.

10. A device according to claim 9, comprising a barrier layer rectifier valve series connected with said resistance device for the rectification of current under control by said voltage.

11. In a device according to claim 9, said connector electrode consisting at its juncture with said body of barrier-forming material to form a valve together with said body, whereby the device is operable as a controllable rectifier unit.

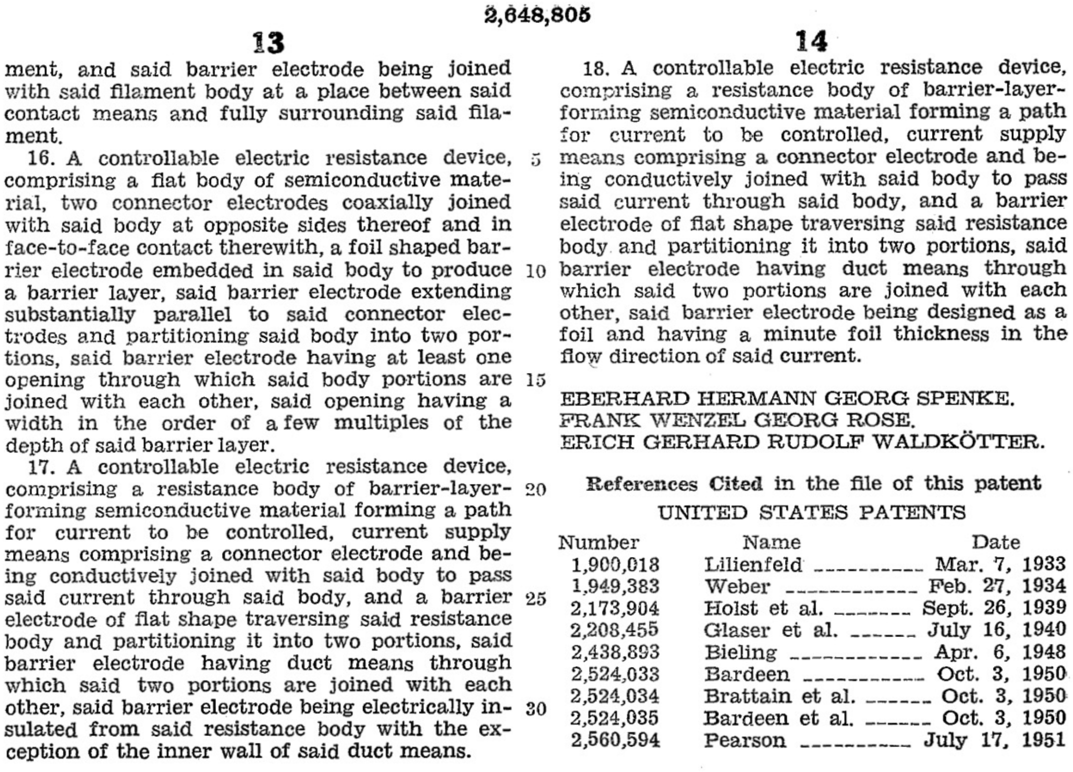
12. A device according to claim 9, comprising barrier layer valve means electrically series related to said body and to said diaphragm electrode means and having its barrier-free side electrically connected with said diaphragm electrode means to provide a rectifying effect of a saturation characteristic in the flow direction.

13. The method of manufacturing an electric resistance device which comprises the steps of coating an unperforated barrier electrode on both sides with insulating material, perforating the insulated electrode, placing the perforated electrode onto the surface of a body portion of barrier-forming semiconductive material, placing another body portion of similar material onto said electrode and joining both portions through the perforation of the electrode.

14. A controllable electric resistance device, comprising a semiconductive body of barrier-layer-forming material having a constricted portion, a barrier electrode joined with said body at said constricted portion and substantially surrounding said constricted portion, and current supply means joined with said body to pass current through said constricted portion.

15. In a controllable electric resistance device according to claim 14, said constricted portion of said semiconductive body consisting of a fila-

Figure B.80: Frank Rose, Eberhard Spenke, and Erich Waldkötter filed detailed patent applications on transistors in 1949, likely based on wartime work.



2,648,805

13

ment, and said barrier electrode being joined with said filament body at a place between said contact means and fully surrounding said filament.

16. A controllable electric resistance device, comprising a flat body of semiconductive material, two connector electrodes coaxially joined with said body at opposite sides thereof and in face-to-face contact therewith, a foil shaped barrier electrode embedded in said body to produce a barrier layer, said barrier electrode extending substantially parallel to said connector electrodes and partitioning said body into two portions, said barrier electrode having at least one opening through which said body portions are joined with each other, said opening having a width in the order of a few multiples of the depth of said barrier layer.

17. A controllable electric resistance device, comprising a resistance body of barrier-layer-forming semiconductive material forming a path for current to be controlled, current supply means comprising a connector electrode and being conductively joined with said body to pass said current through said body, and a barrier electrode of flat shape traversing said resistance body and partitioning it into two portions, said barrier electrode having duct means through which said two portions are joined with each other, said barrier electrode being electrically insulated from said resistance body with the exception of the inner wall of said duct means.

14

18. A controllable electric resistance device, comprising a resistance body of barrier-layer-forming semiconductive material forming a path for current to be controlled, current supply means comprising a connector electrode and being conductively joined with said body to pass said current through said body, and a barrier electrode of flat shape traversing said resistance body and partitioning it into two portions, said barrier electrode having duct means through which said two portions are joined with each other, said barrier electrode being designed as a foil and having a minute foil thickness in the flow direction of said current.

INTERVIEW AT HEIDENHEIM WITH PROF. DR. PAUL GUNTHER,
UNIVERSITY AND HOCHSCHULE OF BRESLAU,
ON SILICON CRYSTALS

(Target No. C-22/1326)

THIS PAGE IS DECLASSIFIED IAW EO 13526

Prof. Gunther's work was done in the Hochschule at Breslau under the direction of Major Rossler of the Germany Air Corps research organization. The crystals were used as detectors in ultra high frequency equipment.

According to his theory, the main difficulty with silicon crystals has been impurity. In general, the technique is the same as reported from interrogations of Dr. Bartels at Heidelberg and Dr. H. Rothe (Telefunken) at Dachau, but is reported here as received.

The carbon used was supplied by Siemens-Plania of Berlin, as "homogeneous" carbon made into rods 1.5 mm. in diameter and 6 mm. long from graphite powder. The rods are washed in nitric acid and piled like cordwood in a try within a tube so that only the two ends are coated with silicon to a thickness of .01 mm. and then broken in two making two detector units. In the same tube, about 12" long and 1.5" diameter is a vessel h very pure aluminum pellets. The cube is placed in a vacuum system and within an electric oven. At the far end of the system from the vacuum pump is a bulb of Si Cl4 kept in a cold container. Between the bute and the pump is a liquid air trap to keep Si Cl4 from reaching the pump and a mercury type shut-off valve.

In operation the oven is heated to 750°C and the system evacuated for ten to twenty minutes. When the pressure is down to 10^{-4} mm. and the Si Cl^{4} has purged the system of air, the temperature is held at between 720° and 950° for three to six hours. The temperature of the Si Cl4 normally rises from -20°C to -15°C and the pressure of the system is 40.mm. of mercury. The conditions give a super-saturated vapor of silicon which condenses on the carbon. The aluminum chloride apparently remains in the aluminum container although according to Dr. Bartels it condenses on the tube and acts as an indicator of the reaction.

Dr. Gunther disclaims knowledge of the mounting of these crystals and their electrical characteristics, but thinks molybdenum wirr contacts were used. Dr. Zeiler, also at Breslau Hochschule, worked on that problem. Nevertheless, he stated the best samples could stand up to 30 volts and the average worked well at 15 volts. At the "Nullpunkt widerstandt" the resistance was 50 ohms and at the "Bandwiderstandt" 30 ohms, the current ratios at these two points being 1:200. The crystals were considered good if when the voltage was 100 millivolts, the ratio of forward to reverse current was greater than five.

Gunther had also worked on Fe S_2 as a detector but found crystals of it variable. He had commenced an investigation to determine whether their detector action at high frequency breaks down because of chemical or physical changes.

Gunther was interested in work done at Munich by Heinrich Welker under Clusus on Germanium crystals. Using similar reactions and technique to those he had used with silicon, Gunther had found that the dual conductivity of the resulting crystals was caused by the presence of up to 20% of aluminum in the crystals. When he succeeded in getting good crystals, they were good detectors with resistances ranging from 15,000 to 20,000 ohms. The good crystals were obtained by exposing GE Cl_4 to a stream of H_2 at 700°C.

There seemed to be some evasiveness on the part of Dr. Gunther because when there were questions concerning the growing of quartz crystals, he did not mention the work of E. J. Chytrek of Breslau, one of his students who was experimenting with growing quartz crystals in a solution of sodium carbonate.

METHOD OF MAKING SURFACE-TYPE AND POINT-TYPE RECTIFIERS AND CRYSTAL-AMPLIFIER LAYERS FROM ELEMENTS

Karl Seiler, Nurnberg, Germany, assignor to International Standard Electric Corporation, New York, N. Y., a corporation of Delaware

Application April 5, 1950, Serial No. 154,064

Claims priority, application Germany April 6, 1949

4 Claims. (Cl. 117—106)

Unlike the large variety of point-type rectifiers (crystal diodes) there are only a few combinations of metals and semiconductors which exhibit a surface-type rectifying effect. Schottky's analysis of semiconductor rectification (see f. i. Zeitschrift für Physik, vol. 118, 1942, pp. 539–592) sets forth several reasons which may serve to clarify this fact.

(1) The relative impurity concentration throughout the semiconductor should be a minimum in the zone of increased resistance immediately adjacent the metallic electrode, in order to avoid short-circuits. Any increase in the number of impurities in this zone means great probability of short-circuits due to so-called by-passes.

(2) In the adjacent semi-conducting zone, however, adequate conductivity has to be provided by lattice-disturbing (impurity) atoms sufficient in number to greatly accentuate the zone mentioned in paragraph (1) where the so-called borderline effects take place.

To fulfil this requirement the disassociation level of the impurity atoms should be low (the impurity atoms should not diffuse readily), while the mobility of the electric carriers should be high. That only a few surface-type rectifications effects have been realized so far, derives from the fact that these two demands have not, or have hardly, been possible of fulfilment so far, for the known methods of making specified layer patterns are based exclusively on such processes where the space distribution of the impurities, is only obtained by modifications introduced by a secondary process by removing impurities at a suitable temperature, by chemical reaction (f. i. dissolving, lacquer-layers applied later on, etc.). Hence in making some specified layer pattern, the substances intended to produce the desired effects are placed at their respective locations in a first operation where no attention can be paid as to obtaining any specified space distribution of impurities, while that specified distribution, essential for proper performance, is brought about only subsequently in a second process governed by laws different from those of the first one. Thus one has been forced to simply accept as given whatever impurity concentration and distribution resulted from that second process without the possibility of introducing such corrective action of one's own as might be desirable to secure optimum distribution of impurities across the layer. With regard to the fact that very delicate arrangements are involved with layers present only as extremely thin films, it is obvious that the probability of inadequate results is rather large if these two essential processes are practiced one after the other.

In rectifiers involving compound-type semiconductors (in particular cuprous oxide) this fact is particularly pronounced as here the change in impurity concentration is caused by a chemical reaction which in turn is to introduce the stoichiometric unbalance of the semiconductor compound.

Generally a high impurity concentration is provided in the zones of the semiconductor more remote from the metallic electrode. But a certain maximum impurity concentration should not be exceeded in the zone of the semiconductor immediately adjacent the metallic electrode. This means that along the main direction of current flow the impurity concentration will have to obey a specified functional law, i. e. the dependence of the impurity concentration at a particular layer level will depend on the distance between that layer and the metallic electrode. This distance, however, is extremely small so it is obvious that rather erratic results are liable to occur in the few processes available for controlling the impurity concentration.

The drawbacks of the known methods are avoided in this invention by providing that the ultimate structure of the layer pattern is no longer obtained from two independent individual processes, but that the basic and the impurity substances are deposited simultaneously on the provided foundation, and that the specified relative impurity concentration is controlled to fit the needs of each particular layer while the layer is being built, so the desired space distribution of impurities is brought about.

It is known that the elements boron, silicon, germanium, and tellurium have semiconducting properties. In view of the delicacy of the processes to be controlled, the degree of chemical purity of the substances coated on the foundation electrode is of outstanding importance in making rectifiers.

In order to achieve uniform results and to control the porportion of the impurity admixture, it might seem desirable to vaporize the semiconductor materials and the impurity substances and deposit them from the vaporous state onto a suitable foundation. However, due to the high vaporizing temperatures of the materials involved there is induced the hazards of chemical reactions of the basic material or even the impurity contents with the material of the crucible which would produce uncontrolled and undesirable effects on the rectifying properties.

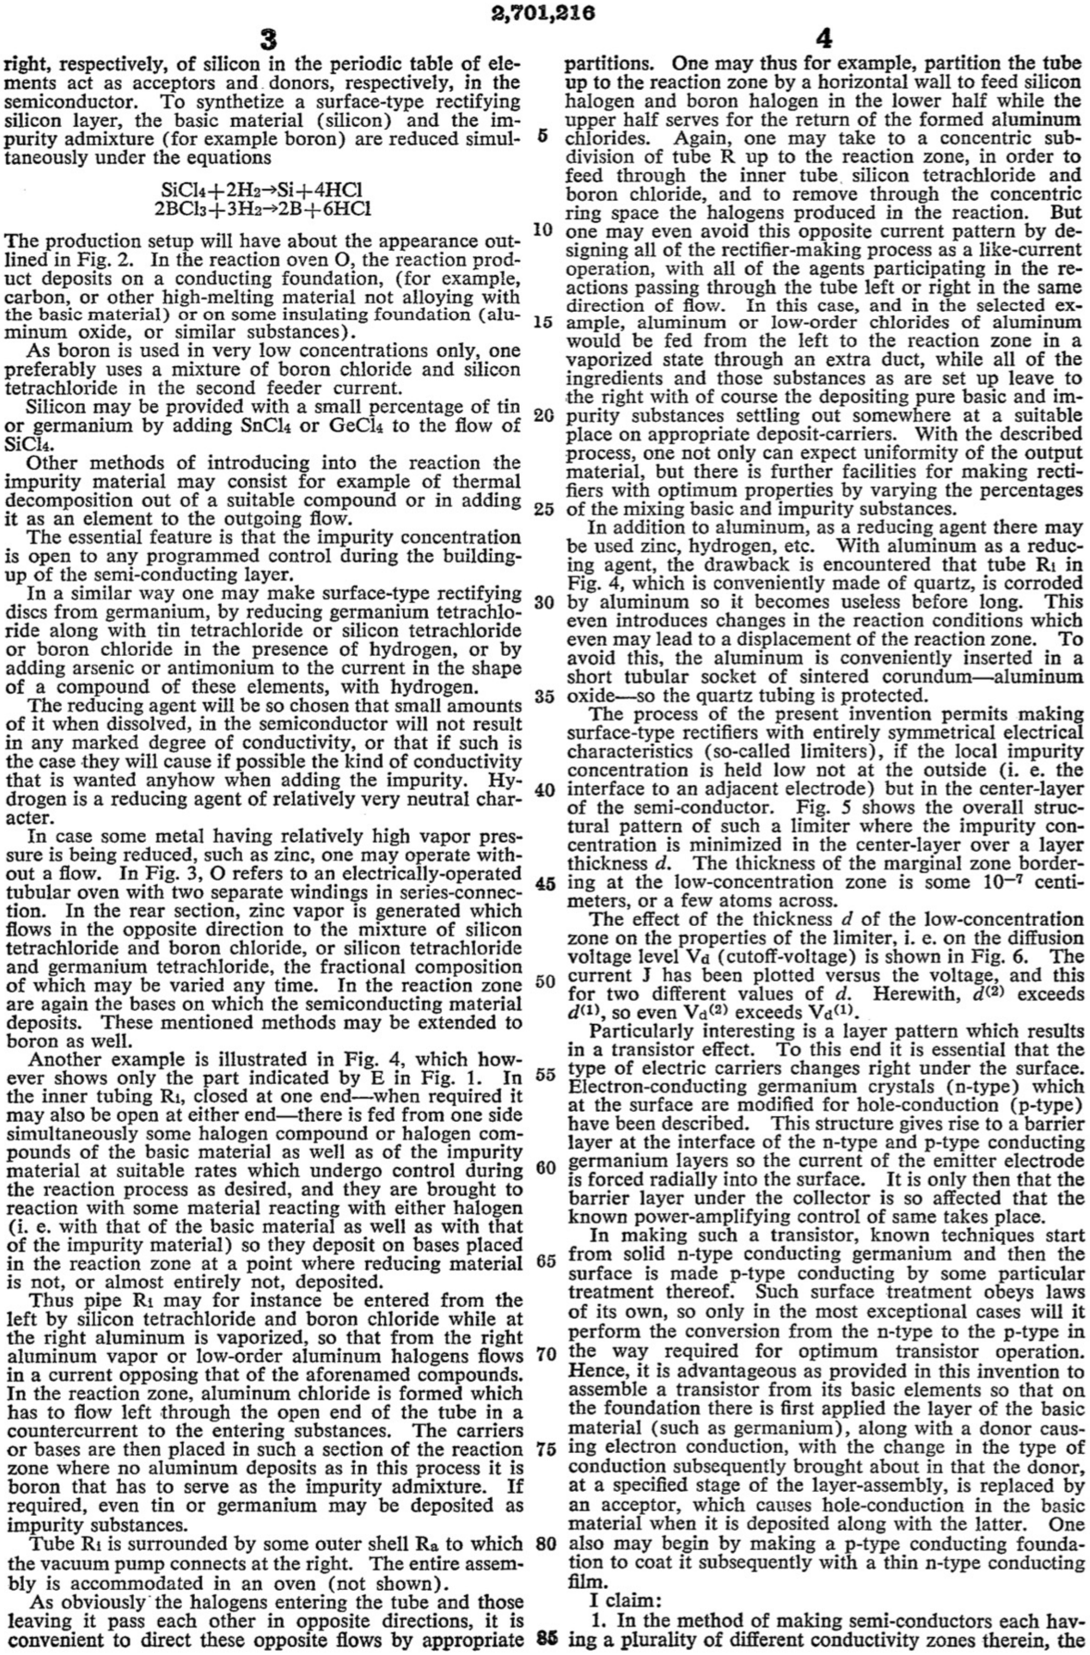
In order to avoid such high temperatures in production, one starts out in the known way from a liquid compound of the elements involved which by chemical rectification and customary chemical purifying methods can be prepared with a very high degree of purity and which in turn may be reduced chemically under proper conditions upon reaction with some equally pure reducing agent. Simultaneously with this reduction, the impurity substance may be treated in the same manner. With the relatively ample choice present in selecting admixtures to semiconducting elements, there is usually found some suitable chemical reaction mechanism which enables simultaneously synthesizing the impurity admixture. In a functional schematic, the nature of the process to be adopted is indicated in Fig. 1. A, B, C, and D refer schematically to devices where the substances needed for assembling the rectifying layer are obtained in their purest form by available processes according to what has been described above. As indicated schematically, these substances are then fed through pipes L_a, L_b, L_c, and L_d to the device E where the layer pattern is formed. In Fig. 1, these pipes L_a and L_b directly feed the device E with no prior intermixing of the substances being possible. Of course, one, two, or even all of the pipes could be joined in a common duct whenever intermixing of the substances is desired or permissible at such a relatively early stage of the production process. Equally in a schematic manner are shown control mechanisms R_a, R_b, R_c, and R_d at some arbitrary point along the ducts which allow any desired decrease or increase in the feeding rate of any of the ingredients while the semiconducting system is being built up. It is by no means essential that these controlling devices be inserted somewhere between the units A and E, B and E, etc., these controlling facilities may as well be incorporated straight in the units A, B, C, D or any additional units that might be present. Care will have to be taken, however, to prevent undesired reactions on the other devices B, C, D whenever at the junction of the pipes or individual pipe ducts the gas or vapor rate of device A is increased.

To practice this method, the elements boron, silicon, germanium, or tellurium may be used because of the high mobility of their electric carriers. To provide optimum efficiency, the impurity concentration at the back or counterelectrode is chosen large enough to prevent virtually any barrier layer from forming there.

As an example of the preparation of the semiconducting substance in building of a layer pattern, silicon may be reduced with hydrogen from silicon, tetrachloride or with zinc, in order to obtain pure silicon.

It is also known that the elements which are left and

Figure B.85: Karl Seiler and Paul Ludwig Günther designed and fabricated silicon electronic devices during the war, and filed patents on silicon transistors after the war (likely based on wartime work).



right, respectively, of silicon in the periodic table of elements act as acceptors and donors, respectively, in the semiconductor. To synthetize a surface-type rectifying silicon layer, the basic material (silicon) and the impurity admixture (for example boron) are reduced simultaneously under the equations

$$SiCl_4+2H_2\rightarrow Si+4HCl$$
$$2BCl_3+3H_2\rightarrow 2B+6HCl$$

The production setup will have about the appearance outlined in Fig. 2. In the reaction oven O, the reaction product deposits on a conducting foundation, (for example, carbon, or other high-melting material not alloying with the basic material) or on some insulating foundation (aluminum oxide, or similar substances).

As boron is used in very low concentrations only, one preferably uses a mixture of boron chloride and silicon tetrachloride in the second feeder current.

Silicon may be provided with a small percentage of tin or germanium by adding $SnCl_4$ or $GeCl_4$ to the flow of $SiCl_4$.

Other methods of introducing into the reaction the impurity material may consist for example of thermal decomposition out of a suitable compound or in adding it as an element to the outgoing flow.

The essential feature is that the impurity concentration is open to any programmed control during the building-up of the semi-conducting layer.

In a similar way one may make surface-type rectifying discs from germanium, by reducing germanium tetrachloride along with tin tetrachloride or silicon tetrachloride or boron chloride in the presence of hydrogen, or by adding arsenic or antimonium to the current in the shape of a compound of these elements, with hydrogen.

The reducing agent will be so chosen that small amounts of it when dissolved, in the semiconductor will not result in any marked degree of conductivity, or that if such is the case they will cause if possible the kind of conductivity that is wanted anyhow when adding the impurity. Hydrogen is a reducing agent of relatively very neutral character.

In case some metal having relatively high vapor pressure is being reduced, such as zinc, one may operate without a flow. In Fig. 3, O refers to an electrically-operated tubular oven with two separate windings in series-connection. In the rear section, zinc vapor is generated which flows in the opposite direction to the mixture of silicon tetrachloride and boron chloride, or silicon tetrachloride and germanium tetrachloride, the fractional composition of which may be varied any time. In the reaction zone are again the bases on which the semiconducting material deposits. These mentioned methods may be extended to boron as well.

Another example is illustrated in Fig. 4, which however shows only the part indicated by E in Fig. 1. In the inner tubing R_1, closed at one end—when required it may also be open at either end—there is fed from one side simultaneously some halogen compound or halogen compounds of the basic material as well as of the impurity material at suitable rates which undergo control during the reaction process as desired, and they are brought to reaction with some material reacting with either halogen (i. e. with that of the basic material as well as with that of the impurity material) so they deposit on bases placed in the reaction zone at a point where reducing material is not, or almost entirely not, deposited.

Thus pipe R_1 may for instance be entered from the left by silicon tetrachloride and boron chloride while at the right aluminum is vaporized, so that from the right aluminum vapor or low-order aluminum halogens flows in a current opposing that of the aforenamed compounds. In the reaction zone, aluminum chloride is formed which has to flow left through the open end of the tube in a countercurrent to the entering substances. The carriers or bases are then placed in such a section of the reaction zone where no aluminum deposits as in this process it is boron that has to serve as the impurity admixture. If required, even tin or germanium may be deposited as impurity substances.

Tube R_1 is surrounded by some outer shell R_a to which the vacuum pump connects at the right. The entire assembly is accommodated in an oven (not shown).

As obviously the halogens entering the tube and those leaving it pass each other in opposite directions, it is convenient to direct these opposite flows by appropriate partitions. One may thus for example, partition the tube up to the reaction zone by a horizontal wall to feed silicon halogen and boron halogen in the lower half while the upper half serves for the return of the formed aluminum chlorides. Again, one may take to a concentric subdivision of tube R up to the reaction zone, in order to feed through the inner tube silicon tetrachloride and boron chloride, and to remove through the concentric ring space the halogens produced in the reaction. But one may even avoid this opposite current pattern by designing all of the rectifier-making process as a like-current operation, with all of the agents participating in the reactions passing through the tube left or right in the same direction of flow. In this case, and in the selected example, aluminum or low-order chlorides of aluminum would be fed from the left to the reaction zone in a vaporized state through an extra duct, while all of the ingredients and those substances as are set up leave to the right with of course the depositing pure basic and impurity substances settling out somewhere at a suitable place on appropriate deposit-carriers. With the described process, one not only can expect uniformity of the output material, but there is further facilities for making rectifiers with optimum properties by varying the percentages of the mixing basic and impurity substances.

In addition to aluminum, as a reducing agent there may be used zinc, hydrogen, etc. With aluminum as a reducing agent, the drawback is encountered that tube R_1 in Fig. 4, which is conveniently made of quartz, is corroded by aluminum so it becomes useless before long. This even introduces changes in the reaction conditions which even may lead to a displacement of the reaction zone. To avoid this, the aluminum is conveniently inserted in a short tubular socket of sintered corundum—aluminum oxide—so the quartz tubing is protected.

The process of the present invention permits making surface-type rectifiers with entirely symmetrical electrical characteristics (so-called limiters), if the local impurity concentration is held low not at the outside (i. e. the interface to an adjacent electrode) but in the center-layer of the semi-conductor. Fig. 5 shows the overall structural pattern of such a limiter where the impurity concentration is minimized in the center-layer over a layer thickness *d*. The thickness of the marginal zone bordering at the low-concentration zone is some 10^{-7} centimeters, or a few atoms across.

The effect of the thickness *d* of the low-concentration zone on the properties of the limiter, i. e. on the diffusion voltage level V_d (cutoff-voltage) is shown in Fig. 6. The current J has been plotted versus the voltage, and this for two different values of *d*. Herewith, $d^{(2)}$ exceeds $d^{(1)}$, so even $V_d^{(2)}$ exceeds $V_d^{(1)}$.

Particularly interesting is a layer pattern which results in a transistor effect. To this end it is essential that the type of electric carriers changes right under the surface. Electron-conducting germanium crystals (n-type) which at the surface are modified for hole-conduction (p-type) have been described. This structure gives rise to a barrier layer at the interface of the n-type and p-type conducting germanium layers so the current of the emitter electrode is forced radially into the surface. It is only then that the barrier layer under the collector is so affected that the known power-amplifying control of same takes place.

In making such a transistor, known techniques start from solid n-type conducting germanium and then the surface is made p-type conducting by some particular treatment thereof. Such surface treatment obeys laws of its own, so only in the most exceptional cases will it perform the conversion from the n-type to the p-type in the way required for optimum transistor operation. Hence, it is advantageous as provided in this invention to assemble a transistor from its basic elements so that on the foundation there is first applied the layer of the basic material (such as germanium), along with a donor causing electron conduction, with the change in the type of conduction subsequently brought about in that the donor, at a specified stage of the layer-assembly, is replaced by an acceptor, which causes hole-conduction in the basic material when it is deposited along with the latter. One also may begin by making a p-type conducting foundation to coat it subsequently with a thin n-type conducting film.

I claim:

1. In the method of making semi-conductors each having a plurality of different conductivity zones therein, the

5

steps of simultaneously depositing from the vapor state onto a base material a semi-conducting substance commingled with an impurity substance selected from a group consisting of donor and acceptor impurities, and varying the proportion of said substances while applying them to the base in the form of a composite layer of said substances graduated in its cross-section as between amounts of the two substances applied.

2. Method according to claim 1, in which the semi-conducting substances are chosen from the group consisting of boron, silicon, germanium and tellurium.

3. Method according to claim 1, in which the highest amount of impurity substance is applied adjacent the base material.

4. Method according to claim 1, in which the lowest amount of impurity substance is placed in the center portion of the layer.

COMPOSITE ELECTRODES FOR DIRECTIONAL CRYSTAL DEVICES

Paul Günther and Franz Kerkhoff, Munich, Germany, assignors to Siemens & Halske Aktiengesellschaft, Munich, Germany, a corporation of Germany

Application February 1, 1954, Serial No. 407,196

Claims priority, application Germany February 27, 1953

11 Claims. (Cl. 317—235)

This invention is concerned with composite electrodes for directional devices comprising semi-conductors, for example, transistors and the like.

Composite electrodes for the purpose and of the type noted above are generally known. It is likewise known to form on such electrodes preferably point-shaped or knife-edge contacts of a hard core which is provided with a coating of another generally softer material, the latter being more suitable than the core material to form electrical contact engagement with a semi-conductor crystal. Such a known electrode may, for example comprise a tungsten wire plated with platinum. The drawback of such structure is that it is impossible to provide upon tungsten a sufficiently uniform platinum coating and that it is consequently impossible to produce such electrodes with the required uniformity in the course of customary mass production processes.

It has been found by research lying in back of the invention that the above mentioned drawbacks can be avoided by using other particular materials. In accordance with the invention, electrodes of the previously indicated type which comprise at least two different materials, for example, a core or carrier and a coating, are made of metals from the first, fourth, fifth and/or eight groups of the periodic table of elements. More specifically a hard material as for example niobium, tantalum, iron or alloys of such materials, for example, hard bronze of the type of phosphor-beryllium-bronze or the like may be used primarily for the core of the electrode; and for the coating may be used primarily materials of high output capacity, for example, rhodium, palladium, iridium, also platinum or, under some circumstances alloys of these materials. In the case of using in a transistor a plurality of electrodes, for example, two or three electrodes, the selection of the material for the surface coating will depend upon whether the electrode is to be employed as a collector or an emitter.

The invention will now be described with reference to the accompanying drawings showing in diagrammatic representation examples thereof. In these drawings,

Fig. 1 shows a germanium crystal coacting with a single point contact electrode; and

Fig. 2 illustrates a transistor comprising a germanium crystal coacting with two point contact electrodes.

In Fig. 1, numeral **1** indicates the germanium crystal. In contact engagement with the surface of the crystal is a point electrode comprising a wire **2** of phosphor-beryllium-bronze provided with a platinum coating **3**. The electrode is produced by providing upon the bronze wire, for example, in an alkaline ammonia phosphorous platinum bath of platinum coating in galvanic manner.

Fig. 2 shows a transistor comprising a germanium crystal **4** coacting with two point contact electrodes **5**

2

and **6**. Between the electrodes, a p-n layer is provided in a known manner. The electrode **5** is made like the electrode of Fig. 1, comprising a bronze core with a platinum coating **3**. The other electrode **6** comprises a steel core **7** covered by a copper coating **8**.

The coatings may be applied or provided in different manner than galvanic, for example, by vaporization, by cathode vaporization, or in mechanical manner, for example, by spraying or rolling. Burning such as is usually applied in the production of mirrors, ceramics, etc., is recommended for mass production.

What is believed to be new and desired to have protected is defined in the appended claims.

We claim:

1. A transistor comprising a crystal, in electrode in point contact with said crystal, said electrode including a core and a coating surrounding said core, said core formed from one or more metals of the group consisting of niobium, tantalum, iron, copper, tin, zinc, phosphorous, beryllium and alloys of the aforesaid metals, said coating formed from one or more metals of the group consisting of rhodium, palladium, iridium, platinum and alloys of the aforesaid metals, and said coating of said electrode in point contact with said crystal.

2. A transistor according to claim 1, wherein said core of the electrode comprises a hard bronze of the type of phosphor-beryllium-bronze.

3. A transistor according to claim 1, wherein said core of the electrode is formed of a hard bronze of the type of phosphor-beryllium-bronze, and said coating is formed of platinum.

4. A transistor comprising a crystal, at least two electrodes in point contact with said crystal, p-n layer provided in said crystal between the electrodes, one of said electrodes comprising a phosphor-beryllium-bronze core and a platinum coating, the other of said electrodes comprising a steel core and a copper coating, and said coatings of said electrodes in point contact with said crystal.

5. A composite electrode for a directional crystal device, said electrode provided with a point at one end for point contact with a crystal and comprising a core and a coating surrounding said core, said core formed from one or more materials of the group consisting of tantalum, phosphor-beryllium-bronze and steel, said coating formed from one or more materials of the group consisting of the elements of group eight of the periodic table of elements and consisting of rhodium, palladium, iridium and platinum.

6. A composite electrode according to claim 5, wherein said composite electrode may be used in a diode.

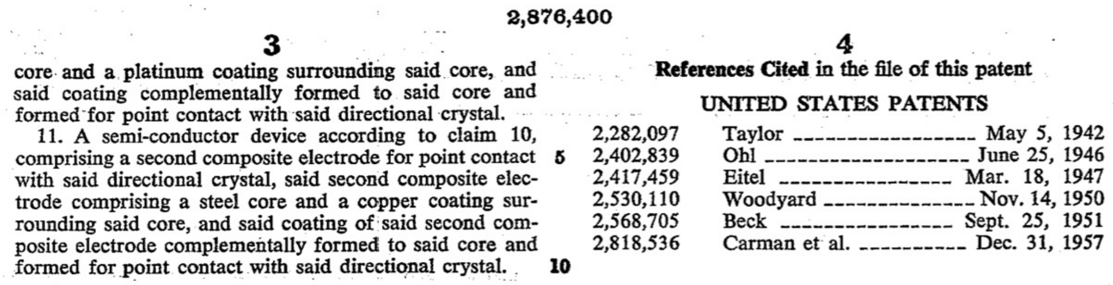
7. A composite electrode according to claim 5, wherein said composite electrode may be used as an emitter in a transistor.

8. A composite electrode for a directional crystal device said electrode formed with a point at one end for point contact with a crystal and comprising a steel core and a copper coating surrounding said core.

9. A composite electrode for use as a collector, said electrode comprising a core and a coating surrounding said core, said core formed from one or more materials of the group consisting of tantalum, phosphor-beryllium-bronze and steel, and said coating comprising one or more materials of the group consisting of copper and tin.

10. A semi-conductor device of the transistor type including a directional crystal, a composite electrode for point contact with said directional crystal, said composite electrode comprising a phosphor beryllium-bronze

Figure B.89: Karl Seiler and Paul Ludwig Günther designed and fabricated silicon electronic devices during the war, and filed patents on silicon transistors after the war (likely based on wartime work).



2,876,400

3

core and a platinum coating surrounding said core, and said coating complementally formed to said core and formed for point contact with said directional crystal.

11. A semi-conductor device according to claim 10, comprising a second composite electrode for point contact with said directional crystal, said second composite electrode comprising a steel core and a copper coating surrounding said core, and said coating of said second composite electrode complementally formed to said core and formed for point contact with said directional crystal.

[**11. Helmar Frank (Moravian, 1919–2015) and Jan Tauc (Bohemian, 1922–2010)** worked in very large, highly secret, German-run laboratories in Tannwald (now Tanvald, Czech Republic) during the war [Lojek 2007]. When Czechoslovakia salvaged what was left of those laboratories and restarted them after the war, one of the first actions that Frank and Tauc carried out was to produce and demonstrate transistors. Those postwar Czech transistors were based at least in part, and quite possibly entirely, on wartime German work. See for example:

pp. 1050–1072

pp. 2756–2757

p. 3983

p. 5503

p. 5513

p. 5549

Both Frank and Tauc continued to develop semiconductor and microelectronics technologies in Czechoslovakia for many years. Frank was interrogated by the United States in 1945 regarding his knowledge of advanced electronics technologies. Tauc eventually moved to the United States.

12. Bernhard Gudden (German, 1892–1945) and Kurt Lehovec (Bohemian/Austrian/Czech, 1918–2012) ran a secretive and well-funded group that was developing advanced semiconductor devices at Charles University in Prague during the war [Lojek 2007]. After the war, Gudden refused to assist Russian or Russian-backed forces and died in a Czech prison. Lehovec was extensively interrogated by the United States and then moved to the United States, where he filed patents on light emitting diodes, transistors, and integrated circuits. His first U.S. patent application on transistors covered a design that had several advantages over the transistors from Bell Laboratories, and that may well have been based on wartime work that he and Gudden had been conducting. See for example:

p. 1074

p. 1097

pp. 2757–2763

pp. 2818–2832

pp. 2895–2910

Historians should conduct much more archival research on the history and accomplishments of the wartime microelectronics programs at Bohemian/Moravian/Czech laboratories such as those where Helmar Frank, Jan Tauc, Bernhard Gudden, and Kurt Lehovec worked. Historians should also investigate the many ways that numerous countries benefitted after the war from scientists, information, and materials from those wartime programs.]

Czech National Library of Technology. Professor Helmar Frank. English translation. [https://www.techlib.cz/cs/84002-profesor-helmar-frank]

Helmar Frank was a Czechoslovak physicist of German nationality. He graduated in the Czechoslovak Republic and the Protectorate of Bohemia und Moravia, worked at the German University in Prague, the Institute of Physics of Charles University in Prague, the Research Institute of Communication Technology in Prague and since 1968 he worked as associate professor and later professor at the Faculty of Nuclear and Physical Engineering Technical University in Prague.

He created the first Czechoslovak semiconductor amplifying component—the point-contact germanium transistor—and developed, initiated and helped to introduce production of semiconductor materials and components in many Czechoslovak factories. [...]

1940–1942 scientific assistant at the Institute of Physics of the German University in Prague

1942–1945 lecturer Prof. Gudden at the Institute of Physics of the German University in Prague

1945–1947 detained by the Czechoslovak army in the framework of reparations

1947–1950 employed as a civil contract employee of the Military Technical Institute with a workplace in the Institute of Physics of Charles University

1950–1968 employed as an independent researcher at the Research Institute for Electro (tech) Physics. (VÚPEF, later VÚST)

1968–1983 Associate Professor, Department of Solid State Engineering, Faculty of Nuclear Sciences and Physical Engineering, Czech Technical University in Prague (KIPL FJFI ČVUT)

1972–1981 Head of the Department of Solid State Engineering

1973 appointed Chairman of the Board for the Defense of Candidate Dissertations, Chairman of the State Examination Board for the State Final Examinations, elected Vice-Dean for Science and Foreign Relations;

1983–2008 professor at FNSPE CTU

1950–2009 lectures and cooperation Faculty of Mathematics and Physics, Charles University in Prague, Technical University of Dresden, University of Regensburg, GSF Munich, Slovak Technical University in Bratislava, cooperation with CKD Semiconductors Prague, Tesla Vrchlabi, Prumet Sumperk, Tesla Roznov, Tesla Piestany

***Jan Tauc 1922–2010.* National Academy of Sciences 2011 [https://nas.nasonline.org/site/DocServer/Tauc_Jan.pdf]**

Jan's first job after graduation was at a government-supported research institute with a mission to develop electronic technologies (such as television and microwaves), using equipment and documentation left behind by the German army and declassified information from the West that became available after the war. The institute was located first in Tanvald, a mountainous region of northern Bohemia, which was the location of the former German army center. There Jan became involved in microwave detectors that the Germans had developed for the 10 cm wavelength band, using germanium. When the news of the invention of the transistor reached Prague, he used the germanium of those detectors to build the first point-contact transistor in Czechoslovakia and decided to stay in that field.

Bo Lojek. 2007. *History of Semiconductor Engineering.* Berlin: Springer. pp. 195–204.

Czech-born Kurt Lehovec started his career during World War II at Charles University in Prague as a Ph.D. student of Prof. B. Gudden (B. Gudden graduated and worked under Prof. Pohl). Kurt's Ph.D. study focused on lead-selenide as an infrared detector. During the course of this research, he noticed that Thallium diffused into Selenium very rapidly and the "blocking effect" of the rectifier was significantly improved. Süddeutsche Apparate Fabrik in Nüremberg supported Lehovec's study. This association let Lehovec attend a secret scientific conference about "Material X" in 1942 in Munich. The code name, Material X, was used for Germanium, and Lehovec did not know what Material X was.

German military research maintained two research groups working on semiconductors in occupied Czechoslovakian "Böhmen und Mähren" territory: The Prague group headed by Prof. B. Gudden worked on the rectifying diode; a second and larger group worked in the small town of Tanvald in the North of Bohemia on microwave point contact diode and radar research. Many members of the German research groups, including Prof. Gudden, were killed in May 1945 during the liberation of Czechoslovakia by the Red Army. A major part of the Tanvald research facility was confiscated by the Soviet army and transferred to the Soviet Union; the rest of the inventory was set on fire and destroyed.

Several kilograms of Germanium survived the fire and were used by Jan Tauc and Helmar Frank to build the first European [sic—actually the first Czech] transistors in 1949. Jan Tauc later immigrated to the United States. Helmar Frank, who was also a student of Prof. Gudden at Charles University, directed post-war semiconductor research sponsored by the Czechoslovakian Army at the former Philips Laboratories in Prague.

During the war the British Intelligence Assault Unit 30AU identified prominent scientists involved in German research. [...] At the end of the war, the CIA and KGB quickly joined the British effort and transferred several researchers from the Prague and Tanvald research groups to their respective countries. The CIA with U.S. Joint Intelligence Objectives Agency (JIOA) executed the Project Paperclip, and picked up Kurt Lehovec. Under very dramatic circumstances, when the Red Army began the liberation of Prague, and when hours not days made a difference, Lehovec peddled on a bicycle with his tennis racquet from Prague to the American occupied zone. Later, he was deported as a Paperclip item in a U.S. Navy ship to the Squier Laboratory at U.S. Signal Corps in Fort Monmouth in New Jersey.

The thinking behind project Paperclip was exemplified in a letter Major General Hugh Knerr, Deputy Commanding General for Administration of U.S. Strategic Forces in Europe, wrote to Lieutenant General Carl Spatz in [June] 1945: "*Occupation of German scientific and industrial establishments has revealed the fact that we have been alarmingly backward in many fields of research, if we do not take this opportunity to seize apparatus and the brains that developed it and put this combination back to work promptly, we will remain several years behind while we attempt to cover a field already exploited.*"

[...] Lehovec arrived at the U.S. Signal Corps with physical chemists, Dr. Rudolf Brill and Ernst Baers, physicists; Horst Kedesti, Georg Hass, Georg Goubau, Günter Guttwein, and electrical engineers; Hans Ziegler, Eduard Gerber, and Richard Guenther. From 210 Paperclip scientists the Signal Corps utilized 24 scientists, all involved in radar and communication research. The rocket scientists ended up in White Sands.

[...] In 1959, Ziegler became the Chief Scientist of U.S. Army Signal Corps' Laboratories at Fort Monmouth, N.J. After the Army's re-organization, he was appointed in 1963 to Deputy for Science and Chief Scientist of the US Army Electronics Command and in 1971 to Director of the U.S. Army Electronics Technology & Devices Laboratory. Dr. Ziegler was also a Fellow of the IEEE and the American Academy of Science. The Army recognized his achievements with two Meritorious—and the coveted Exceptional—Civil Service Awards. [...]

Lehovec asked the chief scientist of Squier Laboratory, Dr. Golay, what his research project should be, and he received the answer: "*you can do whatever you want, we need everything.*" Lehovec was one of the youngest members of the Paperclip team, and he worked very hard from day one. His group was assigned to the "Institute of Advanced Study" and had about 10 members. In 1948, Lehovec was sent to Purdue University to visit Prof. Lark-Horovitz's group to discuss ongoing research with the Signal Corps. With Dr. Harold A. Zahl, the Chief Scientist of the Signal Corps, Lehovec visited Bell Laboratories and started the Army's research on silicon and germanium devices, primarily on the problems of light emission from solids.

From his Prague studies he was familiar with the work of Russian scientist O. Lossew on "cold" light emission, first observed in silicon carbide in 1907. This effect, which was manifested by passing current through selected crystals of silicon carbide, showed a type of light emission which remained unexplained. Dr. Carl A. Accardo remembered when he was approached by Lehovec with an inquiry "*if I would be interested in studying the effects with him and his co-worker Edward Jamgochian.*" Their research indicated that the produced light was due to the recombination of electrons and holes across a so-called p-n junction. The two articles authored by Lehovec, Accardo and Jamgochian appeared in Physical Review and were presented at the American Physical Society in New York. The articles provided the theoretical background and an explanation of what later become known as LED's, or light emitting diodes.

Lehovec was a principal and reviewer of Semiconductor Research Contract DA36-0390SC 71131 between the U.S. Signal Corps and Prof. Karl Lark-Horovitz's group at Purdue University. During 1949–1950 Lark-Horovitz and R. Bray investigated the effect of strong electric fields on the observed spreading resistance of metal-germanium point-contact rectifiers. Some of these experiments closely resembled the work carried out simultaneously at Bell Telephone Laboratories by Bardeen, Brattain, and Shockley. [...]

Lehovec set up laboratory production in record time and he was on a mission. His goal was not to duplicate Bell Telephone Laboratories devices. He wanted to be an innovator, not a follower. He noticed already at the Signal Corps that the only drawback of the silicon devices was lower mobility of free carriers, which would make the devices somewhat slower compared to the germanium devices. Kurt Lehovec realized that the only way to overcome this disadvantage was to make the device smaller. However, to manufacture small devices in the beginning of the nineteen fifties was not an easy task. In addition, Sprague's management philosophy was, "*if this is any good, Bell would have done it already.*"

Lehovec found two basic problems with the Bell point contact transistor which the Sprague Company licensed:

1) Tedious labor to manipulate under a microscope two tiny wires to the correct position.

2) The possibility of sliding of the wires during the handling the device.

Lehovec came up with an ingenious solution to these problems which Armen Fermenian put into practice, a narrow sheet of beryllium copper was guided over a ceramic frame and glued to it. Two metal chisels cut the sheet within the frame providing the triangular shapes with sharp points facing to each other. A plunger then bent the tips of the triangles into vertical position at the desired spacing of the point contacts.

Lehovec visited Bell Labs and showed a transistor to Jack Morton. Morton was very impressed with Sprague technology and considered an order of a large number of devices for Western Electric. The deal was, however, aborted by Sprague management. The next major improvement of transistor technology was the introduction of new “capillary alloying” for junction transistor. This method allowed to calculate the amount of germanium dissolved in the indium from the germanium-indium phase diagram at the given temperature, and thus to control the junction depth. In addition, the surface-melt technique enabled the production of multiple junctions in a single slice of semiconductor. The method was superior to the BTL and TI grown-junction transistor process, which could produce only PNP or NPN structures. [...]

Another of Lehovec’s major inventions, junction isolation, had a very interesting background. Lehovec attended a workshop at Princeton University in the end of 1958. Torkel Wallmark of RCA presented in this workshop a visionary presentation about the next generation of electronics. Wallmark listed problems that needed to be solved before integrated circuits could be designed. One of these limitations was device isolation. Lehovec, educated from his work on the surface-melt multiple-junction devices found a solution while driving his red Corvette—PN junction isolation.

The engineering problem was solved; the bigger problem remained to be overcome. At that time nobody had heard anything about integrated circuits, so only visionaries could have appreciated the importance of Lehovec’s invention. The Sprague Company did not have visionaries and they did not want to file a patent application. Sprague’s patent attorney, Hillary Sweeney, explained at great length to Lehovec, that a patent needed to have a docket number and must be in sequence with previous disclosures, and that he was too busy to do it. Lehovec wrote the patent application himself and mailed it to the Patent Office. After months, a persistent Lehovec finally prevailed. His patent was approved and issued by the Patent Office without a major objection. Immediately after the patent 3,029,3662 was issued, Al Bower, of the patent firm Connolly & Hutz that handled the Sprague patents, called Lehovec that Texas Instruments is suing Sprague for patent interference. [...]

Texas Instruments set up the interference proceeding hearing in a large conference room and equipped Kilby with double digits of TI’s attorneys. Sprague Company was represented by Attorney at Law, Mr. Hutz, and Kurt Lehovec. [...]

The whole Texas Instruments séance ended as a complete debacle, and attorney Hutz was asked to deliver a written summary of arguments presented at the hearing. Three weeks later the U.S. Patent Office decided that Lehovec was entitled to all patent claims and was awarded patent priority.

Harold Zahl, a retired Director of the U.S. Army's Fort Monmouth laboratory [Zahl 1968, pp. 108–109]

On "Project Paperclip" it was not pieces of equipment or missiles which were brought over from Germany, it was people—scientists, engineers, and families. In the cruel years immediately following the war there were many very able scientists and engineers who wished to leave Western Europe and make a new home in the United States.

"Screening" offices were accordingly set up in Europe, and applications studied very carefully as to ability and previous political interests. Simultaneously military laboratories in this country were asked whether they wished any of these people, and their dossiers were made available for decision purposes.

As most elsewhere, at Monmouth we had two problems: First, the war still remained very fresh in the memories of our people; and second, we were still releasing relatively unskilled American citizens. But the superb talent available through "Paperclip" suggested once-in-a-lifetime opportunities, and much of the top American talent was straining to get out of the military environment back to their teaching jobs or to industry.

Demonstrative of the type of talent we were dealing with, on each request the requester had to sign a statement to the effect that the equivalent to the person he was asking for was not available in the U.S. The problem of asking for this type of talent, or rather the decision as to whether we should, was put squarely up to me as director of research. I recommended "Yes, let's try it with 25 people," and we were in business. This was probably one of the most important decisions I have ever made.

The men and their families then started coming over, most of them with all their worldly possessions and hardly any money. The title of "Doctor" soon grew commonplace at Monmouth. In coming over, they were signed for a two-year contract, with our option to return them in six months if we for any reason found them unsatisfactory. After the contract expired, Civil Service regulations allowed them to change to what was called Schedule-A, a form of Civil Service which would be finalized once citizenship had been achieved.

I have in my office a photo of the first 16 which came over, hands up, swearing allegiance to the United States, as they moved into Schedule-A. Of these 16, now twenty years later, 11 still remain at the Monmouth laboratory, all in very high positions, and one in the very highest. It was a wonderful experience to see the old "Melting Pot" in action.

In retrospect, throughout the country we see thousands of our best citizens, able engineers, scientists, and administrators, with a byproduct of tens of thousands of brilliant children in our schools . . . the results of "Paperclip." Surely this country is better and stronger because of that decision, made by a few men more than two decades ago.

TRANSISTOR POINT CONTACT ARRANGEMENT

Kurt Lehovec, Williamstown, Mass., assignor to Sprague Electric Company, North Adams, Mass., a corporation of Massachusetts

Application December 31, 1952, Serial No. 328,948

6 Claims. (Cl. 317—235)

The present invention relates to new and improved point contact constructions for transistors.

The field of transistors is now so well known that it is not deemed necessary to devote any of the present specification to purely descriptive matter relating to this subject. In this connection, reference is made to the text "Holes and electrons in semiconductors" by Schockley, the entire November 1952 issue of the Proceedings of the Institute of Radio Engineers, as well as other publications.

One type of transistor which presently shows a great deal of promise requires the use of two point contacts termed the emitter and the collector bearing against a single crystal of a metal such as germanium, silicon, or other related semiconducting materials. A third low resistance electrical connection is made to such a crystal. In order to obtain satisfactory operating characteristics with this type of construction the two point contacts must be positioned relatively close, and must remain in a comparatively fixed position.

It is now a common procedure to hold these point contacts or probes in place by the use of a small amount of tension and a stiff gel-like filler material. Other means for accomplishing the same result have been suggested. These include the use of stiff fabric-like inserts through which the probes are inserted; the use of an adjacent wall upon which the point contacts are mounted; and other means. The number of suggestions made on the subject of positioning wire probes in itself indicates the ineffectiveness of the presently used procedures.

An object of the present invention is to improve upon the aforegoing and related methods for positioning wire point contacts against a body of a semiconducting material used in a transistor. A further object is to produce new and improved transistor constructions. These and other aims of the invention, as well as the advantages of it will be apparent from the following description and claims, as well as the accompanying drawings in which:

Figure 1 diagrammatically illustrates a transistor formed in accordance with this disclosure; and

Figure 2 is a diagrammatic view of a modified construction of the invention; and

Figure 3 is a diagrammatic view of a still further modified construction. In all figures like numerals designate like parts.

In Figure 1 of the drawings a simple transistor construction is shown in which a small semiconducting wafer **11** such as, for example, a germanium crystal about 30 x 50 x 150 mils in size is provided with two apertures **12** through which wire probes **14** project. Each of these probes **14** is insulated from the wafer **11** by an insulating sleeve **13** of polyethylene or the like, and is bent so that the point contacts **15** touch the same face of the crystal quite close to one another. Preferably a space of from 1 to 5 mils separates them. A low resistance contact **16** of known type is made to the wafer **11** through the wire **17**.

The modification shown in Figure 2 of the drawing

2

differs from the construction of Figure 1 solely in that the adjacent point contacts **15** are positioned upon opposite sides of a wall **21** in small cavities **22** formed within the wafer **11**. Preferably, this wall **21** should be from about 1 to about 5 mils thick. The construction shown in this figure has the advantage that with it the point contacts are not apt to be dislodged due to handling, as when encasing the entire unit in a protective insulating resin.

The same advantage is derived from the construction illustrated in Figure 3. Here the wire probes **14** are inserted through the holes **12** in the wafer **11** from opposite directions so that the point contacts **15** project towards one another within the cavities **32**, but are separated by the wall **31** which is preferably of the thickness previously indicated.

The various apertures and holes or cavities herein indicated can be found in a variety of methods known to the art, such as, for example, by the use of dental abrasive equipment.

The herein described invention has a number of advantages. Perhaps one of the most important of these is comparative ease with which it adapts itself to large scale production techniques. By one procedure a comparatively large flat body of a semiconductor can be provided with the apertures, holes, and/or cavities for a large number of transistors at the same time, the appropriate connections and probes indicated can be placed in position, and then the individual transistors actually formed by cutting the larger body. If desired, the initial block can be scored or perforated so as to assist in separating the individual units. Various known steps, not specifically indicated herein, such as, for example, etching can be carried out at any convenient stage in forming the units of the invention. Also, a construction similar to that shown in Figure 1 can be formed utilizing a very thin wafer with the point contacts positioned upon opposite sides of it in the broad manner indicated.

As many apparently widely different embodiments of this invention may be made without departing from the spirit and scope hereof, it is to be understood that the invention is not limited to the specific embodiments hereof except as defined in the appended claims.

What is claimed is:

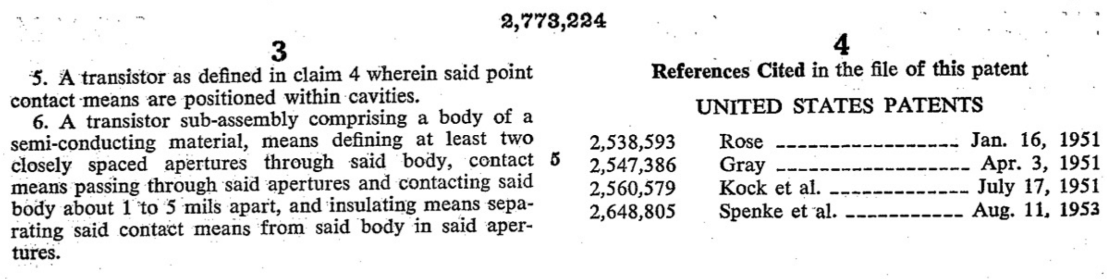
1. A transistor comprising a body of a semiconducting material, means defining at least two closely-spaced apertures through said body, wire probe means passing through said apertures, insulating means separating said wire means from said body in said apertures, point contact means formed on the tips of said probe means, said point contact means forming rectifying contacts with parts of said body about 1 to 5 mils apart.

2. A transistor as defined in claim 1 wherein said contacts are both on the same face of said body.

3. A transistor comprising a body of a semiconducting material, means defining at least two closely-spaced apertures in said body, wire probe means passing through said apertures, insulating means separating said wire means from said body in said apertures, point contact means formed on the tips of said probe means and positioned within cavities upon the same face of said body, said point contact means forming rectifying contacts with adjacent parts of said body.

4. A transistor comprising a body of a semiconducting material, means defining at least two closely-spaced apertures in said body, wire probe means passing through said apertures, insulating means separating said wire means from said body in said apertures, point contact means formed on the tips of said probe means positioned upon opposed sides of said body, said point contact means forming rectifying contacts with adjacent parts of said body.

Figure B.92: Kurt Lehovec developed semiconductor devices for Germany during the war. After the war he was extensively interrogated by the United States and then moved to the United States, where he filed patents on light emitting diodes, transistors, and integrated circuits. In 1952, he filed a patent application on a transistor design that had several advantages over the transistors from Bell Laboratories.



2,773,224

3

5. A transistor as defined in claim 4 wherein said point contact means are positioned within cavities.

6. A transistor sub-assembly comprising a body of a semi-conducting material, means defining at least two closely spaced apertures through said body, contact means passing through said apertures and contacting said body about 1 to 5 mils apart, and insulating means separating said contact means from said body in said apertures.

B.2 Printed Circuits and Multi-Pin Connectors

[While moving from large vacuum tubes to small transistors greatly helped to miniaturize and simplify electronics, the development of printed circuit boards was another major step in microelectronics. In printed circuits, electronic components are attached to an insulating board that is covered with etched metal lines for wires, avoiding the labor and bulkiness involved in connecting separate physical wires to each component. A closely related technological development was multipin connectors, which could be used without printed circuits but became even more advantageous when used together with printed circuits.

As shown on pp. 2766–2777, Albert Hanson (German, 18??–19??) filed patent applications on printed circuits and multi-pin connectors in 1902 and 1903. From the available documentation, it is not clear how far he got in implementing his designs, although the highly detailed nature of the patents suggests that he may well have built and tested printed circuits and multi-pin connectors.

Mathias Nowottnick, an engineering professor at the University of Rostock, noted that printed circuit technology, apparently based on Hanson's patents, was being used by at least three German companies by 1927–1932 [Nowottnick 2014, p. 4]:

1927 Telefunken, Verdrahtung von Bauteilen mittels Messingstreifen.	1927 Telefunken, wiring of components using brass strips.
1930 Hescho-Werke in Hermsdorf Aufdrucken von Leiterzügen auf Keramiksubstrat mittels Siebdrucktechnik (stellt heute noch die Grundlage für die Dickschichttechnik dar!)—"Gedruckte Schaltung".	1930 Hescho Works in Hermsdorf Imprinting of conductors on ceramic substrate using screen printing technology (still the basis for thick-film technology today!)—"printed circuits."
1932 erste Leiterplatte mit genieteten Metallstreifen, Sachsenwerk Licht und Kraft AG [Fig. B.106]	1932 first printed circuit board with riveted metal strips, Sachsenwerk Light and Power AG [Fig. B.106]

Wolfgang Scheel, a longtime department head of the Fraunhofer Institute, named additional German companies that were among the first to use printed circuits [Manfred Frank 2003, p. 2]:

Lassen Sie mich zunächst feststellen, dass die Leiterplatte in diesem Jahr [2003] ihren 100. Geburtstag feiert. Der Berliner Hanson hat dafür das Patent 1903 angemeldet. Ferner möchte ich anmerken, dass als Pionierfirmen auf dem Gebiet der Leiterplattenentwicklung in Deutschland die Sachsenwerk Licht und Kraft AG Niedersedlitz, die Ruwelwerke Geldern, die Lackwerke Peters in Kempen und die Isola AG in Düren zu nennen sind.	Let me first note that the printed circuit board celebrates its 100th birthday this year [2003]. Hanson from Berlin filed the patent for it in 1903. I would also like to note that the pioneering companies in the field of printed circuit board development in Germany are Sachsenwerk Licht und Kraft AG Niedersedlitz, Ruwelwerke Geldern, Lackwerke Peters in Kempen and Isola AG in Düren.

Paul Eisler (Austrian, 1907–1992) studied engineering at the University of Vienna, graduated in

1930, and worked in electrical engineering, during which time he apparently became familiar with then-current German and Austrian printed circuit technologies that were based on Hanson's original patents. In 1936 Eisler fled to the United Kingdom, taking his knowledge of printed circuit technologies with him, and he immediately began building printed circuits upon his arrival there [Eisler 1989; Medawar and Pyke 2000].[4]

Eisler brought printed circuit technology to the attention of the British government during World War II and filed patent applications on it in 1944 (pp. 2779–2795). Some U.S. officials discovered Eisler's work and incorporated simple printed circuits into proximity fuses for artillery shells that were used in late 1944 and 1945, but otherwise Allied countries do not seem to have harnessed the potential of printed circuits during the war.

In contrast, as shown on pp. 2796–2799, printed circuits were in "wide use" in wartime Germany (apparently having grown far beyond just Telefunken, Hescho-Werke, and Sachsenwerk since ~1930), and all of that printed circuit technology was transferred to the United States on a large scale after the war by people such as longtime Bell Telephone Laboratories engineer Todos Odarenko.

The final step in the development of printed circuits came when Rudolf Strauss (German, 1913–2001) developed the wave soldering method for the fully automated manufacturing of printed circuits, or surface mount technology (SMT), from 1951 to 1955; see pp. 2800–2806 [rondinax.wordpress.com/2014/01/31/rudolf-strauss-1913-2001-a-key-player-in-the-rondinax-and-rondix-story/]. (Was Strauss truly the original creator of wave soldering, or did he bring that method with him from the German-speaking world, just as Eisler apparently brought printed circuits?)

Boris Chertok, who led some of the Soviet missions removing German technologies after World War II, mentioned the widespread German use of sophisticated multi-pin connectors. Those likely went along with printed circuits, since printed circuits were in wide use and both multi-pin connectors and printed circuits traced back to Albert Hanson's inventions. Chertok also described the transfer of many other advanced electronics technologies to the Soviet Union (pp. 2807–2812).

The figure on p. 2813 shows a panel of multi-pin connectors from an A-4 (V-2) rocket produced during the war [Peenemünde Archive, Folder ARK 41].

Much more archival research is needed to reconstruct the detailed history and extent of research and development of printed circuits in the German-speaking world, as well as how that work was transferred to other countries during and after the Third Reich.]

---

[4] Note that many historians have described Eisler as the inventor of printed circuits. While Eisler played a critical role in transferring printed circuit technology out of the German-speaking world and producing the first printed circuits in Allied countries, it seems clear from the historical record that Albert Hanson was the original inventor in 1902, and that multiple companies in the German-speaking world were building and selling printed circuits several years before Eisler ever built his first printed circuit board. From both his studies and his work as an electrical engineer, presumably he would have been familiar with those technologies before he left the German-speaking world.

Accepted, 7th Oct., 1904

COMPLETE SPECIFICATION.

Improvements in Automatic Switchboards for Telephone and like Exchanges.

I, ALBERT PARKER HANSON, of 6 Lützow, Charlottenburg, in the Kingdom of Prussia, Engineer, do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:—

My invention relates to the construction and disposition of apparatus in automatic exchanges, that is, centrals in which a number of selective switches, worked from a distance, are installed. Such plants are for example employed in so-called "automatic" telephone service. A single selective mechanism proper of such a plant with its box or frame will be called here the "switch", while the imaginably closed bounded field within which the lines leading to or past the switch are made accessible for purposes of making contact will be called a "contact field". A bank of contacts is a number of conducting bodies so arranged and held together as to present a contact field to the switch.

The purpose of my invention is to provide methods by which simplicity in manufacture, ease of transport and installation, accessibility in operation, facility in handling in service and economical use of space are insured.

These advantages I secure singly or in various combinations by incorporating numbers of contact banks into more or less rigid rows, independently of the switches to which they belong, and providing for their advantageous disposition at the central.

A very important feature of the invention is its allowing of many and varied forms each bringing with it a series of practical arrangements. Thus, in the forms hereinafter described in illustration of the invention, the advantages above enumerated are secured in an advancing degree even while the cost of manufacture per unit of apparatus is constantly decreasing.

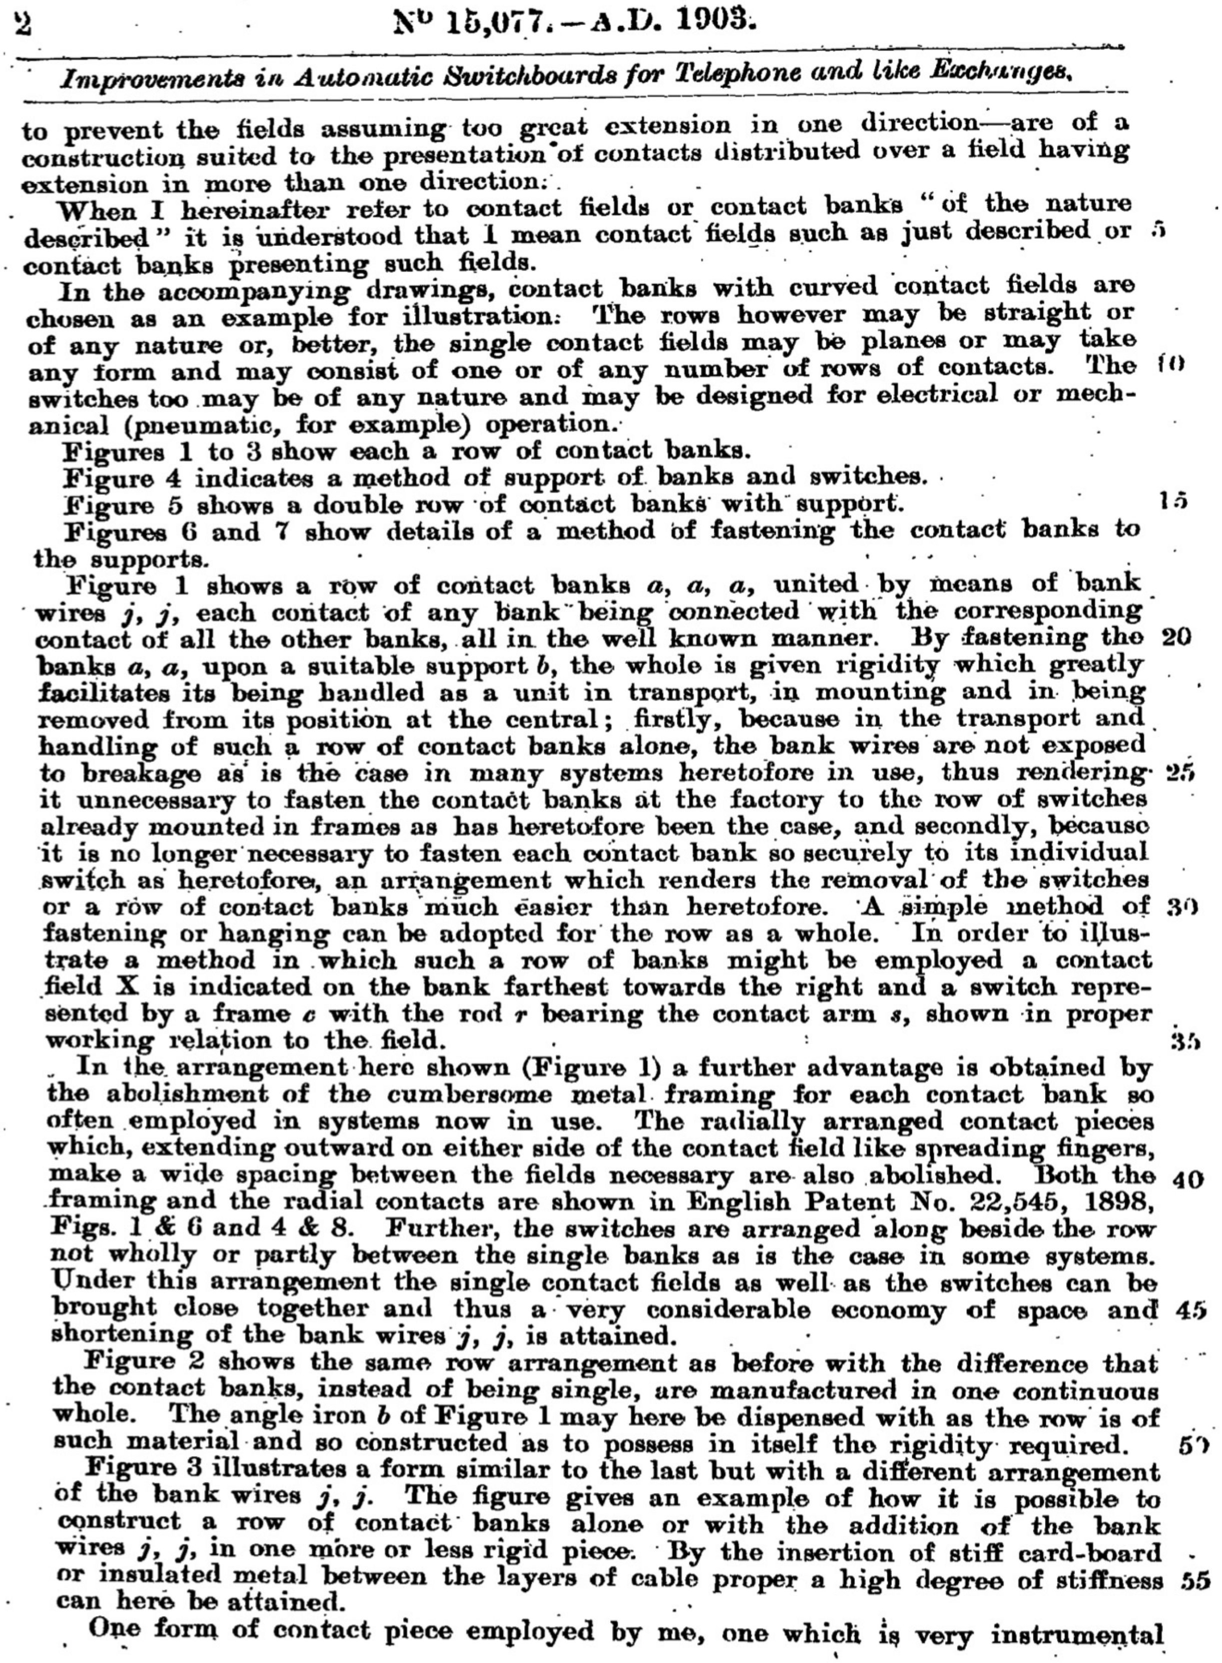
Arrangements of wires or other conductors running parallel to each other, practically like zither-strings, and forming contact fields for switches arranged in a row parallel to them are already known—see British Patents, No. 8607/'94 and 23239/'97, also U.S. Patent No. 626983, Decker Fig. 15.

My invention, however, is not affected by these and similar arrangements as heretofore applied. The contact banks employed by me are such as—in order

[*Price 8d.*]

BIRMINGHAM FREE LIBRARIES.

Figure B.94: Albert Hanson filed detailed patent applications on printed circuits and multi-pin connectors in 1902–1903.



2 Nº 15,077.—A.D. 1903.

Improvements in Automatic Switchboards for Telephone and like Exchanges.

to prevent the fields assuming too great extension in one direction—are of a construction suited to the presentation of contacts distributed over a field having extension in more than one direction.

When I hereinafter refer to contact fields or contact banks "of the nature described" it is understood that I mean contact fields such as just described or contact banks presenting such fields.

In the accompanying drawings, contact banks with curved contact fields are chosen as an example for illustration. The rows however may be straight or of any nature or, better, the single contact fields may be planes or may take any form and may consist of one or of any number of rows of contacts. The switches too may be of any nature and may be designed for electrical or mechanical (pneumatic, for example) operation.

Figures 1 to 3 show each a row of contact banks.

Figure 4 indicates a method of support of banks and switches.

Figure 5 shows a double row of contact banks with support.

Figures 6 and 7 show details of a method of fastening the contact banks to the supports.

Figure 1 shows a row of contact banks *a*, *a*, *a*, united by means of bank wires *j*, *j*, each contact of any bank being connected with the corresponding contact of all the other banks, all in the well known manner. By fastening the banks *a*, *a*, upon a suitable support *b*, the whole is given rigidity which greatly facilitates its being handled as a unit in transport, in mounting and in being removed from its position at the central; firstly, because in the transport and handling of such a row of contact banks alone, the bank wires are not exposed to breakage as is the case in many systems heretofore in use, thus rendering it unnecessary to fasten the contact banks at the factory to the row of switches already mounted in frames as has heretofore been the case, and secondly, because it is no longer necessary to fasten each contact bank so securely to its individual switch as heretofore, an arrangement which renders the removal of the switches or a row of contact banks much easier than heretofore. A simple method of fastening or hanging can be adopted for the row as a whole. In order to illustrate a method in which such a row of banks might be employed a contact field X is indicated on the bank farthest towards the right and a switch represented by a frame *c* with the rod *r* bearing the contact arm *s*, shown in proper working relation to the field.

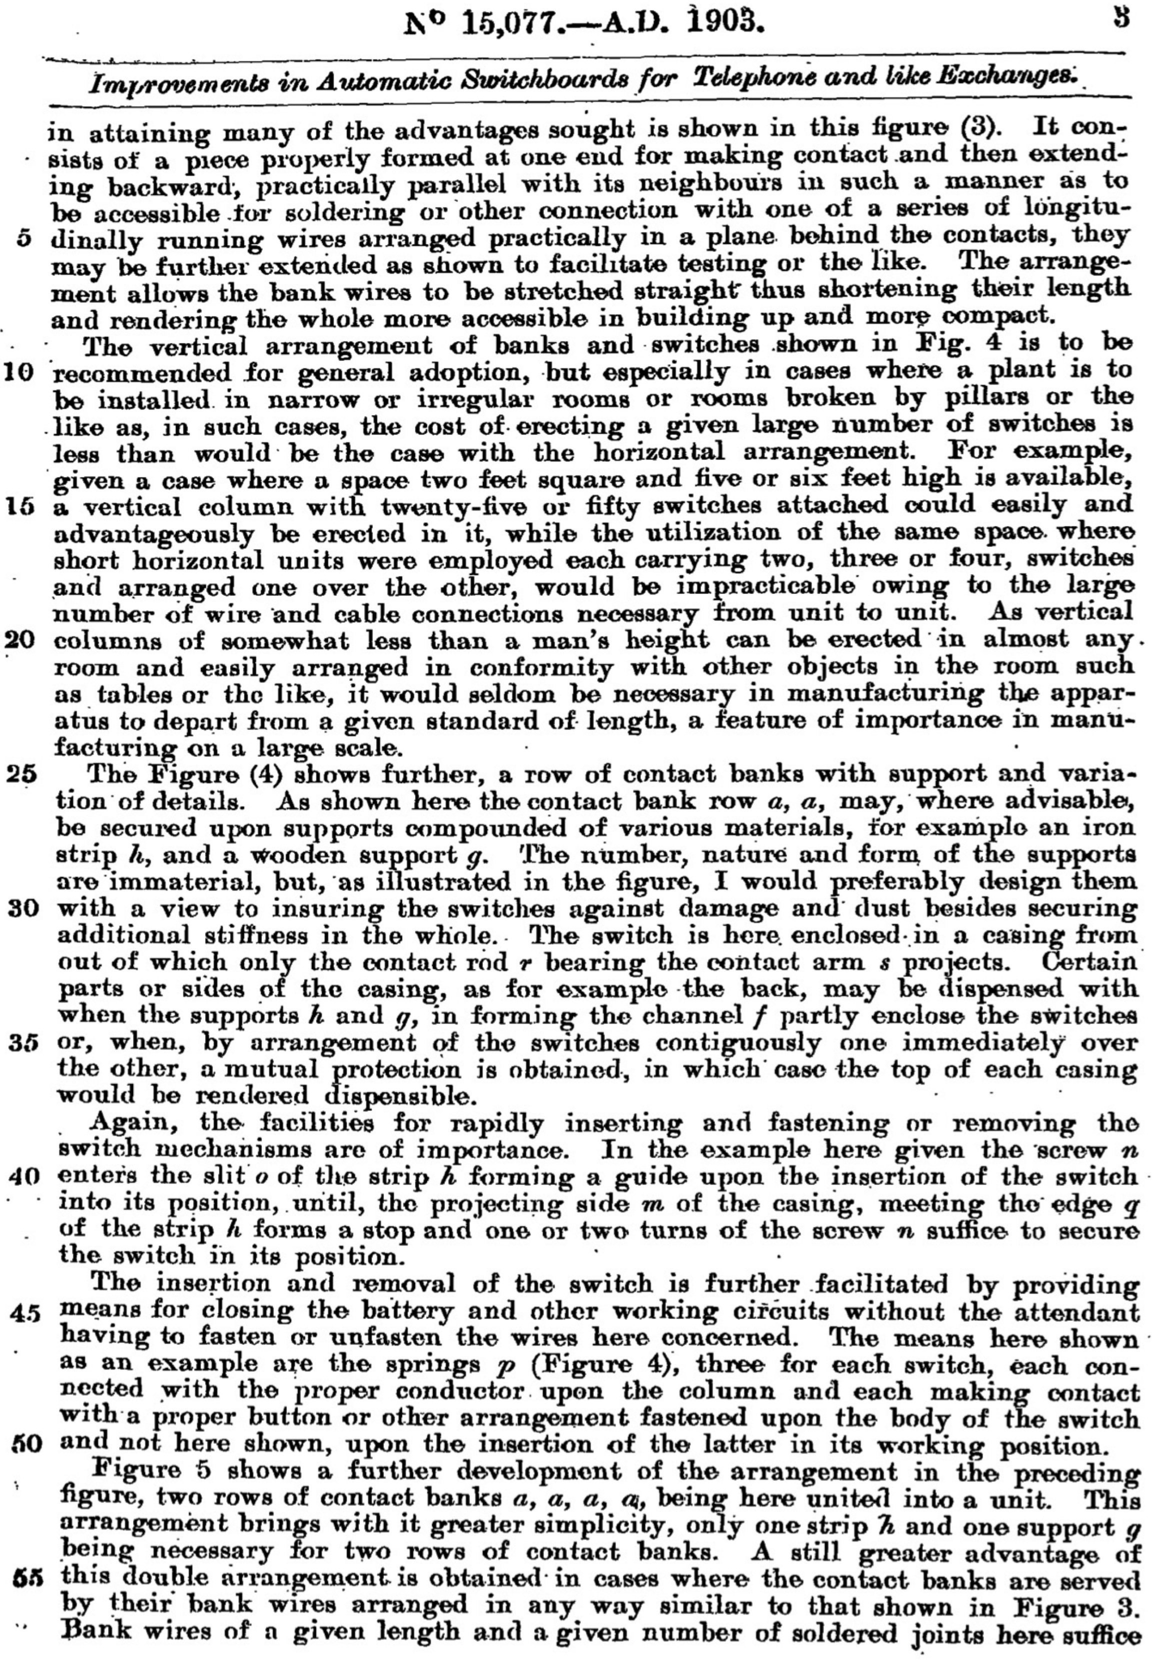
In the arrangement here shown (Figure 1) a further advantage is obtained by the abolishment of the cumbersome metal framing for each contact bank so often employed in systems now in use. The radially arranged contact pieces which, extending outward on either side of the contact field like spreading fingers, make a wide spacing between the fields necessary are also abolished. Both the framing and the radial contacts are shown in English Patent No. 22,545, 1898, Figs. 1 & 6 and 4 & 8. Further, the switches are arranged along beside the row not wholly or partly between the single banks as is the case in some systems. Under this arrangement the single contact fields as well as the switches can be brought close together and thus a very considerable economy of space and shortening of the bank wires *j*, *j*, is attained.

Figure 2 shows the same row arrangement as before with the difference that the contact banks, instead of being single, are manufactured in one continuous whole. The angle iron *b* of Figure 1 may here be dispensed with as the row is of such material and so constructed as to possess in itself the rigidity required.

Figure 3 illustrates a form similar to the last but with a different arrangement of the bank wires *j*, *j*. The figure gives an example of how it is possible to construct a row of contact banks alone or with the addition of the bank wires *j*, *j*, in one more or less rigid piece. By the insertion of stiff card-board or insulated metal between the layers of cable proper a high degree of stiffness can here be attained.

One form of contact piece employed by me, one which is very instrumental

Figure B.95: Albert Hanson filed detailed patent applications on printed circuits and multi-pin connectors in 1902–1903.



N° 15,077.—A.D. 1903. 3

Improvements in Automatic Switchboards for Telephone and like Exchanges.

in attaining many of the advantages sought is shown in this figure (3). It consists of a piece properly formed at one end for making contact and then extending backward, practically parallel with its neighbours in such a manner as to be accessible for soldering or other connection with one of a series of longitudinally running wires arranged practically in a plane behind the contacts, they may be further extended as shown to facilitate testing or the like. The arrangement allows the bank wires to be stretched straight thus shortening their length and rendering the whole more accessible in building up and more compact.

The vertical arrangement of banks and switches shown in Fig. 4 is to be recommended for general adoption, but especially in cases where a plant is to be installed in narrow or irregular rooms or rooms broken by pillars or the like as, in such cases, the cost of erecting a given large number of switches is less than would be the case with the horizontal arrangement. For example, given a case where a space two feet square and five or six feet high is available, a vertical column with twenty-five or fifty switches attached could easily and advantageously be erected in it, while the utilization of the same space where short horizontal units were employed each carrying two, three or four, switches and arranged one over the other, would be impracticable owing to the large number of wire and cable connections necessary from unit to unit. As vertical columns of somewhat less than a man's height can be erected in almost any room and easily arranged in conformity with other objects in the room such as tables or the like, it would seldom be necessary in manufacturing the apparatus to depart from a given standard of length, a feature of importance in manufacturing on a large scale.

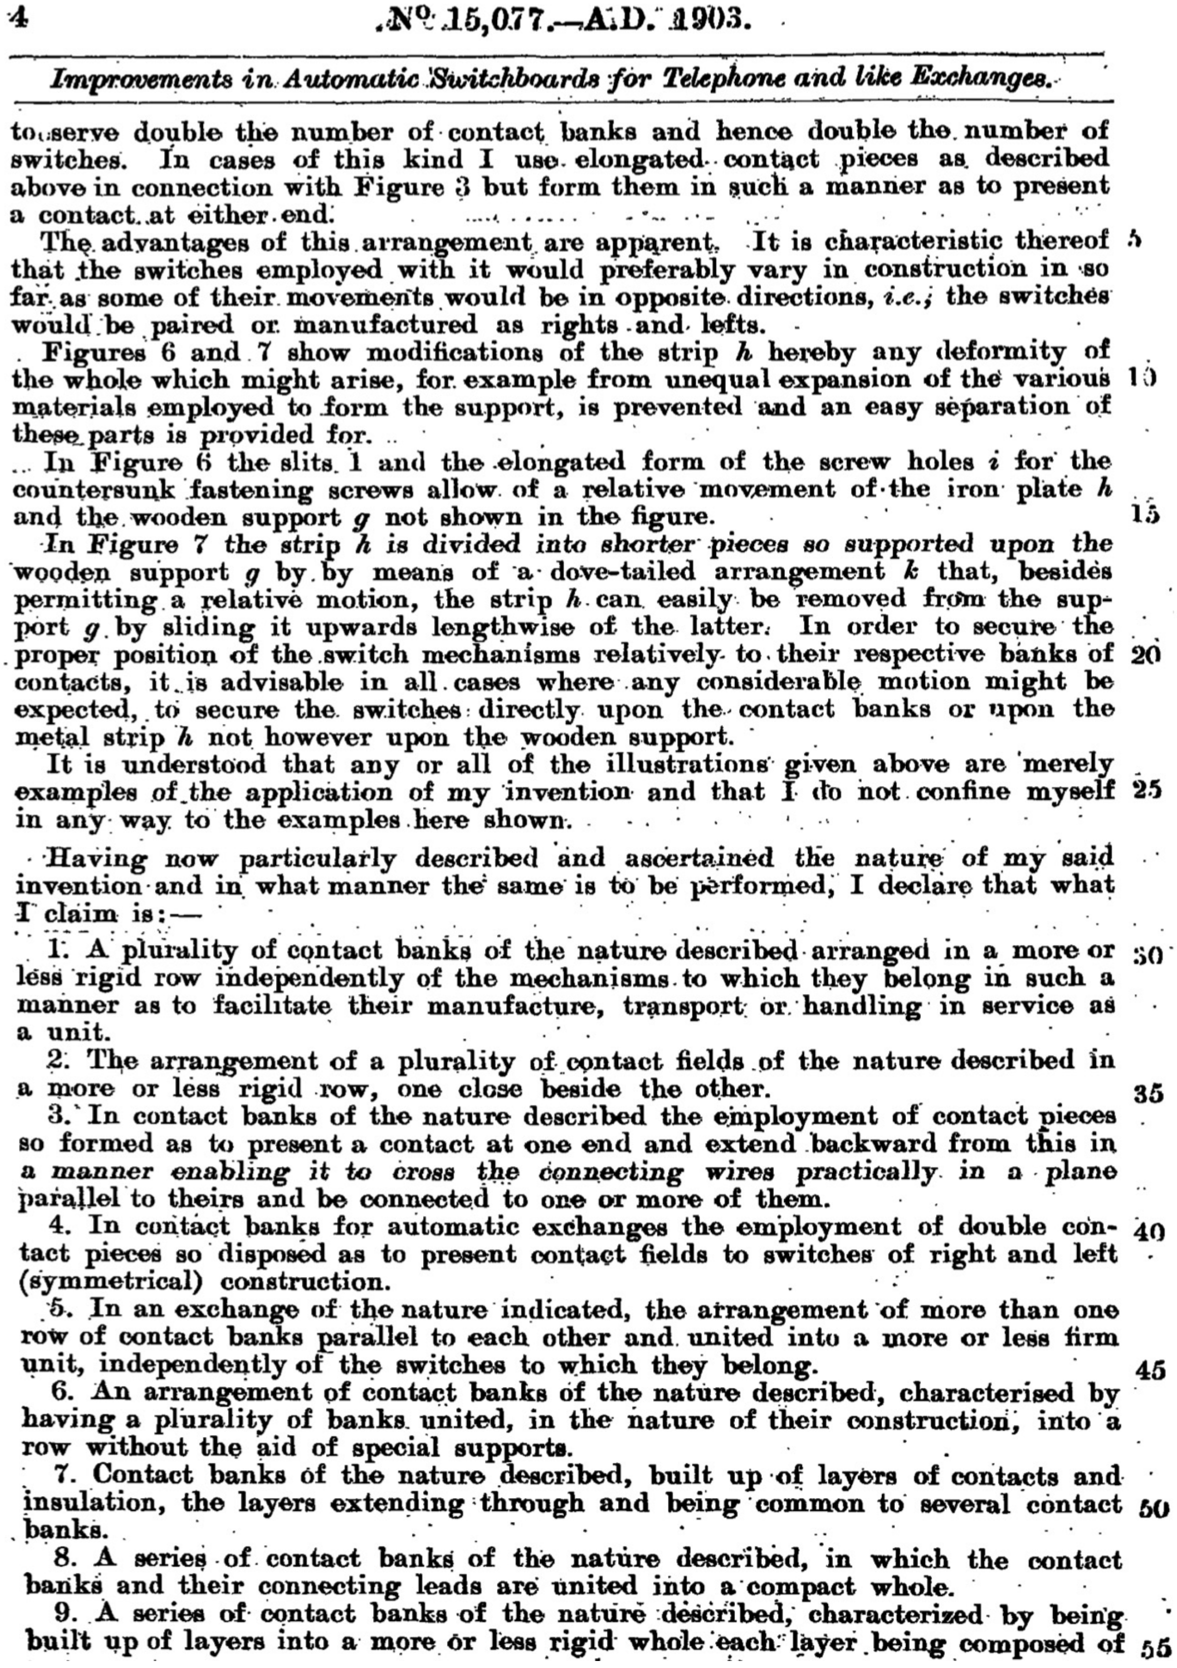
The Figure (4) shows further, a row of contact banks with support and variation of details. As shown here the contact bank row *a*, *a*, may, where advisable, be secured upon supports compounded of various materials, for example an iron strip *h*, and a wooden support *g*. The number, nature and form of the supports are immaterial, but, as illustrated in the figure, I would preferably design them with a view to insuring the switches against damage and dust besides securing additional stiffness in the whole. The switch is here enclosed in a casing from out of which only the contact rod *r* bearing the contact arm *s* projects. Certain parts or sides of the casing, as for example the back, may be dispensed with when the supports *h* and *g*, in forming the channel *f* partly enclose the switches or, when, by arrangement of the switches contiguously one immediately over the other, a mutual protection is obtained, in which case the top of each casing would be rendered dispensible.

Again, the facilities for rapidly inserting and fastening or removing the switch mechanisms are of importance. In the example here given the screw *n* enters the slit *o* of the strip *h* forming a guide upon the insertion of the switch into its position, until, the projecting side *m* of the casing, meeting the edge *q* of the strip *h* forms a stop and one or two turns of the screw *n* suffice to secure the switch in its position.

The insertion and removal of the switch is further facilitated by providing means for closing the battery and other working circuits without the attendant having to fasten or unfasten the wires here concerned. The means here shown as an example are the springs *p* (Figure 4), three for each switch, each connected with the proper conductor upon the column and each making contact with a proper button or other arrangement fastened upon the body of the switch and not here shown, upon the insertion of the latter in its working position.

Figure 5 shows a further development of the arrangement in the preceding figure, two rows of contact banks *a*, *a*, *a*, *a*, being here united into a unit. This arrangement brings with it greater simplicity, only one strip *h* and one support *g* being necessary for two rows of contact banks. A still greater advantage of this double arrangement is obtained in cases where the contact banks are served by their bank wires arranged in any way similar to that shown in Figure 3. Bank wires of a given length and a given number of soldered joints here suffice

Figure B.96: Albert Hanson filed detailed patent applications on printed circuits and multi-pin connectors in 1902–1903.



4 No. 15,077.—A.D. 1903.

Improvements in Automatic Switchboards for Telephone and like Exchanges.

to serve double the number of contact banks and hence double the number of switches. In cases of this kind I use elongated contact pieces as described above in connection with Figure 3 but form them in such a manner as to present a contact at either end.

The advantages of this arrangement are apparent. It is characteristic thereof that the switches employed with it would preferably vary in construction in so far as some of their movements would be in opposite directions, *i.e.*; the switches would be paired or manufactured as rights and lefts.

Figures 6 and 7 show modifications of the strip *h* hereby any deformity of the whole which might arise, for example from unequal expansion of the various materials employed to form the support, is prevented and an easy separation of these parts is provided for.

In Figure 6 the slits 1 and the elongated form of the screw holes *i* for the countersunk fastening screws allow of a relative movement of the iron plate *h* and the wooden support *g* not shown in the figure.

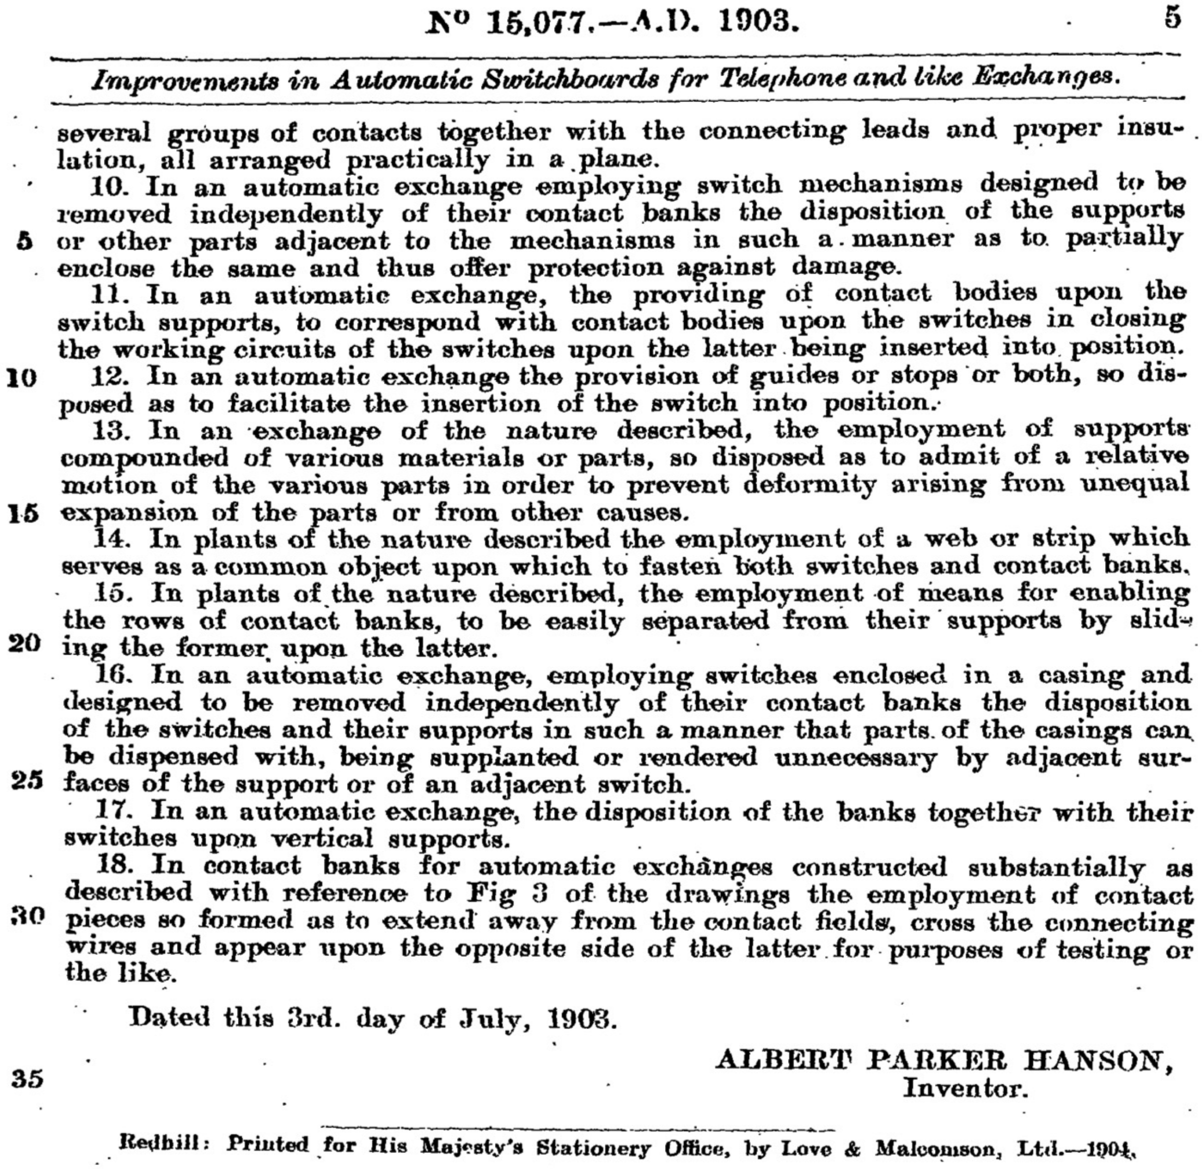
In Figure 7 the strip h is divided into shorter pieces so supported upon the wooden support *g* by by means of a dove-tailed arrangement *k* that, besides permitting a relative motion, the strip *h* can easily be removed from the support *g* by sliding it upwards lengthwise of the latter. In order to secure the proper position of the switch mechanisms relatively to their respective banks of contacts, it is advisable in all cases where any considerable motion might be expected, to secure the switches directly upon the contact banks or upon the metal strip *h* not however upon the wooden support.

It is understood that any or all of the illustrations given above are merely examples of the application of my invention and that I do not confine myself in any way to the examples here shown.

Having now particularly described and ascertained the nature of my said invention and in what manner the same is to be performed, I declare that what I claim is:—

1. A plurality of contact banks of the nature described arranged in a more or less rigid row independently of the mechanisms to which they belong in such a manner as to facilitate their manufacture, transport or handling in service as a unit.
2. The arrangement of a plurality of contact fields of the nature described in a more or less rigid row, one close beside the other.
3. In contact banks of the nature described the employment of contact pieces so formed as to present a contact at one end and extend backward from this in *a manner enabling it to cross the connecting wires practically* in a plane parallel to theirs and be connected to one or more of them.
4. In contact banks for automatic exchanges the employment of double contact pieces so disposed as to present contact fields to switches of right and left (symmetrical) construction.
5. In an exchange of the nature indicated, the arrangement of more than one row of contact banks parallel to each other and united into a more or less firm unit, independently of the switches to which they belong.
6. An arrangement of contact banks of the nature described, characterised by having a plurality of banks united, in the nature of their construction, into a row without the aid of special supports.
7. Contact banks of the nature described, built up of layers of contacts and insulation, the layers extending through and being common to several contact banks.
8. A series of contact banks of the nature described, in which the contact banks and their connecting leads are united into a compact whole.
9. A series of contact banks of the nature described, characterized by being built up of layers into a more or less rigid whole each layer being composed of

Figure B.97: Albert Hanson filed detailed patent applications on printed circuits and multi-pin connectors in 1902–1903.



Improvements in Automatic Switchboards for Telephone and like Exchanges.

several groups of contacts together with the connecting leads and proper insulation, all arranged practically in a plane.

10. In an automatic exchange employing switch mechanisms designed to be removed independently of their contact banks the disposition of the supports or other parts adjacent to the mechanisms in such a manner as to partially enclose the same and thus offer protection against damage.

11. In an automatic exchange, the providing of contact bodies upon the switch supports, to correspond with contact bodies upon the switches in closing the working circuits of the switches upon the latter being inserted into position.

12. In an automatic exchange the provision of guides or stops or both, so disposed as to facilitate the insertion of the switch into position.

13. In an exchange of the nature described, the employment of supports compounded of various materials or parts, so disposed as to admit of a relative motion of the various parts in order to prevent deformity arising from unequal expansion of the parts or from other causes.

14. In plants of the nature described the employment of a web or strip which serves as a common object upon which to fasten both switches and contact banks.

15. In plants of the nature described, the employment of means for enabling the rows of contact banks, to be easily separated from their supports by sliding the former upon the latter.

16. In an automatic exchange, employing switches enclosed in a casing and designed to be removed independently of their contact banks the disposition of the switches and their supports in such a manner that parts of the casings can be dispensed with, being supplanted or rendered unnecessary by adjacent surfaces of the support or of an adjacent switch.

17. In an automatic exchange, the disposition of the banks together with their switches upon vertical supports.

18. In contact banks for automatic exchanges constructed substantially as described with reference to Fig 3 of the drawings the employment of contact pieces so formed as to extend away from the contact fields, cross the connecting wires and appear upon the opposite side of the latter for purposes of testing or the like.

Dated this 3rd. day of July, 1903.

ALBERT PARKER HANSON,
Inventor.

Nº 4681 **A.D. 1903**

Date of Application, 27th Feb., 1903

Complete Specification Left, 28th Dec., 1903—Accepted, 27th May, 1904

PROVISIONAL SPECIFICATION.

Improvements in or connected with Electric Cables and the Jointing of the same.

I, Albert Parker Hanson, of 43 Dorotheenstrasse, Berlin, in the Kingdom of Prussia, Engineer, do hereby declare the nature of this invention to be as follows:—

My invention relates to improvements in or connected with electric cables and the jointing of the same, by means of which certain advantages are obtained; and it is specially though not exclusively applicable for telephone exchange purposes where it is desirable to have a large number of conductors led to the switch boards or switching devices within very small compass and yet with each conductor or group of conductors readily accessible for jointing, replacing or other purposes.

A cable constructed under my invention may be broadly stated to be one in which a number of conductors are arranged between layers of paper or other suitable material the said material being when desired perforated or arranged so as to leave gaps or openings for jointing or other desired purposes.

In order that the nature of my invention may be more readily understood I shall proceed to briefly refer to certain contemplated forms thereof which will I anticipate give good results in practice. In all the forms hereinafter mentioned the conductors may be bare or insulated in any convenient manner and they may be arranged singly or in pairs for working on metallic circuit and they may be crossed at intervals for the purpose of avoiding induction sounds.

In one contemplated form, the conductors are spaced apart and glued or cemented to sheets of paper and these are built up so that the cable consists of alternate layers of separated wires and of paper paraffined or otherwise treated when desired. Instead of paper, fabric or tissue of any desired material may be employed.

In another contemplated form instead of separating the conductors by flat strips or sheets of paper or other material they may be separated by a single sheet or strip which is folded or corrugated longitudinally. The wires are then placed at the bottoms of the folds or corrugations and the upper parts of the said material are then bent over laterally so that each conductor lies in a kind of elongated pocket and is completely separated from its neighbours.

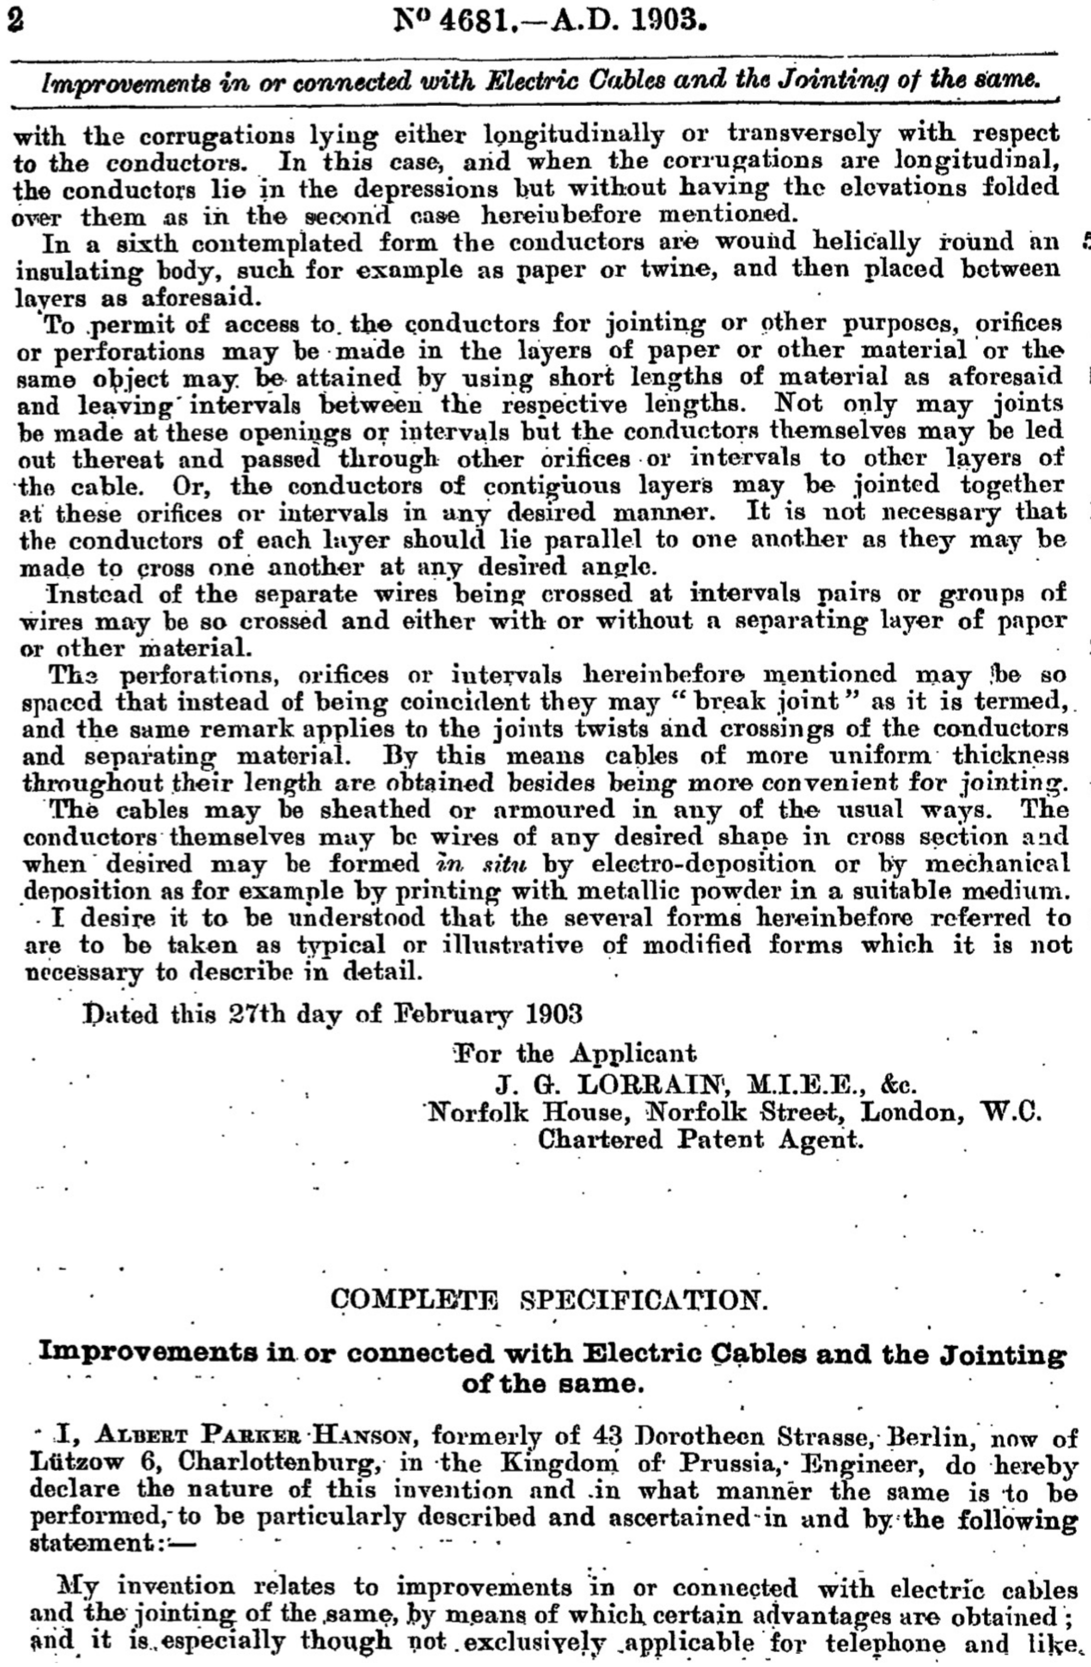
In a third form the conductors may simply rest between two layers of insulating material without being either cemented to or folded into the said material.

In a fourth contemplated form instead of separating the conductors by continuous lengths of paper or other material I use a number of short strips or layers of the latter spaced some distance apart so as to leave the conductors visible and accessible at intervals.

In a fifth contemplated form instead of using flat strips or layers, whether long or short, I employ corrugated strips or sheets, either long or short, and

[*Price* 8*d*.]

Figure B.100: Albert Hanson filed detailed patent applications on printed circuits and multi-pin connectors in 1902–1903.



2 No 4681.—A.D. 1903.

Improvements in or connected with Electric Cables and the Jointing of the same.

with the corrugations lying either longitudinally or transversely with respect to the conductors. In this case, and when the corrugations are longitudinal, the conductors lie in the depressions but without having the elevations folded over them as in the second case hereinbefore mentioned.

In a sixth contemplated form the conductors are wound helically round an insulating body, such for example as paper or twine, and then placed between layers as aforesaid.

To permit of access to the conductors for jointing or other purposes, orifices or perforations may be made in the layers of paper or other material or the same object may be attained by using short lengths of material as aforesaid and leaving intervals between the respective lengths. Not only may joints be made at these openings or intervals but the conductors themselves may be led out thereat and passed through other orifices or intervals to other layers of the cable. Or, the conductors of contiguous layers may be jointed together at these orifices or intervals in any desired manner. It is not necessary that the conductors of each layer should lie parallel to one another as they may be made to cross one another at any desired angle.

Instead of the separate wires being crossed at intervals pairs or groups of wires may be so crossed and either with or without a separating layer of paper or other material.

The perforations, orifices or intervals hereinbefore mentioned may be so spaced that instead of being coincident they may "break joint" as it is termed, and the same remark applies to the joints twists and crossings of the conductors and separating material. By this means cables of more uniform thickness throughout their length are obtained besides being more convenient for jointing.

The cables may be sheathed or armoured in any of the usual ways. The conductors themselves may be wires of any desired shape in cross section and when desired may be formed *in situ* by electro-deposition or by mechanical deposition as for example by printing with metallic powder in a suitable medium.

I desire it to be understood that the several forms hereinbefore referred to are to be taken as typical or illustrative of modified forms which it is not necessary to describe in detail.

Dated this 27th day of February 1903

For the Applicant
J. G. LORRAIN, M.I.E.E., &c.
Norfolk House, Norfolk Street, London, W.C.
Chartered Patent Agent.

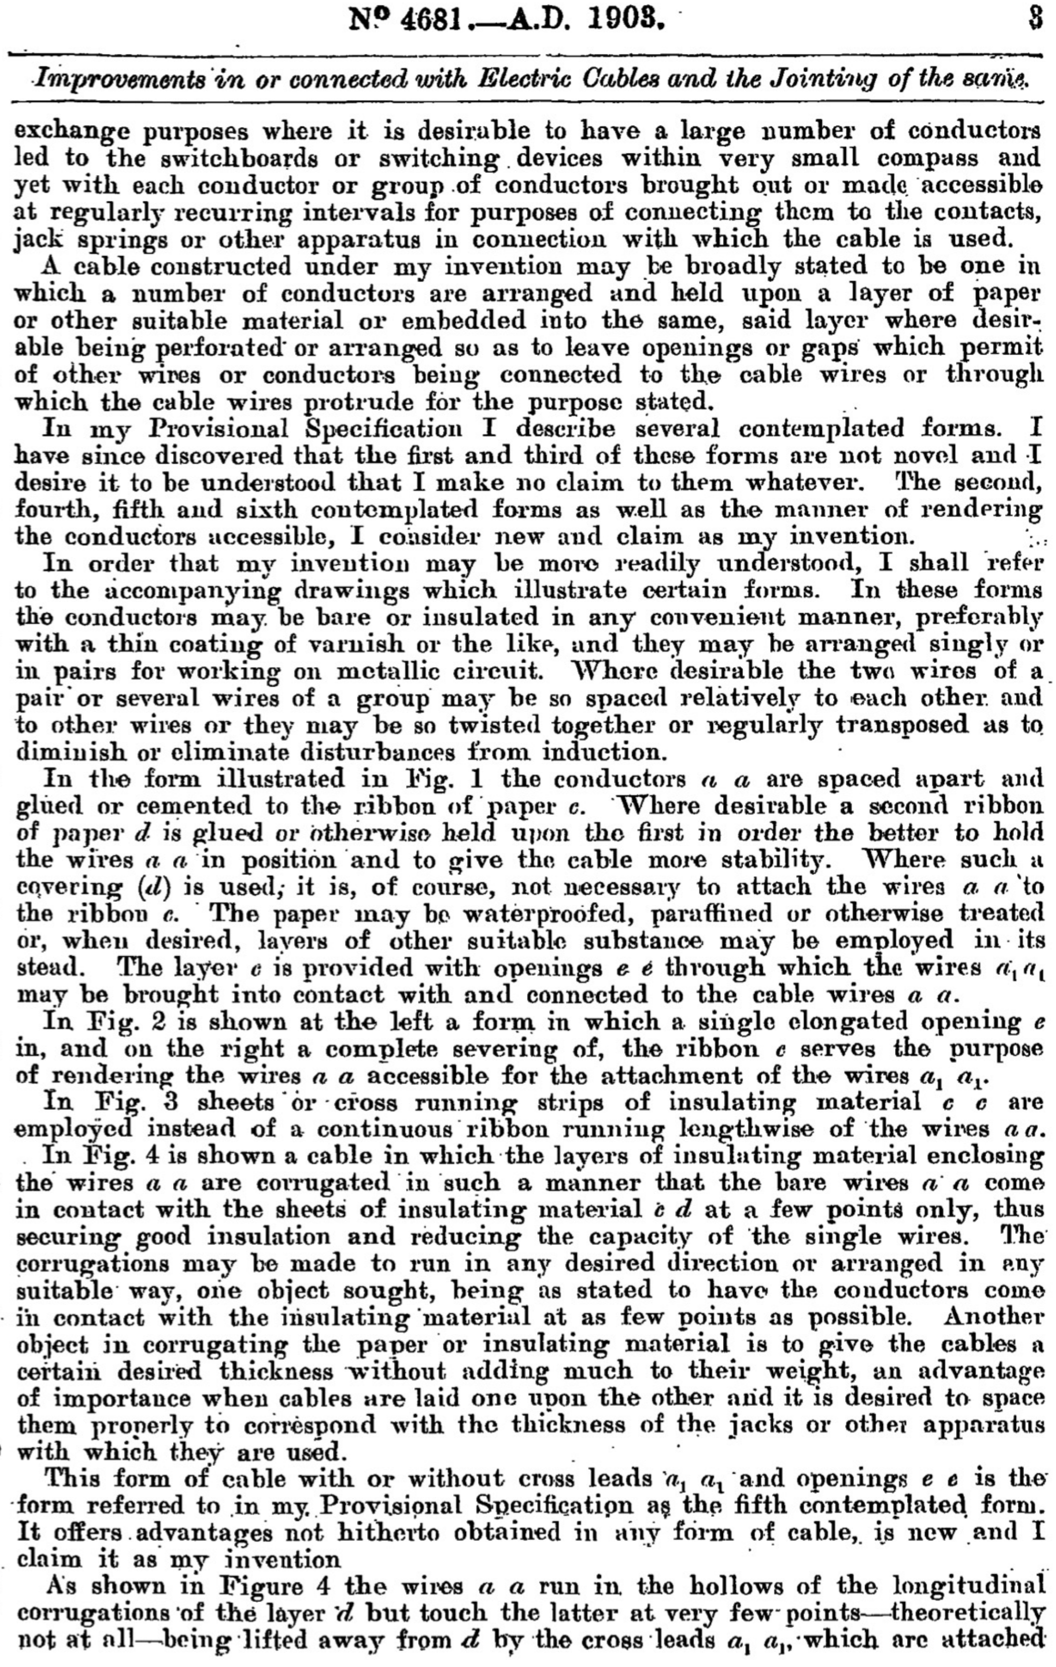
COMPLETE SPECIFICATION.

Improvements in or connected with Electric Cables and the Jointing of the same.

I, Albert Parker Hanson, formerly of 43 Dorotheen Strasse, Berlin, now of Lützow 6, Charlottenburg, in the Kingdom of Prussia, Engineer, do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:—

My invention relates to improvements in or connected with electric cables and the jointing of the same, by means of which certain advantages are obtained; and it is especially though not exclusively applicable for telephone and like

Figure B.101: Albert Hanson filed detailed patent applications on printed circuits and multi-pin connectors in 1902–1903.



Nº 4681.—A.D. 1903. 3

Improvements in or connected with Electric Cables and the Jointing of the same.

exchange purposes where it is desirable to have a large number of conductors led to the switchboards or switching devices within very small compass and yet with each conductor or group of conductors brought out or made accessible at regularly recurring intervals for purposes of connecting them to the contacts, jack springs or other apparatus in connection with which the cable is used.

A cable constructed under my invention may be broadly stated to be one in which a number of conductors are arranged and held upon a layer of paper or other suitable material or embedded into the same, said layer where desirable being perforated or arranged so as to leave openings or gaps which permit of other wires or conductors being connected to the cable wires or through which the cable wires protrude for the purpose stated.

In my Provisional Specification I describe several contemplated forms. I have since discovered that the first and third of these forms are not novel and I desire it to be understood that I make no claim to them whatever. The second, fourth, fifth and sixth contemplated forms as well as the manner of rendering the conductors accessible, I consider new and claim as my invention.

In order that my invention may be more readily understood, I shall refer to the accompanying drawings which illustrate certain forms. In these forms the conductors may be bare or insulated in any convenient manner, preferably with a thin coating of varnish or the like, and they may be arranged singly or in pairs for working on metallic circuit. Where desirable the two wires of a pair or several wires of a group may be so spaced relatively to each other and to other wires or they may be so twisted together or regularly transposed as to diminish or eliminate disturbances from induction.

In the form illustrated in Fig. 1 the conductors a a are spaced apart and glued or cemented to the ribbon of paper c. Where desirable a second ribbon of paper d is glued or otherwise held upon the first in order the better to hold the wires a a in position and to give the cable more stability. Where such a covering (d) is used, it is, of course, not necessary to attach the wires a a to the ribbon c. The paper may be waterproofed, paraffined or otherwise treated or, when desired, layers of other suitable substance may be employed in its stead. The layer c is provided with openings e e through which the wires a_1 a_1 may be brought into contact with and connected to the cable wires a a.

In Fig. 2 is shown at the left a form in which a single elongated opening e in, and on the right a complete severing of, the ribbon c serves the purpose of rendering the wires a a accessible for the attachment of the wires a_1 a_1.

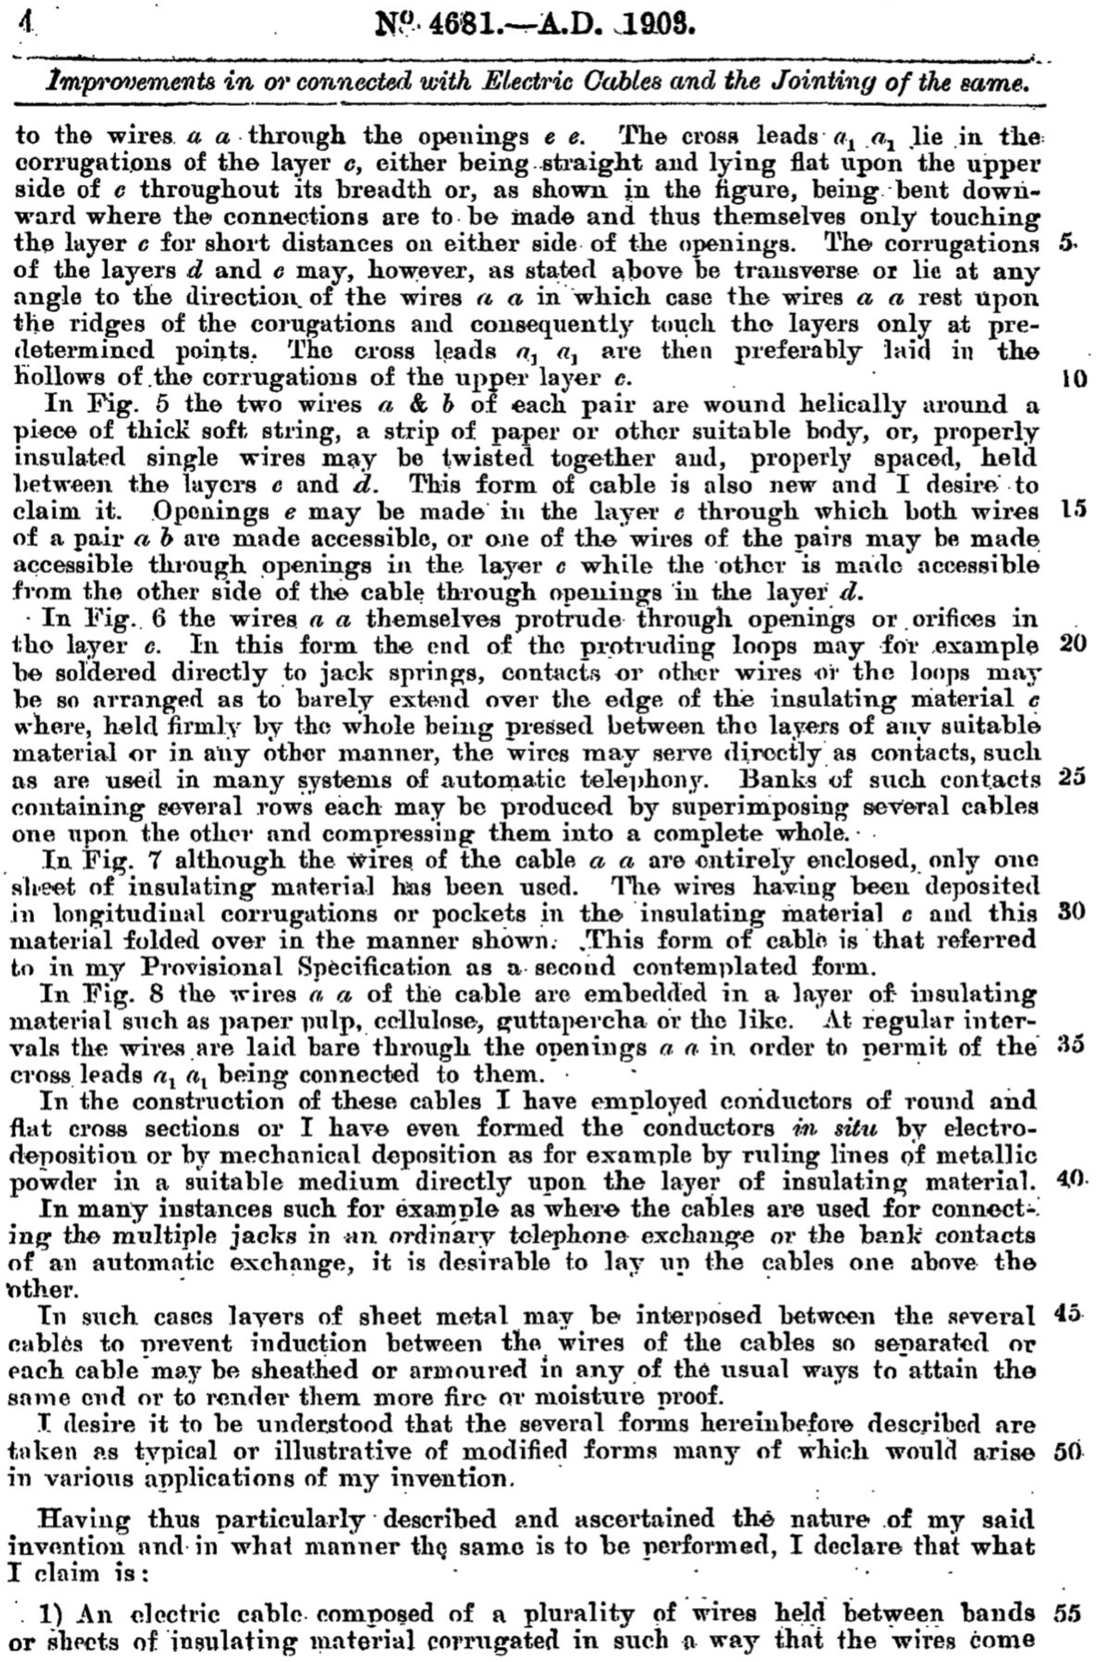
In Fig. 3 sheets or cross running strips of insulating material c c are employed instead of a continuous ribbon running lengthwise of the wires a a.

In Fig. 4 is shown a cable in which the layers of insulating material enclosing the wires a a are corrugated in such a manner that the bare wires a a come in contact with the sheets of insulating material c d at a few points only, thus securing good insulation and reducing the capacity of the single wires. The corrugations may be made to run in any desired direction or arranged in any suitable way, one object sought, being as stated to have the conductors come in contact with the insulating material at as few points as possible. Another object in corrugating the paper or insulating material is to give the cables a certain desired thickness without adding much to their weight, an advantage of importance when cables are laid one upon the other and it is desired to space them properly to correspond with the thickness of the jacks or other apparatus with which they are used.

This form of cable with or without cross leads a_1 a_1 and openings e e is the form referred to in my Provisional Specification as the fifth contemplated form. It offers advantages not hitherto obtained in any form of cable, is new and I claim it as my invention

As shown in Figure 4 the wires a a run in the hollows of the longitudinal corrugations of the layer d but touch the latter at very few points—theoretically not at all—being lifted away from d by the cross leads a_1 a_1, which are attached

Figure B.102: Albert Hanson filed detailed patent applications on printed circuits and multi-pin connectors in 1902–1903.



4 **Nº. 4681.—A.D. 1903.**

Improvements in or connected with Electric Cables and the Jointing of the same.

to the wires *a a* through the openings *e e*. The cross leads a_1 a_1 lie in the corrugations of the layer *c*, either being straight and lying flat upon the upper side of *c* throughout its breadth or, as shown in the figure, being bent downward where the connections are to be made and thus themselves only touching the layer *c* for short distances on either side of the openings. The corrugations of the layers *d* and *c* may, however, as stated above be transverse or lie at any angle to the direction of the wires *a a* in which case the wires *a a* rest upon the ridges of the corugations and consequently touch the layers only at predetermined points. The cross leads a_1 a_1 are then preferably laid in the hollows of the corrugations of the upper layer *c*.

In Fig. 5 the two wires *a* & *b* of each pair are wound helically around a piece of thick soft string, a strip of paper or other suitable body, or, properly insulated single wires may be twisted together and, properly spaced, held between the layers *c* and *d*. This form of cable is also new and I desire to claim it. Openings *e* may be made in the layer *c* through which both wires of a pair *a b* are made accessible, or one of the wires of the pairs may be made accessible through openings in the layer *c* while the other is made accessible from the other side of the cable through openings in the layer *d*.

In Fig. 6 the wires *a a* themselves protrude through openings or orifices in the layer *c*. In this form the end of the protruding loops may for example be soldered directly to jack springs, contacts or other wires or the loops may be so arranged as to barely extend over the edge of the insulating material *c* where, held firmly by the whole being pressed between the layers of any suitable material or in any other manner, the wires may serve directly as contacts, such as are used in many systems of automatic telephony. Banks of such contacts containing several rows each may be produced by superimposing several cables one upon the other and compressing them into a complete whole.

In Fig. 7 although the wires of the cable *a a* are entirely enclosed, only one sheet of insulating material has been used. The wires having been deposited in longitudinal corrugations or pockets in the insulating material *c* and this material folded over in the manner shown. This form of cable is that referred to in my Provisional Specification as a second contemplated form.

In Fig. 8 the wires *a a* of the cable are embedded in a layer of insulating material such as paper pulp, cellulose, guttapercha or the like. At regular intervals the wires are laid bare through the openings *a a* in order to permit of the cross leads a_1 a_1 being connected to them.

In the construction of these cables I have employed conductors of round and flat cross sections or I have even formed the conductors *in situ* by electrodeposition or by mechanical deposition as for example by ruling lines of metallic powder in a suitable medium directly upon the layer of insulating material.

In many instances such for example as where the cables are used for connecting the multiple jacks in an ordinary telephone exchange or the bank contacts of an automatic exchange, it is desirable to lay up the cables one above the other.

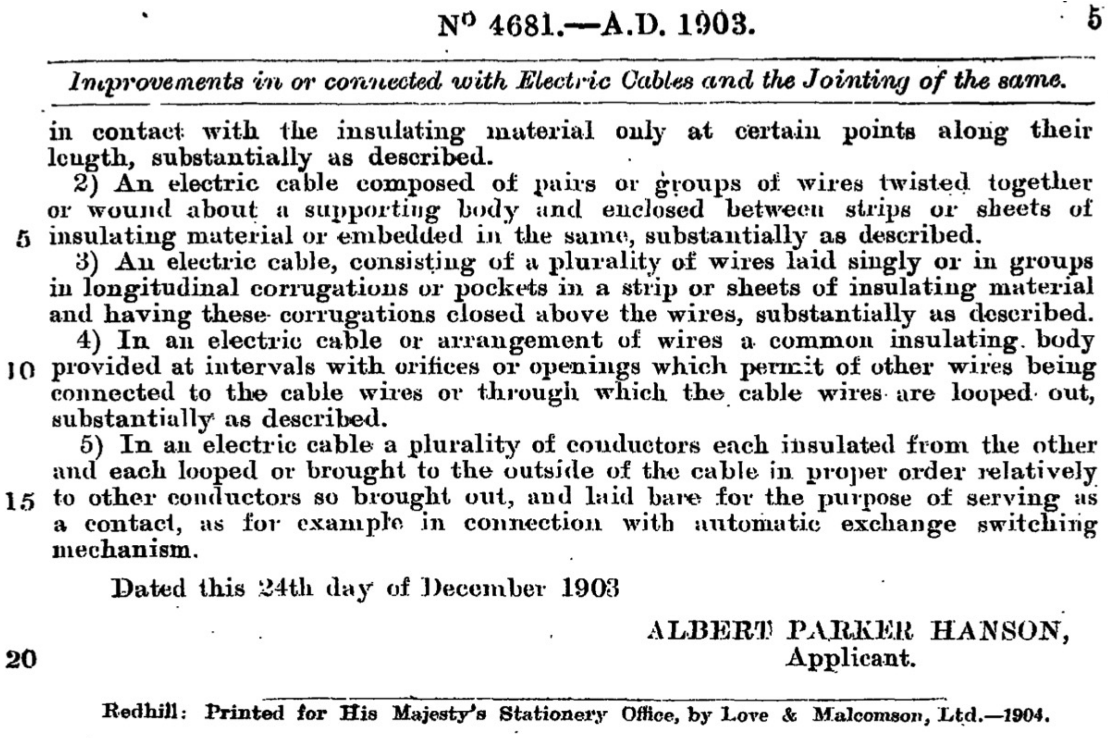
In such cases layers of sheet metal may be interposed between the several cables to prevent induction between the wires of the cables so separated or each cable may be sheathed or armoured in any of the usual ways to attain the same end or to render them more fire or moisture proof.

I desire it to be understood that the several forms hereinbefore described are taken as typical or illustrative of modified forms many of which would arise in various applications of my invention.

Having thus particularly described and ascertained the nature of my said invention and in what manner the same is to be performed, I declare that what I claim is:

1) An electric cable composed of a plurality of wires held between bands or sheets of insulating material corrugated in such a way that the wires come

Figure B.103: Albert Hanson filed detailed patent applications on printed circuits and multi-pin connectors in 1902–1903.



Nº 4681.—A.D. 1903. 5

Improvements in or connected with Electric Cables and the Jointing of the same.

in contact with the insulating material only at certain points along their length, substantially as described.

2) An electric cable composed of pairs or groups of wires twisted together or wound about a supporting body and enclosed between strips or sheets of insulating material or embedded in the same, substantially as described.

3) An electric cable, consisting of a plurality of wires laid singly or in groups in longitudinal corrugations or pockets in a strip or sheets of insulating material and having these corrugations closed above the wires, substantially as described.

4) In an electric cable or arrangement of wires a common insulating body provided at intervals with orifices or openings which permit of other wires being connected to the cable wires or through which the cable wires are looped out, substantially as described.

5) In an electric cable a plurality of conductors each insulated from the other and each looped or brought to the outside of the cable in proper order relatively to other conductors so brought out, and laid bare for the purpose of serving as a contact, as for example in connection with automatic exchange switching mechanism.

Dated this 24th day of December 1903

In Great Britain February 2, 1943

7 Claims. (Cl. 41—43)

1

This invention relates to the manufacture of electrical apparatus, and particularly to the production of electric and magnetic circuits and parts thereof.

A principal purpose of the invention is to facilitate and cheapen quantity production of electric circuit components, such as the resistances, inductances, transformers, tubes, and interconnecting networks or circuit connections of radio apparatus, the cores and windings of iron-cored transformers and dynamo electric machines, the connecting networks of switchboards, the conductors of heating appliances, and generally of any electrical circuit component which it may be convenient to manufacture by the methods herein disclosed.

A further purpose of the invention is to facilitate the production of electrical circuit components, even though they be not needed in great quantities, in which a high degree of precision is required in the dimensioning or relative location of conductors such as cannot readily be obtained by known means.

Yet another object of the invention is the production of surface heating elements in which the conductor also constitutes or carries an ornamentation.

Other objects of the invention will appear from the description following.

Most electrical circuit components essentially comprise metal parts, conducting electric current or magnetic flux, supported upon an insulating base, or with interposed insulation upon a metal base.

The invention consists in the production of the metal electric and magnetic conductors in position upon their insulating support by a process based on the printing of a representation of the conductive metal.

The common way of building up an electrical circuit or circuit element is first to draw metal into wire, that is to say make a linear conductor, and afterwards to shape this conductor into coils and networks. By the application of the methods of the printing art the invention brings the metal conductor of the circuit component into existence in its final form, or in a development of that form upon a plane or cylindrical surface.

A typical instance of the invention comprises the steps of preparing by any of the well-known methods of the printing art, a printing plate for printing a representation of the metal electric or magnetic conductors of the circuit component or a part of them; making an imprint

2

by the aid of the printing plate upon a surface thereby differentiating on that surface the areas which are required to be conductive from the areas which are required to be non-conductive; and from that imprint producing the conductor by subjecting the printed surface to treatment which operates differently on the areas of the surface differentiated by the printing, thereby changing the differentiation into a differentiation of conductive and non-conductive areas.

The development of the conductor from the imprint is in most cases effected by methods adapted from the printing art or analogous to the methods of the printing art, such as etching, bronzing, electro-deposition and the like.

Where on account of the process of development adopted, or on account of the nature of the fabric which is to form the permanent base of the conductor, it is inconvenient to make the imprint on the permanent base, it may be made on a temporary base, which must be removable, and the development process be followed by a transfer process akin to those known in the printing art.

The invention is explained hereinafter by a description of the production of various circuit components by its aid. This description refers to the accompanying drawings in which—

Figure 1 is a diagram of connections of a radio receiver.

Figure 2 is a diagram showing the approximate lay-out of the components of this receiver.

Figures 3 and 4 show two part schemes of connections prepared for the purpose of applying the invention to the manufacture of the circuit connections of this receiver.

Figure 5 is a cross-section illustrating the making of connections between one part scheme of connections and another and between the circuit leads and a component by means of an eyelet.

Figure 6 is a cross-section illustrating the making of connections between one part scheme of connections and another and between the circuit leads and a component by means of stitching wire.

Figure 7 is a pattern of flat spirals illustrating the making of inductance coils according to the invention by printing with the additional step of folding.

Figure 8 illustrates another way of joining parts of a component.

Figure 9 illustrates a printed pattern of parallel conductors having many useful applications.

Figure B.116: Paul Eisler produced printed circuits in 1936 and filed a detailed patent application in 1944.

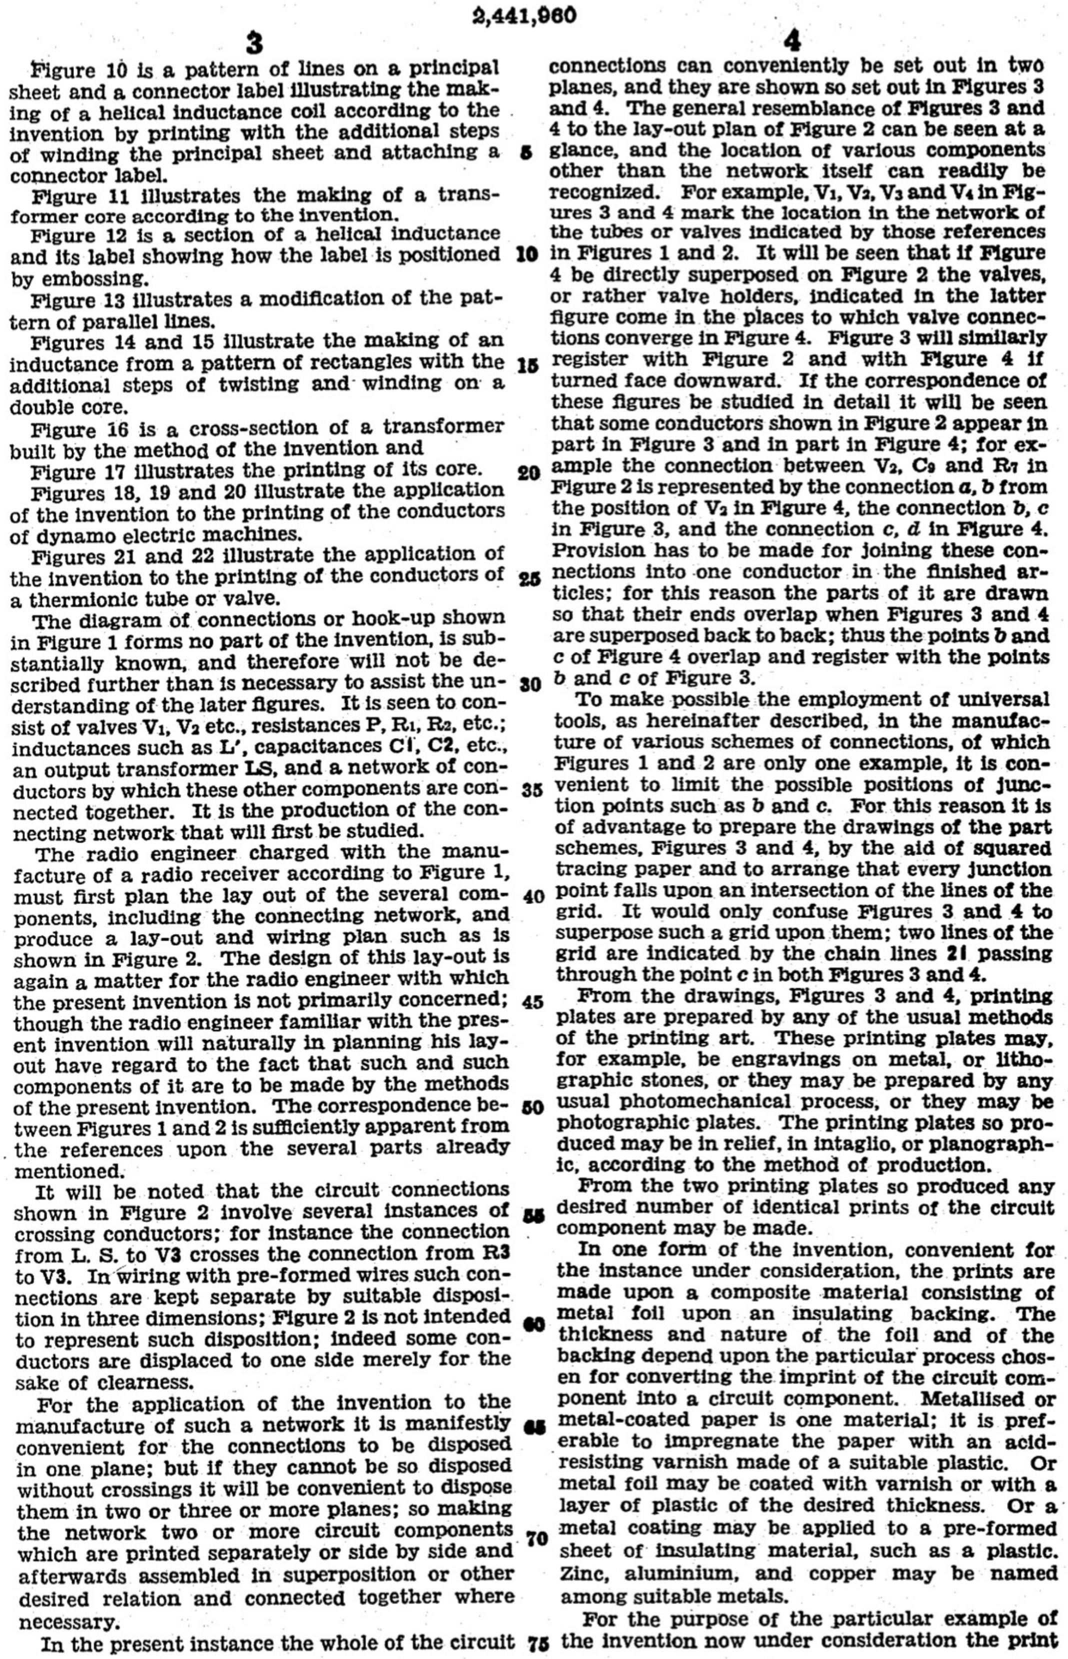

Figure 10 is a pattern of lines on a principal sheet and a connector label illustrating the making of a helical inductance coil according to the invention by printing with the additional steps of winding the principal sheet and attaching a connector label.

Figure 11 illustrates the making of a transformer core according to the invention.

Figure 12 is a section of a helical inductance and its label showing how the label is positioned by embossing.

Figure 13 illustrates a modification of the pattern of parallel lines.

Figures 14 and 15 illustrate the making of an inductance from a pattern of rectangles with the additional steps of twisting and winding on a double core.

Figure 16 is a cross-section of a transformer built by the method of the invention and

Figure 17 illustrates the printing of its core.

Figures 18, 19 and 20 illustrate the application of the invention to the printing of the conductors of dynamo electric machines.

Figures 21 and 22 illustrate the application of the invention to the printing of the conductors of a thermionic tube or valve.

The diagram of connections or hook-up shown in Figure 1 forms no part of the invention, is substantially known, and therefore will not be described further than is necessary to assist the understanding of the later figures. It is seen to consist of valves V_1, V_2 etc., resistances P, R_1, R_2, etc.; inductances such as L′, capacitances C1, C2, etc., an output transformer LS, and a network of conductors by which these other components are connected together. It is the production of the connecting network that will first be studied.

The radio engineer charged with the manufacture of a radio receiver according to Figure 1, must first plan the lay out of the several components, including the connecting network, and produce a lay-out and wiring plan such as is shown in Figure 2. The design of this lay-out is again a matter for the radio engineer with which the present invention is not primarily concerned; though the radio engineer familiar with the present invention will naturally in planning his layout have regard to the fact that such and such components of it are to be made by the methods of the present invention. The correspondence between Figures 1 and 2 is sufficiently apparent from the references upon the several parts already mentioned.

It will be noted that the circuit connections shown in Figure 2 involve several instances of crossing conductors; for instance the connection from L. S. to V3 crosses the connection from R3 to V3. In wiring with pre-formed wires such connections are kept separate by suitable disposition in three dimensions; Figure 2 is not intended to represent such disposition; indeed some conductors are displaced to one side merely for the sake of clearness.

For the application of the invention to the manufacture of such a network it is manifestly convenient for the connections to be disposed in one plane; but if they cannot be so disposed without crossings it will be convenient to dispose them in two or three or more planes; so making the network two or more circuit components which are printed separately or side by side and afterwards assembled in superposition or other desired relation and connected together where necessary.

In the present instance the whole of the circuit connections can conveniently be set out in two planes, and they are shown so set out in Figures 3 and 4. The general resemblance of Figures 3 and 4 to the lay-out plan of Figure 2 can be seen at a glance, and the location of various components other than the network itself can readily be recognized. For example, V_1, V_2, V_3 and V_4 in Figures 3 and 4 mark the location in the network of the tubes or valves indicated by those references in Figures 1 and 2. It will be seen that if Figure 4 be directly superposed on Figure 2 the valves, or rather valve holders, indicated in the latter figure come in the places to which valve connections converge in Figure 4. Figure 3 will similarly register with Figure 2 and with Figure 4 if turned face downward. If the correspondence of these figures be studied in detail it will be seen that some conductors shown in Figure 2 appear in part in Figure 3 and in part in Figure 4; for example the connection between V_2, C_9 and R_7 in Figure 2 is represented by the connection *a*, *b* from the position of V_2 in Figure 4, the connection *b*, *c* in Figure 3, and the connection *c*, *d* in Figure 4. Provision has to be made for joining these connections into one conductor in the finished articles; for this reason the parts of it are drawn so that their ends overlap when Figures 3 and 4 are superposed back to back; thus the points *b* and *c* of Figure 4 overlap and register with the points *b* and *c* of Figure 3.

To make possible the employment of universal tools, as hereinafter described, in the manufacture of various schemes of connections, of which Figures 1 and 2 are only one example, it is convenient to limit the possible positions of junction points such as *b* and *c*. For this reason it is of advantage to prepare the drawings of the part schemes, Figures 3 and 4, by the aid of squared tracing paper and to arrange that every junction point falls upon an intersection of the lines of the grid. It would only confuse Figures 3 and 4 to superpose such a grid upon them; two lines of the grid are indicated by the chain lines **21** passing through the point *c* in both Figures 3 and 4.

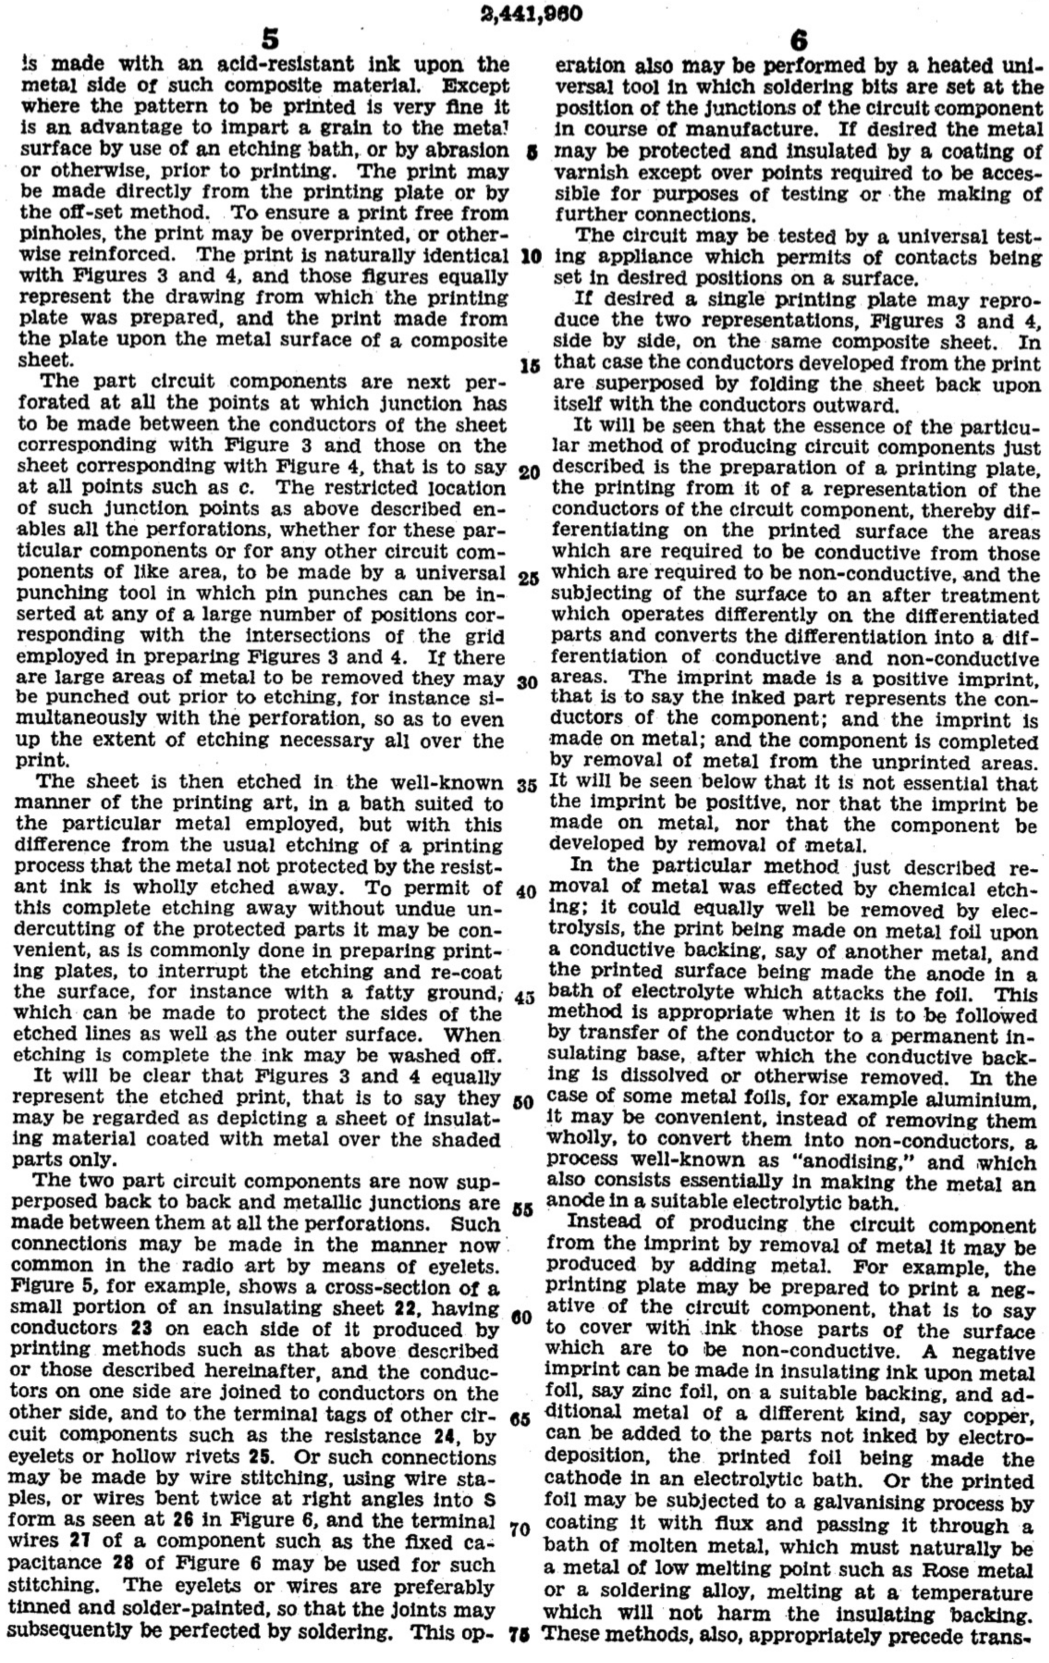
From the drawings, Figures 3 and 4, printing plates are prepared by any of the usual methods of the printing art. These printing plates may, for example, be engravings on metal, or lithographic stones, or they may be prepared by any usual photomechanical process, or they may be photographic plates. The printing plates so produced may be in relief, in intaglio, or planographic, according to the method of production.

From the two printing plates so produced any desired number of identical prints of the circuit component may be made.

In one form of the invention, convenient for the instance under consideration, the prints are made upon a composite material consisting of metal foil upon an insulating backing. The thickness and nature of the foil and of the backing depend upon the particular process chosen for converting the imprint of the circuit component into a circuit component. Metallised or metal-coated paper is one material; it is preferable to impregnate the paper with an acid-resisting varnish made of a suitable plastic. Or metal foil may be coated with varnish or with a layer of plastic of the desired thickness. Or a metal coating may be applied to a pre-formed sheet of insulating material, such as a plastic. Zinc, aluminium, and copper may be named among suitable metals.

For the purpose of the particular example of the invention now under consideration the print

Figure B.117: Paul Eisler produced printed circuits in 1936 and filed a detailed patent application in 1944.



2,441,960

5

is made with an acid-resistant ink upon the metal side of such composite material. Except where the pattern to be printed is very fine it is an advantage to impart a grain to the metal surface by use of an etching bath, or by abrasion or otherwise, prior to printing. The print may be made directly from the printing plate or by the off-set method. To ensure a print free from pinholes, the print may be overprinted, or otherwise reinforced. The print is naturally identical with Figures 3 and 4, and those figures equally represent the drawing from which the printing plate was prepared, and the print made from the plate upon the metal surface of a composite sheet.

The part circuit components are next perforated at all the points at which junction has to be made between the conductors of the sheet corresponding with Figure 3 and those on the sheet corresponding with Figure 4, that is to say at all points such as *c*. The restricted location of such junction points as above described enables all the perforations, whether for these particular components or for any other circuit components of like area, to be made by a universal punching tool in which pin punches can be inserted at any of a large number of positions corresponding with the intersections of the grid employed in preparing Figures 3 and 4. If there are large areas of metal to be removed they may be punched out prior to etching, for instance simultaneously with the perforation, so as to even up the extent of etching necessary all over the print.

The sheet is then etched in the well-known manner of the printing art, in a bath suited to the particular metal employed, but with this difference from the usual etching of a printing process that the metal not protected by the resistant ink is wholly etched away. To permit of this complete etching away without undue undercutting of the protected parts it may be convenient, as is commonly done in preparing printing plates, to interrupt the etching and re-coat the surface, for instance with a fatty ground, which can be made to protect the sides of the etched lines as well as the outer surface. When etching is complete the ink may be washed off.

It will be clear that Figures 3 and 4 equally represent the etched print, that is to say they may be regarded as depicting a sheet of insulating material coated with metal over the shaded parts only.

The two part circuit components are now superposed back to back and metallic junctions are made between them at all the perforations. Such connections may be made in the manner now common in the radio art by means of eyelets. Figure 5, for example, shows a cross-section of a small portion of an insulating sheet **22**, having conductors **23** on each side of it produced by printing methods such as that above described or those described hereinafter, and the conductors on one side are joined to conductors on the other side, and to the terminal tags of other circuit components such as the resistance **24**, by eyelets or hollow rivets **25**. Or such connections may be made by wire stitching, using wire staples, or wires bent twice at right angles into S form as seen at **26** in Figure 6, and the terminal wires **27** of a component such as the fixed capacitance **28** of Figure 6 may be used for such stitching. The eyelets or wires are preferably tinned and solder-painted, so that the joints may subsequently be perfected by soldering. This operation also may be performed by a heated universal tool in which soldering bits are set at the position of the junctions of the circuit component in course of manufacture. If desired the metal may be protected and insulated by a coating of varnish except over points required to be accessible for purposes of testing or the making of further connections.

6

The circuit may be tested by a universal testing appliance which permits of contacts being set in desired positions on a surface.

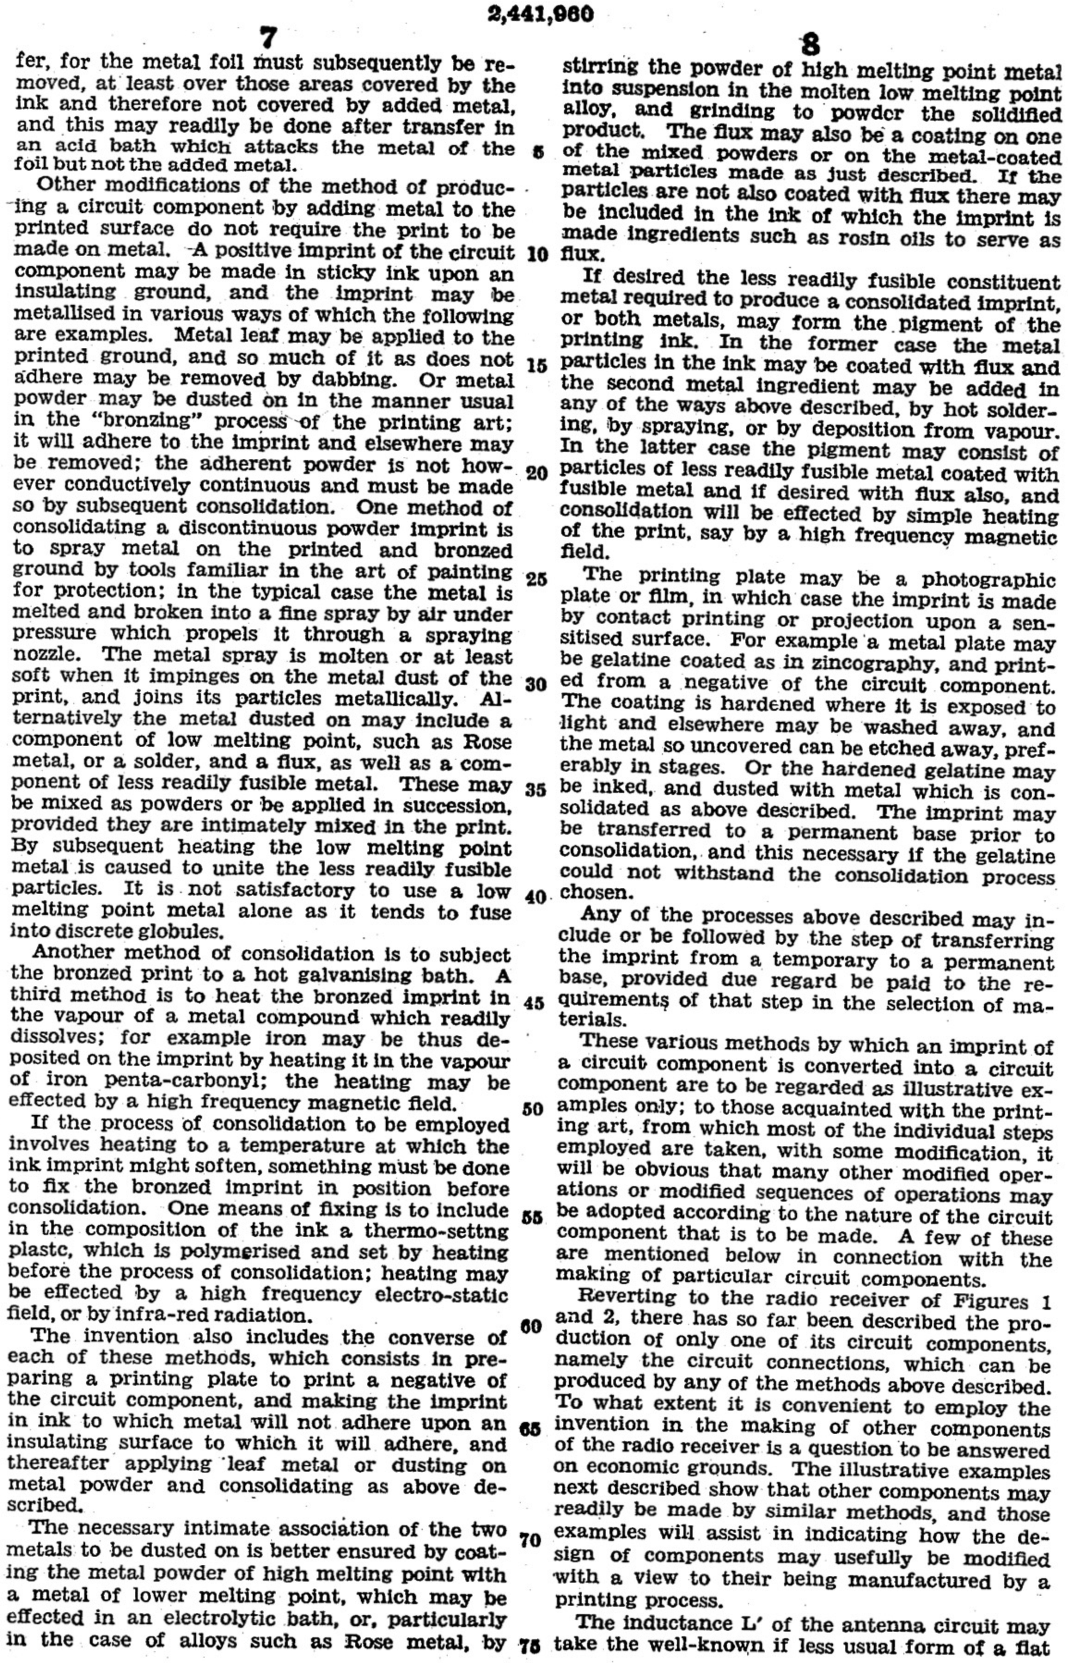
If desired a single printing plate may reproduce the two representations, Figures 3 and 4, side by side, on the same composite sheet. In that case the conductors developed from the print are superposed by folding the sheet back upon itself with the conductors outward.

It will be seen that the essence of the particular method of producing circuit components just described is the preparation of a printing plate, the printing from it of a representation of the conductors of the circuit component, thereby differentiating on the printed surface the areas which are required to be conductive from those which are required to be non-conductive, and the subjecting of the surface to an after treatment which operates differently on the differentiated parts and converts the differentiation into a differentiation of conductive and non-conductive areas. The imprint made is a positive imprint, that is to say the inked part represents the conductors of the component; and the imprint is made on metal; and the component is completed by removal of metal from the unprinted areas. It will be seen below that it is not essential that the imprint be positive, nor that the imprint be made on metal, nor that the component be developed by removal of metal.

In the particular method just described removal of metal was effected by chemical etching; it could equally well be removed by electrolysis, the print being made on metal foil upon a conductive backing, say of another metal, and the printed surface being made the anode in a bath of electrolyte which attacks the foil. This method is appropriate when it is to be followed by transfer of the conductor to a permanent insulating base, after which the conductive backing is dissolved or otherwise removed. In the case of some metal foils, for example aluminium, it may be convenient, instead of removing them wholly, to convert them into non-conductors, a process well-known as "anodising," and which also consists essentially in making the metal an anode in a suitable electrolytic bath.

Instead of producing the circuit component from the imprint by removal of metal it may be produced by adding metal. For example, the printing plate may be prepared to print a negative of the circuit component, that is to say to cover with ink those parts of the surface which are to be non-conductive. A negative imprint can be made in insulating ink upon metal foil, say zinc foil, on a suitable backing, and additional metal of a different kind, say copper, can be added to the parts not inked by electrodeposition, the printed foil being made the cathode in an electrolytic bath. Or the printed foil may be subjected to a galvanising process by coating it with flux and passing it through a bath of molten metal, which must naturally be a metal of low melting point such as Rose metal or a soldering alloy, melting at a temperature which will not harm the insulating backing. These methods, also, appropriately precede trans-

Figure B.118: Paul Eisler produced printed circuits in 1936 and filed a detailed patent application in 1944.



2,441,960

7

fer, for the metal foil must subsequently be removed, at least over those areas covered by the ink and therefore not covered by added metal, and this may readily be done after transfer in an acid bath which attacks the metal of the foil but not the added metal.

Other modifications of the method of producing a circuit component by adding metal to the printed surface do not require the print to be made on metal. A positive imprint of the circuit component may be made in sticky ink upon an insulating ground, and the imprint may be metallised in various ways of which the following are examples. Metal leaf may be applied to the printed ground, and so much of it as does not adhere may be removed by dabbing. Or metal powder may be dusted on in the manner usual in the "bronzing" process of the printing art; it will adhere to the imprint and elsewhere may be removed; the adherent powder is not however conductively continuous and must be made so by subsequent consolidation. One method of consolidating a discontinuous powder imprint is to spray metal on the printed and bronzed ground by tools familiar in the art of painting for protection; in the typical case the metal is melted and broken into a fine spray by air under pressure which propels it through a spraying nozzle. The metal spray is molten or at least soft when it impinges on the metal dust of the print, and joins its particles metallically. Alternatively the metal dusted on may include a component of low melting point, such as Rose metal, or a solder, and a flux, as well as a component of less readily fusible metal. These may be mixed as powders or be applied in succession, provided they are intimately mixed in the print. By subsequent heating the low melting point metal is caused to unite the less readily fusible particles. It is not satisfactory to use a low melting point metal alone as it tends to fuse into discrete globules.

Another method of consolidation is to subject the bronzed print to a hot galvanising bath. A third method is to heat the bronzed imprint in the vapour of a metal compound which readily dissolves; for example iron may be thus deposited on the imprint by heating it in the vapour of iron penta-carbonyl; the heating may be effected by a high frequency magnetic field.

If the process of consolidation to be employed involves heating to a temperature at which the ink imprint might soften, something must be done to fix the bronzed imprint in position before consolidation. One means of fixing is to include in the composition of the ink a thermo-settng plastc, which is polymerised and set by heating before the process of consolidation; heating may be effected by a high frequency electro-static field, or by infra-red radiation.

The invention also includes the converse of each of these methods, which consists in preparing a printing plate to print a negative of the circuit component, and making the imprint in ink to which metal will not adhere upon an insulating surface to which it will adhere, and thereafter applying leaf metal or dusting on metal powder and consolidating as above described.

The necessary intimate association of the two metals to be dusted on is better ensured by coating the metal powder of high melting point with a metal of lower melting point, which may be effected in an electrolytic bath, or, particularly in the case of alloys such as Rose metal, by

8

stirring the powder of high melting point metal into suspension in the molten low melting point alloy, and grinding to powder the solidified product. The flux may also be a coating on one of the mixed powders or on the metal-coated metal particles made as just described. If the particles are not also coated with flux there may be included in the ink of which the imprint is made ingredients such as rosin oils to serve as flux.

If desired the less readily fusible constituent metal required to produce a consolidated imprint, or both metals, may form the pigment of the printing ink. In the former case the metal particles in the ink may be coated with flux and the second metal ingredient may be added in any of the ways above described, by hot soldering, by spraying, or by deposition from vapour. In the latter case the pigment may consist of particles of less readily fusible metal coated with fusible metal and if desired with flux also, and consolidation will be effected by simple heating of the print, say by a high frequency magnetic field.

The printing plate may be a photographic plate or film, in which case the imprint is made by contact printing or projection upon a sensitised surface. For example a metal plate may be gelatine coated as in zincography, and printed from a negative of the circuit component. The coating is hardened where it is exposed to light and elsewhere may be washed away, and the metal so uncovered can be etched away, preferably in stages. Or the hardened gelatine may be inked, and dusted with metal which is consolidated as above described. The imprint may be transferred to a permanent base prior to consolidation, and this necessary if the gelatine could not withstand the consolidation process chosen.

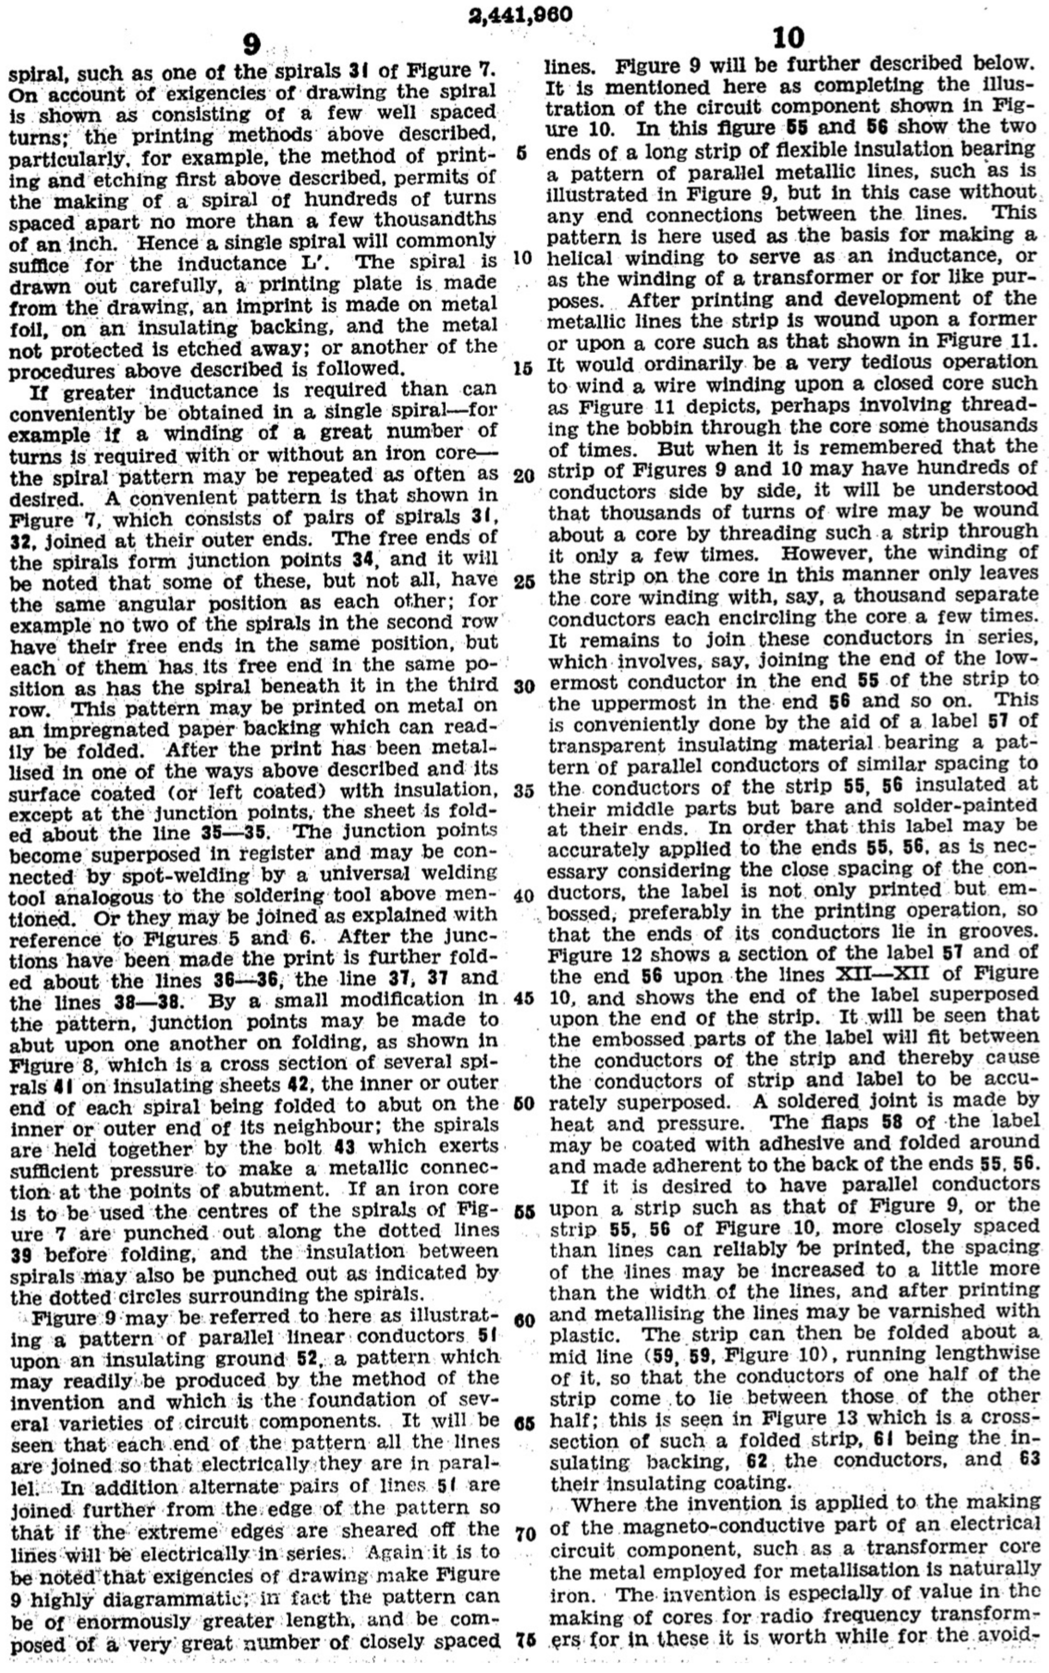
Any of the processes above described may include or be followed by the step of transferring the imprint from a temporary to a permanent base, provided due regard be paid to the requirements of that step in the selection of materials.

These various methods by which an imprint of a circuit component is converted into a circuit component are to be regarded as illustrative examples only; to those acquainted with the printing art, from which most of the individual steps employed are taken, with some modification, it will be obvious that many other modified operations or modified sequences of operations may be adopted according to the nature of the circuit component that is to be made. A few of these are mentioned below in connection with the making of particular circuit components.

Reverting to the radio receiver of Figures 1 and 2, there has so far been described the production of only one of its circuit components, namely the circuit connections, which can be produced by any of the methods above described. To what extent it is convenient to employ the invention in the making of other components of the radio receiver is a question to be answered on economic grounds. The illustrative examples next described show that other components may readily be made by similar methods, and those examples will assist in indicating how the design of components may usefully be modified with a view to their being manufactured by a printing process.

The inductance L' of the antenna circuit may take the well-known if less usual form of a flat

Figure B.119: Paul Eisler produced printed circuits in 1936 and filed a detailed patent application in 1944.



spiral, such as one of the spirals 31 of Figure 7. On account of exigencies of drawing the spiral is shown as consisting of a few well spaced turns; the printing methods above described, particularly, for example, the method of printing and etching first above described, permits of the making of a spiral of hundreds of turns spaced apart no more than a few thousandths of an inch. Hence a single spiral will commonly suffice for the inductance L'. The spiral is drawn out carefully, a printing plate is made from the drawing, an imprint is made on metal foil, on an insulating backing, and the metal not protected is etched away; or another of the procedures above described is followed.

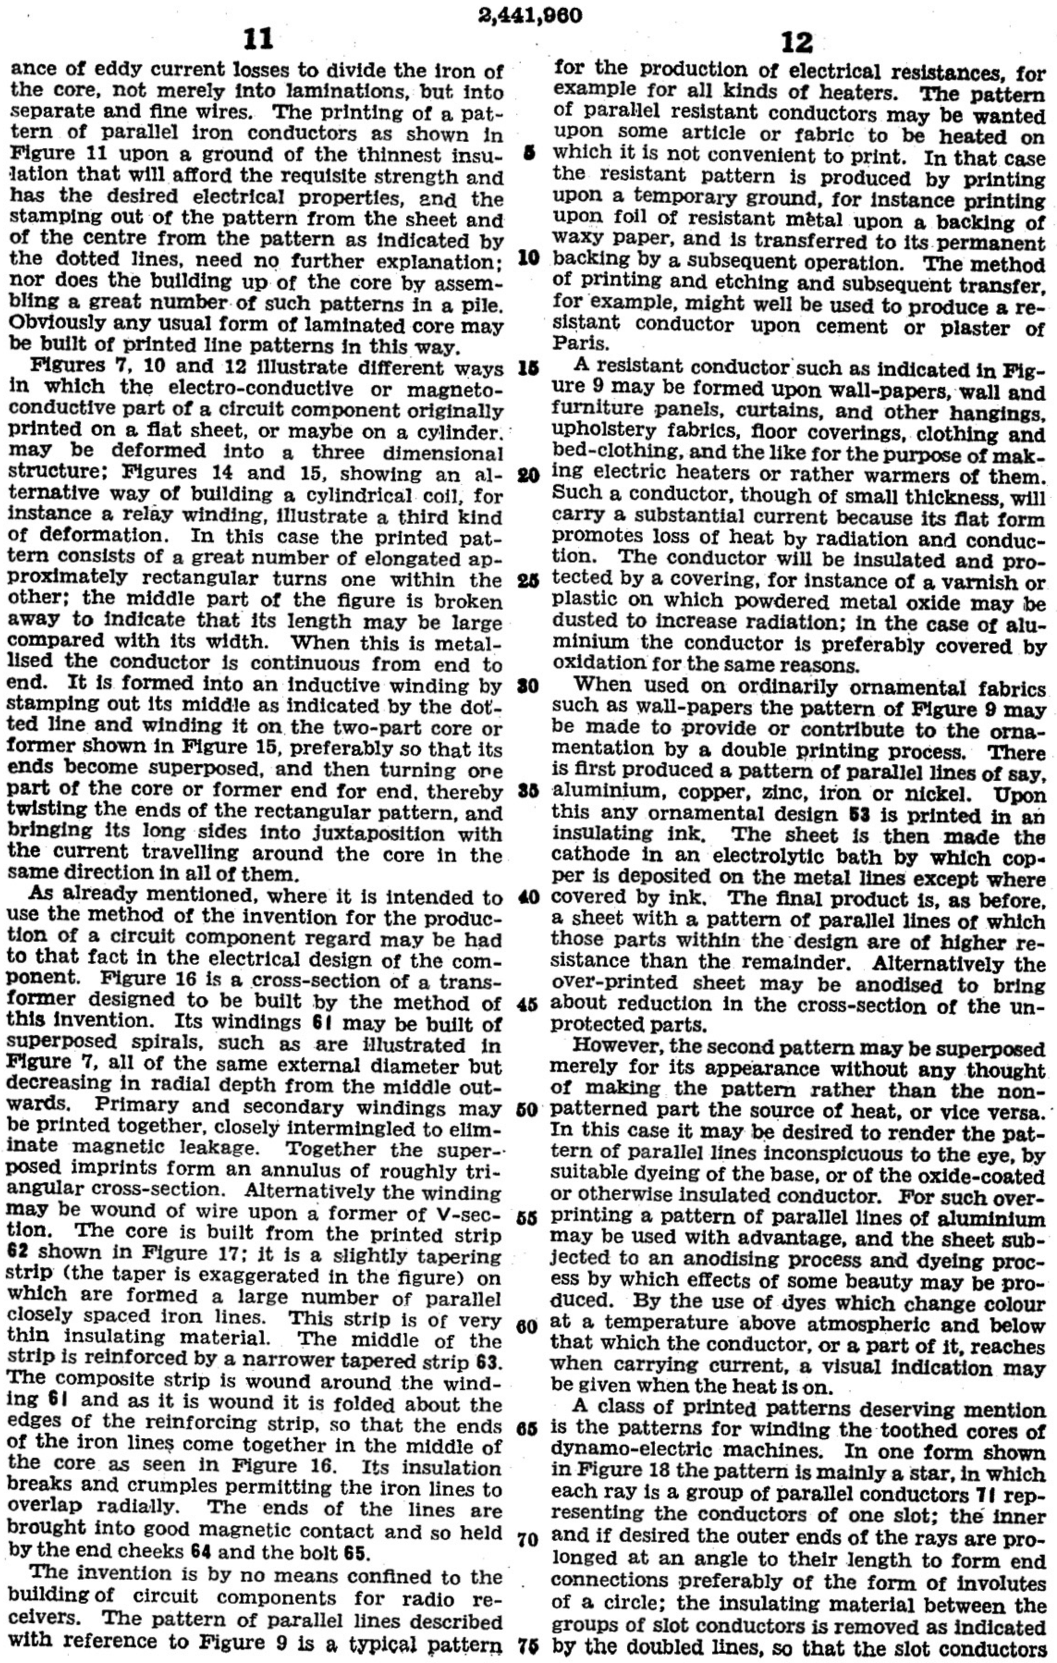
If greater inductance is required than can conveniently be obtained in a single spiral—for example if a winding of a great number of turns is required with or without an iron core—the spiral pattern may be repeated as often as desired. A convenient pattern is that shown in Figure 7, which consists of pairs of spirals 31, 32, joined at their outer ends. The free ends of the spirals form junction points 34, and it will be noted that some of these, but not all, have the same angular position as each other; for example no two of the spirals in the second row have their free ends in the same position, but each of them has its free end in the same position as has the spiral beneath it in the third row. This pattern may be printed on metal on an impregnated paper backing which can readily be folded. After the print has been metallised in one of the ways above described and its surface coated (or left coated) with insulation, except at the junction points, the sheet is folded about the line 35—35. The junction points become superposed in register and may be connected by spot-welding by a universal welding tool analogous to the soldering tool above mentioned. Or they may be joined as explained with reference to Figures 5 and 6. After the junctions have been made the print is further folded about the lines 36—36, the line 37, 37 and the lines 38—38. By a small modification in the pattern, junction points may be made to abut upon one another on folding, as shown in Figure 8, which is a cross section of several spirals 41 on insulating sheets 42, the inner or outer end of each spiral being folded to abut on the inner or outer end of its neighbour; the spirals are held together by the bolt 43 which exerts sufficient pressure to make a metallic connection at the points of abutment. If an iron core is to be used the centres of the spirals of Figure 7 are punched out along the dotted lines 39 before folding, and the insulation between spirals may also be punched out as indicated by the dotted circles surrounding the spirals.

Figure 9 may be referred to here as illustrating a pattern of parallel linear conductors 51 upon an insulating ground 52, a pattern which may readily be produced by the method of the invention and which is the foundation of several varieties of circuit components. It will be seen that each end of the pattern all the lines are joined so that electrically they are in parallel. In addition alternate pairs of lines 51 are joined further from the edge of the pattern so that if the extreme edges are sheared off the lines will be electrically in series. Again it is to be noted that exigencies of drawing make Figure 9 highly diagrammatic; in fact the pattern can be of enormously greater length, and be composed of a very great number of closely spaced lines. Figure 9 will be further described below. It is mentioned here as completing the illustration of the circuit component shown in Figure 10. In this figure 55 and 56 show the two ends of a long strip of flexible insulation bearing a pattern of parallel metallic lines, such as is illustrated in Figure 9, but in this case without any end connections between the lines. This pattern is here used as the basis for making a helical winding to serve as an inductance, or as the winding of a transformer or for like purposes. After printing and development of the metallic lines the strip is wound upon a former or upon a core such as that shown in Figure 11. It would ordinarily be a very tedious operation to wind a wire winding upon a closed core such as Figure 11 depicts, perhaps involving threading the bobbin through the core some thousands of times. But when it is remembered that the strip of Figures 9 and 10 may have hundreds of conductors side by side, it will be understood that thousands of turns of wire may be wound about a core by threading such a strip through it only a few times. However, the winding of the strip on the core in this manner only leaves the core winding with, say, a thousand separate conductors each encircling the core a few times. It remains to join these conductors in series, which involves, say, joining the end of the lowermost conductor in the end 55 of the strip to the uppermost in the end 56 and so on. This is conveniently done by the aid of a label 57 of transparent insulating material bearing a pattern of parallel conductors of similar spacing to the conductors of the strip 55, 56 insulated at their middle parts but bare and solder-painted at their ends. In order that this label may be accurately applied to the ends 55, 56, as is necessary considering the close spacing of the conductors, the label is not only printed but embossed, preferably in the printing operation, so that the ends of its conductors lie in grooves. Figure 12 shows a section of the label 57 and of the end 56 upon the lines XII—XII of Figure 10, and shows the end of the label superposed upon the end of the strip. It will be seen that the embossed parts of the label will fit between the conductors of the strip and thereby cause the conductors of strip and label to be accurately superposed. A soldered joint is made by heat and pressure. The flaps 58 of the label may be coated with adhesive and folded around and made adherent to the back of the ends 55, 56.

If it is desired to have parallel conductors upon a strip such as that of Figure 9, or the strip 55, 56 of Figure 10, more closely spaced than lines can reliably be printed, the spacing of the lines may be increased to a little more than the width of the lines, and after printing and metallising the lines may be varnished with plastic. The strip can then be folded about a mid line (59, 59, Figure 10), running lengthwise of it, so that the conductors of one half of the strip come to lie between those of the other half; this is seen in Figure 13 which is a cross-section of such a folded strip, 61 being the insulating backing, 62 the conductors, and 63 their insulating coating.

Where the invention is applied to the making of the magneto-conductive part of an electrical circuit component, such as a transformer core the metal employed for metallisation is naturally iron. The invention is especially of value in the making of cores for radio frequency transformers for in these it is worth while for the avoid-

Figure B.120: Paul Eisler produced printed circuits in 1936 and filed a detailed patent application in 1944.



2,441,960

11

ance of eddy current losses to divide the iron of the core, not merely into laminations, but into separate and fine wires. The printing of a pattern of parallel iron conductors as shown in Figure 11 upon a ground of the thinnest insulation that will afford the requisite strength and has the desired electrical properties, and the stamping out of the pattern from the sheet and of the centre from the pattern as indicated by the dotted lines, need no further explanation; nor does the building up of the core by assembling a great number of such patterns in a pile. Obviously any usual form of laminated core may be built of printed line patterns in this way.

Figures 7, 10 and 12 illustrate different ways in which the electro-conductive or magneto-conductive part of a circuit component originally printed on a flat sheet, or maybe on a cylinder, may be deformed into a three dimensional structure; Figures 14 and 15, showing an alternative way of building a cylindrical coil, for instance a relay winding, illustrate a third kind of deformation. In this case the printed pattern consists of a great number of elongated approximately rectangular turns one within the other; the middle part of the figure is broken away to indicate that its length may be large compared with its width. When this is metallised the conductor is continuous from end to end. It is formed into an inductive winding by stamping out its middle as indicated by the dotted line and winding it on the two-part core or former shown in Figure 15, preferably so that its ends become superposed, and then turning one part of the core or former end for end, thereby twisting the ends of the rectangular pattern, and bringing its long sides into juxtaposition with the current travelling around the core in the same direction in all of them.
